Table 15.307. The total bond energies of pyrazine calculated using the functional group composition and the energies of Table 15.306 compared to the experimental values [3].

## QUINOLINE

Quinoline has the formula $\mathrm{C}_{9} \mathrm{H}_{7} \mathrm{~N}$ and comprises the naphthalene molecule with one CH group replaced by a nitrogen atom which gives rise to a $C \stackrel{3 e}{=} N$ functional group. The aromatic $C \stackrel{3 e}{=} C$ and $C-H$ functional groups are equivalent to those of naphthalene given in the corresponding section with the aromaticity maintained by the electrons from nitrogen in the $C=N$ group, which is also aromatic. The $C-C$ functional group is also equivalent to that of naphthalene. The bonding in quinoline can be further considered as a linear combination of the naphthalene and pyridine groups wherein the $C \stackrel{3 e}{=} N$ group is equivalent to that of pyridine, pyrimidine, and pyrazine as given in the corresponding sections.

The symbols of the functional groups of quinoline are given in Table 15.309. The corresponding designation of the structure is shown in Figure 15.53B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of quinoline are given in Tables 15.310, 15.311, and 15.312, respectively. The total energy of quinoline given in Table 15.313 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.312 corresponding to functional-group composition of the molecule. The bond angle parameters of quinoline determined using Eqs. (15.88-15.117) are given in Table 15.314. The color scale, translucent view of the chargedensity of quinoline comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.53A.

Figure 15.53. (A) Color scale, translucent view of the charge-density of quinoline showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of quinoline.

## ISOQUINOLINE

Isoquinoline has the formula $\mathrm{C}_{9} \mathrm{H}_{7} \mathrm{~N}$ and comprises the naphthalene molecule with one CH group replaced by a nitrogen atom which gives rise to a $C \stackrel{3 e}{=} N$ functional group. Isoquinoline is also equivalent to quinoline with the nitrogen in the meta rather than the ortho position relative to the benzene ring of the molecule. The aromatic $C=C=3$ and $C-H$ functional groups are equivalent to those of naphthalene given in the corresponding section with the aromaticity maintained by the electrons from nitrogen in the $C \stackrel{3 e}{=} N$ group which is also aromatic. The $C-C$ functional group is also equivalent to that of naphthalene. The bonding in isoquinoline can be further considered as a linear combination of the naphthalene and pyridine groups wherein the $C \stackrel{3 e}{=} N$ group is equivalent to that of pyridine, pyrimidine, pyrazine, and quinoline as given in the corresponding sections.

The symbols of the functional groups of isoquinoline are given in Table 15.315. The corresponding designation of the structure is shown in Figure 15.54B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of isoquinoline are given in Tables 15.316, 15.317, and 15.318 , respectively. The total energy of isoquinoline given in Table 15.319 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.318 corresponding to functional-group composition of the molecule. The bond angle parameters of isoquinoline determined using Eqs. (15.88-15.117) are given in Table 15.320 . The color scale, translucent view of the chargedensity of isoquinoline comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.54A.

Figure 15.54. (A) Color scale, translucent view of the charge-density of isoquinoline showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of isoquinoline.

## INDOLE

Indole having the formula $\mathrm{C}_{8} \mathrm{H}_{7} \mathrm{~N}$ comprises a phenyl moiety with a conjugated five-membered ring which comprises pyrrole except that one of the double bonds is part of the aromatic ring. The structure is shown in Figure 15.55B. The aromatic $C=C$ and $C-H$ functional groups of the phenyl moiety are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The $C H, N H$, and $C_{d}=C_{e}$ groups of the pyrrole-type ring are equivalent to the corresponding groups of pyrrole, furan, and thiophene where present as given in the corresponding sections. The $C_{b}-C_{d}$ single bond of aryl carbon to the $C_{d}=C_{e}$ bond is also a functional group. This group is equivalent to the $C-C(O)$ group of benzoic acids with regard to $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}(A O / H O)$ in Eq. (15.51) and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ in Eq. (15.61) both being -1.29147 eV . This energy is a linear combination of $\frac{-1.13379 \mathrm{eV}}{2}, E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-H$ group that the $C_{b}-C_{d}$ and $C-C(O)$ groups replace, and that of an independent $C 2 s p^{3} \mathrm{HO},-0.72457 \mathrm{eV}$ (Eq. (14.151)). However, as in the case of pyrrole, the indole hybridization term $c_{2}$ is the aromatic $c_{2}\left(\right.$ benzene $\left.C 2 s p^{3} H O\right)=0.85252$ to match the aryl $C 2 s p^{3} \mathrm{HO}$, and the energy terms corresponding to oscillation in the transition state correspond to indole.

As in the case of pyrrole, the $C-N-C$-bond MO comprising a linear combination of two single bonds is solved in the same manner as a double bond with $n_{1}=2$ in Eqs. (15.51) and (15.61). The hybridization factor $c_{2}\left(\operatorname{arylC} 2 s p^{3} \mathrm{HO}\right.$ to N$)=0.84665$ (Eq. (15.171)) matches the aromatic character of the $C 2 s p^{3}$ HOs to the $N$ atom of the $N H$ group, and $C_{2}$ and $C_{2 o}$ in Eqs. (15.51) and (15.61) become that of benzene given by Eq. (15.162), $C_{2}\left(\right.$ benzene $\left.C 2 s p^{3} H O\right)=0.85252$. Furthermore, $\Delta E_{H_{2} M O}(A O / H O)$ in Eq. (15.51) and $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ in Eq. (15.61) are both -2.42526 eV which is a linear combination of $\frac{-1.13379 \mathrm{eV}}{2}, E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ of the $C-H$ group that the $C_{c}-N$ bond replaces, and -1.85836 eV (Eq. (14.513)) which is equivalent to the corresponding component of the $C-N-C$-bond of pyrrole.

The symbols of the functional groups of indole are given in Table 15.321. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and ( $15.17-15.65$ )) parameters of indole are given in Tables $15.322,15.323$, and 15.324 , respectively. The total energy of indole given in Table 15.325 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.324 corresponding to functional-group composition of the molecule. The bond angle parameters of indole determined using Eqs. (15.88-15.117) are given in Table 15.326. The color scale, translucent view of the charge-density of indole comprising the concentric shells of atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$ type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.55A.

Figure 15.55. (A) Color scale, translucent view of the charge-density of indole showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of indole.

## ADENINE

Adenine having the formula $C_{5} H_{5} N_{5}$ comprises a pyrimidine moiety with an aniline-type moiety and a conjugated fivemembered ring, which comprises imidazole except that one of the double bonds is part of the aromatic ring. The structure is
shown in Figure 15.56B. The aromatic $C=C, C-H$, and $C=N$ functional groups of the pyrimidine moiety are equivalent to those of pyrimidine as given in the corresponding section. The $\mathrm{CH}, \mathrm{NH}, C_{d}-N_{e}$, and $N_{e}=C_{e}$ groups of the imidazole-type ring are equivalent to the corresponding groups of imidazole as given in the corresponding section. The $C-N-C$ functional group of the imidazole-type ring is equivalent to the corresponding group of indole having the same structure with the $\mathrm{C}-\mathrm{N}-\mathrm{C}$ group bonding to aryl and alkenyl groups. The $\mathrm{NH}_{2}$ and $C_{a}-N_{a}$ functional groups of the aniline-type moiety are equivalent to those of aniline as given in the corresponding section except that $\Delta E_{\mathrm{H}_{2} M O}(A O / H O)$ of the $C_{a}-N_{a}$ group is equal to twice $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$, and to meet the equipotential condition of the union of the $C-N H_{2}$-type-ellipsoidalMO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.60) for the $C-N$-bond MO given by Eqs. (15.77), (15.79), and (15.162) is:

$$
\begin{equation*}
c_{2}\left(\text { arylC2sp }{ }^{3} H O \text { to } N\right)=\frac{E(N)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(\operatorname{arylC} 2 s p^{3} H O\right)=\frac{-14.53414 \mathrm{eV}}{-15.95955 \mathrm{eV}}(0.85252)=0.77638 \tag{15.173}
\end{equation*}
$$

The symbols of the functional groups of adenine are given in Table 15.327. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of adenine are given in Tables $15.328,15.329$, and 15.330 , respectively. The total energy of adenine given in Table 15.331 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.330 corresponding to functional-group composition of the molecule. The bond angle parameters of adenine determined using Eqs. (15.88-15.117) are given in Table 15.332. The color scale, chargedensity of adenine comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.56A.

Figure 15.56. (A) Color scale, charge-density of adenine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure and atomic designation of adenine.

## THYMINE

Thymine having the formula $C_{5} H_{6} N_{2} O_{2}$ is a pyrimidine with carbonyl substitutions at positions $C_{a}$ and $C_{b}$ and a methyl substitution at position $C_{d}$ further comprising a vinyl group as shown in Figure 15.57B. Each $C=O$, adjacent $C-N$, and $N H$ functional group is equivalent to the corresponding group of alkyl amides. The methyl-vinyl moiety is equivalent to the $\mathrm{CH}_{3}$, $-C(C)=C, C H$, and $C=C$ functional groups of alkenes. Thymine further comprises $N_{b} H$ and $C_{b}-N_{c}-C_{c}$ groups that are equivalent to the corresponding groups of imidazole as given in the corresponding section. The $C_{a}-C_{d}$ bond comprises another functional group that is equivalent to the $C_{a}-C_{d}$ group of guanine.

The symbols of the functional groups of thymine are given in Table 15.333. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of thymine are given in Tables $15.334,15.335$, and 15.336 , respectively. The total energy of thymine given in Table 15.337 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.336 corresponding to functional-group composition of the molecule. The bond angle parameters of thymine determined using Eqs. (15.88-15.117) are given in Table 15.338. The color scale, chargedensity of thymine comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.57A.

Figure 15.57. (A) Color scale, charge-density of thymine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure and atom designation of thyamine.

## GUANINE

Guanine having the formula $C_{5} H_{5} \mathrm{~N}_{5} \mathrm{O}$ is a purine with a carbonyl substitution at position $C_{a}$, and a primary amine moiety is at position $C_{b}$ as shown in Figure 15.58B. The carbonyl functional group is equivalent to that of alkyl amides and the $\mathrm{NH}_{2}$ and $C_{b}-N_{a}$ functional groups of the primary amine moiety are equivalent to the $\mathrm{NH}_{2}$ and $\mathrm{C}_{a}-N_{a}$ functional groups of adenine. Guanine further comprises an imidazole moiety wherein the $C H, N_{d} H, C_{d}=C_{c}, C_{d}-N_{e}, N_{e}=C_{e}$, and $C_{c}-N_{d}-C_{e}$ groups of the imidazole-type ring are equivalent to the corresponding groups of imidazole as given in the corresponding section. The six-membered ring also comprises the groups $C_{a}-N_{b}-C_{b}, N_{b} H, N_{c}=C_{c}$, and $C_{c}-N_{d}$ that are equivalent to the corresponding imidazole and adenine functional groups. The $C_{a}-C_{d}$ bond comprises another functional group that is the $C_{60}{ }^{-}$ single-bond functional group except that $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=0$ in order to match the energies of the single and doublebonded moieties within the molecule.

The symbols of the functional groups of guanine are given in Table 15.339. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of guanine are given in Tables $15.340,15.341$, and 15.342 , respectively. The total energy of guanine given in Table 15.343 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.342 corresponding to functional-group composition of the molecule. The bond angle parameters of guanine determined using Eqs. (15.88-15.117) are given in Table 15.344. The color scale, chargedensity of guanine comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.58A.

Figure 15.58. (A) Color scale, charge-density of guanine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure and atomic designation of guanine.

Table 15.339. The symbols of functional groups of guanine.

| Functional Group | Group Symbol |
| :--- | :--- |
| $C_{a}=O$ (alkyl amide) | $\mathrm{C}=\mathrm{O}$ |
| $C_{b}-N_{a}$ | $\mathrm{C}-\mathrm{N}$ (a) |
| $\mathrm{NH}_{2}$ group | $\mathrm{NH}_{2}$ |
| $C_{c}=C_{d}$ double bond | $\mathrm{C}=\mathrm{C}$ |
| $C_{a}-C_{d}$ | $\mathrm{C}-\mathrm{C}$ |
| $N_{e}=C_{e} \quad N_{c}=C_{b}$ double bond | $\mathrm{N}=\mathrm{C}$ |
| $C_{d}-N_{e} \quad C_{c}-N_{c}$ | $\mathrm{C}-\mathrm{N} \mathrm{(b)}$ |
| $C_{c}-N_{d}-C_{e} \quad C_{a}-N_{b}-C_{b}$ | $\mathrm{C}-\mathrm{N}-\mathrm{C}$ |
| $N_{d} H \quad N_{b} H$ group | NH |
| $C_{e} H$ | CH |

## CYTOSINE

Cytosine having the formula $C_{4} H_{5} N_{3} O$ is a pyrimidine with a carbonyl substitution at position $C_{b}$, and a primary amine moiety is at position $C_{a}$ as shown in Figure 15.59B. The carbonyl and adjacent $C_{b}-N_{b}$ functional groups are equivalent to the corresponding groups of alkyl amides. The $\mathrm{NH}_{2}$ and $\mathrm{C}_{a}-\mathrm{N}_{a}$ functional groups of the primary amine moiety are equivalent to the $\mathrm{NH}_{2}$ and $\mathrm{C}_{a}-\mathrm{N}_{a}$ functional groups of adenine. The vinyl moiety, $\mathrm{HC}_{c}=C_{d} H$, comprises $\mathrm{C}=\mathrm{C}$ and CH functional groups that are equivalent to the corresponding alkene groups. Cytosine further comprises $N_{b}=C_{a}, N_{c} H$, and $C_{b}-N_{c}-C_{c}$ groups that are equivalent to the corresponding groups of imidazole as given in the corresponding section. The $C_{a}-C_{d}$ bond comprises another functional group that is equivalent to the $C_{a}-C_{d}$ group of guanine and thymine except that $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is equivalent to the contribution of a $C 2 s p^{3} \mathrm{HO}$ of an alkane, -0.92918 eV (Eq. (14.513)), in order to match the energies of the single and double-bonded moieties within the molecule.

The symbols of the functional groups of cytosine are given in Table 15.345. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of cytosine are given in Tables $15.346,15.347$, and 15.348 , respectively. The total energy of cytosine given in Table 15.349 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.348 corresponding to functional-group composition of the molecule. The bond angle parameters of cytosine determined using Eqs. (15.88-15.117) are given in Table 15.350. The color scale, chargedensity of cytosine comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.59A.

Figure 15.59. (A) Color scale, charge-density of cytosine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure and atomic designation of cytosine.

Table 15.345. The symbols of functional groups of cytosine.

| Functional Group | Group Symbol |
| :---: | :---: |
| $C_{a}-N_{a}$ | $C-N$ (a) |
| $\mathrm{NH}_{2}$ group | $\mathrm{NH}_{2}$ |
| $N_{b}=C_{a}$ double bond | $N=C$ |
| $C_{b}=O \quad$ (alkyl amide) | $C=O$ |
| $C_{b}-N_{b}$ amide | $C-N$ (b) |
| $C_{c}=C_{d}$ double bond | $C=C$ |
| $\mathrm{C}_{c} \mathrm{H} \quad \mathrm{C}_{d} H$ | CH |
| $C_{a}-C_{d}$ | C-C |
| $\mathrm{C}_{b}-\mathrm{N}_{c}-\mathrm{C}_{c}$ | $\mathrm{C}-\mathrm{N}-\mathrm{C}$ |
| $N_{c} \mathrm{H}$ group | NH |

## ALKYL PHOSPHINES $\left(\left(C_{n} H_{2 n+1}\right)_{3} P, n=1,2,3,4,5 \ldots \infty\right)$

The alkyl phosphines, $\left(C_{n} H_{2 n+1}\right)_{3} P$, comprise a $P-C$ functional group. The alkyl portion of the alkyl phosphine may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of each chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl phosphines are equivalent to those in branched-chain alkanes. The $P-C$ group may further join the $P 3 s p^{3} \mathrm{HO}$ to an aryl HO .

As in the case of carbon, the bonding in the phosphorous atom involves $s p^{3}$ hybridized orbitals formed, in this case, from the $3 p$ and $3 s$ electrons of the outer shells with five $P 3 s p^{3}$ HOs rather than four $C 2 s p^{3}$ HOs. The $P-C$ bond forms between $P 3 s p^{3}$ and $C 2 s p^{3}$ HOs to yield phosphines. The semimajor axis $a$ of the $P-C$ functional group is solved using Eq. (15.51). Using the semimajor axis and the relationships between the prolate spheroidal axes, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in Organic Molecular Functional Groups and Molecules section.

The energy of phosphorous is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). A minimum energy is achieved while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical ( $O H$ ) section with hybridization of the phosphorous atom such that in Eqs. (15.51) and (15.61), the sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $P 3 s p^{3}$ shell as in the case of the corresponding carbon and silicon molecules.

The $P$ electron configuration is $[N e] 3 s^{2} 3 p^{3}$ corresponding to the ground state ${ }^{4} S_{3 / 2}$, and the $3 s p^{3}$ hybridized orbital arrangement after Eq. (13.422) is:

\[

\]

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the five electrons. The sum $E_{T}\left(P, 3 s p^{3}\right)$ of experimental energies [38] of $P, P^{+}, P^{2+}, P^{3+}$, and $P^{4+}$ is:

$$
\begin{aligned}
E_{T}\left(P, 3 s p^{3}\right) & =65.0251 \mathrm{eV}+51.4439 \mathrm{eV}+30.2027 \mathrm{eV}+19.7695 \mathrm{eV}+10.48669 \mathrm{eV} \\
& =176.92789 \mathrm{eV}
\end{aligned}
$$

(15.175)

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 s p^{3}}$ of the $P 3 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{3 s p^{3}}=\sum_{n=10}^{14} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 176.92789 \mathrm{eV})}=\frac{15 e^{2}}{8 \pi \varepsilon_{0}(e 176.92789 \mathrm{eV})}=1.15350 a_{0} \tag{15.176}
\end{equation*}
$$

where $Z=15$ for phosphorous. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(P, 3 s p^{3}\right)$ of the outer electron of the $P 3 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(P, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.15350 a_{0}}=-11.79519 \mathrm{eV} \tag{15.177}
\end{equation*}
$$

During hybridization, the spin-paired $3 s$ electrons are promoted to the $P 3 s p^{3}$ shell as paired electrons at the radius $r_{3 s p^{3}}$ of the $P 3 s p^{3}$ shell. The energy for the promotion is the difference in the magnetic energy given by Eq. (15.15) at the initial radius of the $3 s$ electrons and the final radius of the $P 3 s p^{3}$ electrons. From Eq. (10.255) with $Z=15$, the radius $r_{12}$ of $P 3 s$ shell is

$$
\begin{equation*}
r_{12}=1.09443 a_{0} \tag{15.178}
\end{equation*}
$$

Using Eqs. (15.15) and (15.178), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}}\left(\frac{1}{\left(r_{12}\right)^{3}}-\frac{1}{\left(r_{3 s p^{3}}\right)^{3}}\right)=8 \pi \mu_{o} \mu_{B}^{2}\left(\frac{1}{\left(1.09443 a_{0}\right)^{3}}-\frac{1}{\left(1.15350 a_{0}\right)^{3}}\right)=0.01273 \mathrm{eV} \tag{15.179}
\end{equation*}
$$

Using Eqs. (15.177) and (15.179), the energy $E\left(P, 3 s p^{3}\right)$ of the outer electron of the $P 3 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(P, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}}\left(\frac{1}{\left(r_{12}\right)^{3}}-\frac{1}{\left(r_{3 s p^{3}}\right)^{3}}\right)=-11.79519 \mathrm{eV}+0.01273 \mathrm{eV}=-11.78246 \mathrm{eV} \tag{15.180}
\end{equation*}
$$

For the $P-C$ functional group, hybridization of the $2 s$ and $2 p$ AOs of each $C$ and the $3 s$ and $3 p$ AOs of each $P$ to form single $2 s p^{3}$ and $3 s p^{3}$ shells, respectively, forms an energy minimum, and the sharing of electrons between the $C 2 s p^{3}$ and $P 3 s p^{3}$ HOs to form a MO permits each participating orbital to decrease in radius and energy. In branched-chain alkyl phosphines, the energy of phosphorous is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{2}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $C_{2}$ parameter. Then, the $C 2 s p^{3}$ HO has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV} \quad$ (Eq. (15.25)), and the $P 3 s p^{3} \quad \mathrm{HO}$ has an energy of $E\left(P, 3 s p^{3}\right)=-11.78246 \mathrm{eV}$ (Eq. (15.180)). To meet the equipotential condition of the union of the $P-C H_{2}$-type-ellipsoidalMO with these orbitals, the hybridization factor $C_{2}$ of Eq. (15.61) for the $P-C$-bond MO given by Eqs. (15.77), (15.79), and (13.430) is:

$$
\begin{equation*}
C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } P 3 s p^{3} \mathrm{HO}\right)=\frac{E\left(P, 3 s p^{3}\right)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-11.78246 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.73885 \tag{15.181}
\end{equation*}
$$

The energy of the $P-C$-bond MO is the sum of the component energies of the $H_{2}$-type ellipsoidal MO given in Eq. (15.51) with $E(A O / H O)=E\left(P, 3 s p^{3}\right)$ given by Eq. (15.180), and $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ is one half -0.72457 eV given by Eq. (14.151) in order to match the energies of the carbon and phosphorous HOs.

The symbols of the functional groups of branched-chain alkyl phosphines are given in Table 15.351. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl phosphines are given in Tables 15.352, 15.353, and 15.354, respectively. The total energy of each alkyl phosphine given in Table 15.355 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.354 corresponding to functionalgroup composition of the molecule. The bond angle parameters of alkyl phosphines determined using Eqs. (15.88-15.117) are given in Table 15.356. The color scale, charge-density of exemplary alkyl phosphine, triphenylphosphine, comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.60.

Figure 15.60. Color scale, charge-density of triphenylphosphine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (A) Top view. (B) Side view.

## ALKYL PHOSPHITES ( $\left.\left(C_{n} H_{2 n+1} O\right)_{3} P, n=1,2,3,4,5 \ldots \infty\right)$

The alkyl phosphites, $\left(\mathrm{C}_{n} \mathrm{H}_{2 n+1} \mathrm{O}\right)_{3} P$, comprise $\mathrm{P}-\mathrm{O}$ and $\mathrm{C}-\mathrm{O}$ functional groups. The alkyl portion of the alkyl phosphite may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of each chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl phosphites are equivalent to those in branched-chain alkanes.

The ether portion comprises two types of $C-O$ functional groups, one for methyl or t-butyl groups corresponding to the $C$, and the other for general alkyl groups that are equivalent to those in the Ethers section. The $P-O$ bond forms between the $P 3 s p^{3} \mathrm{HO}$ and an $O 2 p$ AO to yield phosphites. The semimajor axis $a$ of the $P-O$ functional group is solved using Eq. (15.51). Using the semimajor axis and the relationships between the prolate spheroidal axes, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in Organic Molecular Functional Groups and Molecules section.

For the $P-O$ functional group, hybridization the $3 s$ and $3 p$ AOs of each to form a single $3 s p^{3}$ shell forms an energy minimum, and the sharing of electrons between the $O 2 p \mathrm{AOs}$ and $P 3 s p^{3} \mathrm{HOs}$ to form a MO permits each participating orbital to decrease in radius and energy. The $O$ AO has an energy of $E(O)=-13.61805 \mathrm{eV}$, and the $P 3 s p^{3} \mathrm{HO}$ has an energy of $E\left(P, 3 s p^{3}\right)=-11.78246 \mathrm{eV}$ (Eq. (15.180)). In branched-chain alkyl phosphites, the energy matching condition is determined by the $c_{2}$ and $C_{2}$ parameters of Eq. (15.51) given by Eqs. (15.77), (15.79), and (13.430).

$$
\begin{equation*}
c_{2} \text { and } C_{2}\left(O 2 p A O \text { to } P 3 s p^{3} H O\right)=\frac{E\left(P, 3 s p^{3}\right)}{E(O, 2 p)} c_{2}\left(C 2 s p^{3} H O\right)=\frac{-11.78246 \mathrm{eV}}{-13.61805 \mathrm{eV}}(0.91771)=0.79401 \tag{15.182}
\end{equation*}
$$

The energy of the $P-O$-bond MO is the sum of the component energies of the $H_{2}$-type ellipsoidal MO given in Eq. (15.51) with $E(A O / H O)$ being $E\left(P, 3 s p^{3}\right)$ given by Eq. (23.180), and $E_{T}\left(\right.$ atom -atom, $\left.m s p^{3} . A O\right)$ is equivalent to that of single bond, -1.44914 eV , given by twice Eq. (14.151) in order to match the energies of the oxygen AO with the phosphorous and carbon HOs.

The symbols of the functional groups of branched-chain alkyl phosphites are given in Table 15.357. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl phosphites are given in Tables $15.358,15.359$, and 15.360 , respectively. The total energy of each alkyl phosphite given in Table 15.361 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.360 corresponding to functionalgroup composition of the molecule. The bond angle parameters of alkyl phosphites determined using Eqs. (15.88-15.117) are given in Table 15.362. The color scale, charge-density of exemplary alkyl phosphite, tri-isopropyl phosphite, comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.61.

Figure 15.61. Color scale, charge-density of tri-isopropyl phosphite showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei.

## ALKYL PHOSPHINE OXIDES ( $\left.\left(C_{n} H_{2 n+1}\right)_{3} P=O, n=1,2,3,4,5 \ldots \infty\right)$

The alkyl phosphine oxides, $\left(C_{n} H_{2 n+1}\right)_{3} P=O$, comprise $P-C$ and $P=O$ functional groups. The alkyl portion of the alkyl phosphine oxide may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of each chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $\mathrm{C}-\mathrm{C}$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl phosphine oxides are equivalent to those in branched-chain alkanes.

The $P-C$ functional group is equivalent to that of alkyl phosphines. The $P=O$ bond forms between the $P 3 s p^{3}$ HO and an $O 2 p$ AO to yield phosphine oxides. The semimajor axis $a$ of the $P=O$ functional group is solved using Eq. (15.51). Using the semimajor axis and the relationships between the prolate spheroidal axes, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in Organic Molecular Functional Groups and Molecules section.
For the $P=O$ functional group, hybridization the $3 s$ and $3 p$ AOs of each $P$ to form a single $3 s p^{3}$ shells forms an energy minimum, and the sharing of electrons between the $O 2 p$ AOs and $P 3 s p^{3} \mathrm{HOs}$ to form a MO permits each participating orbital to decrease in radius and energy. In branched-chain alkyl phosphine oxides, the energy of phosphorous is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). The energy matching condition is determined by the $c_{2}$ parameter given by Eq. (15.182). The energy of the $P=O$-bond MO is the sum of the component energies of the $H_{2}$ type ellipsoidal MO given in Eq. (15.51) with $E(A O / H O)$ being twice $E\left(P, 3 s p^{3}\right)$ given by Eq. (15.180) corresponding to the double bond, and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is equivalent to that of an alkene double bond, -2.26758 eV , given by Eq. (14.247) in order to match the energies of the carbon and phosphorous HOs and the oxygen AO.

The symbols of the functional groups of branched-chain alkyl phosphine oxides are given in Table 15.363. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl phosphine oxides are given in Tables 15.364, 15.365, and 15.366, respectively. The total energy of each alkyl phosphine oxide given in Table 15.367 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.366 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl phosphine oxides determined using Eqs. (15.88-15.117) are given in Table 15.368. The color scale, charge-density of exemplary alkyl phosphine oxide, trimethylphosphine oxide, comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.62.

Figure 15.62. Color scale, charge-density of trimethylphosphine oxide showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. ## ALKYL PHOSPHATES $\left(\left(C_{n} H_{2 n+1} O\right)_{3} P=O, \quad n=1,2,3,4,5 \ldots \infty\right)$

The alkyl phosphates, $\left(C_{n} H_{2 n+1} O\right)_{3} P=O$, comprise $P=O, P-O$, and $C-O$ functional groups. The $P=O$ functional group is equivalent to that of alkyl phosphine oxides. The $P-O$ and $C-O$ functional groups are equivalent to those of alkyl phosphites. The alkyl portion of the alkyl phosphate may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of each chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne ( CH ) functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The $n$-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl phosphates are equivalent to those in branched-chain alkanes.

The symbols of the functional groups of branched-chain alkyl phosphates are given in Table 15.369. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl phosphates are given in Tables 15.370, 15.371, and 15.372, respectively. The total energy of each alkyl phosphate given in Table 15.373 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.372 corresponding to functionalgroup composition of the molecule. The bond angle parameters of alkyl phosphates determined using Eqs. (15.88-15.117) are given in Table 15.374. The color scale, charge-density of exemplary alkyl phosphate, tri-isopropyl phosphate, comprising of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.63.

Figure 15.63. Color scale, charge-density of tri-isopropyl phosphate showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei.

Table 15.369. The symbols of functional groups of alkyl phosphates.

## ORGANIC AND RELATED IONS ( $\mathrm{RCO}_{2}^{-}, \mathrm{ROSO}_{3}^{-}, \mathrm{NO}_{3}^{-},(\mathrm{RO})_{2} \mathrm{PO}_{2}^{-},(\mathrm{RO})_{3} \mathrm{SiO}^{-}$,

 $\left(\mathrm{R}_{2} \mathrm{Si}^{2}\left(\mathrm{O}^{-}\right)_{2}, \mathrm{RNH}_{3}^{+}, \mathrm{R}_{2} \mathrm{NH}_{2}^{+}\right.$)Proteins comprising amino acids with amino and carboxylic acid groups are charged at physiological pH . Deoxyribonucleic acid (DNA), the genetic material of living organisms also comprises negatively charged phosphate groups. Thus, the bonding of organic ions is considered next. The molecular ions also comprise functional groups that have an additional electron or are deficient by an electron in the cases of monovalent molecular anions and cations, respectively. The molecular chemical bond typically comprises an even integer number of paired electrons, but with an excess of deficiency, the bonding may involve an odd number of electrons, and the electrons may be distributed over multiple bonds, solved as a linear combination of standard bonds. As given in the Benzene Molecule section and other sections on aromatic molecules such as naphthalene, toluene, chlorobenzene, phenol, aniline, nitrobenzene, benzoic acid, pyridine, pyrimidine, pyrazine, quinoline, isoquinoline, indole, and adenine, the paired electrons of MOs may be distributed over a linear combination of bonds such that the bonding between two atoms involves less than an integer multiple of two electrons. Specifically, the results of the derivation of the parameters of the benzene molecule given in the Benzene Molecule ( $\mathrm{C}_{6} \mathrm{H}_{6}$ ) section was generalized to any aromatic functional group of aromatic and heterocyclic compounds in the Aromatic and Heterocyclic Compounds section. Ethylene serves as a basis element for the $C \stackrel{3 e}{=} C$ bonding of the aromatic bond wherein each of the $C=C$ aromatic bonds comprises $(0.75)(4)=3$ electrons according to Eq. (15.161). Thus, in these aromatic cases, three electrons can be assigned to a given bond between two atoms wherein the electrons of the linear combination of bonded atoms are paired and comprise an integer multiple of two.

In graphite, the minimum energy structure with equivalent carbon atoms wherein each carbon forms bonds with three other such carbons requires a redistribution of charge within an aromatic system of bonds. Considering that each carbon contributes four bonding electrons, the sum of electrons of a vertex-atom group is four from the vertex atom plus two from each of the two atoms bonded to the vertex atom where the latter also contribute two each to the juxtaposed group. These eight electrons are distributed equivalently over the three bonds of the group such that the electron number assignable to each bond is $\frac{8}{3}$. Thus, the $C \stackrel{8 / 3 e}{=} C$ functional group of graphite comprises the aromatic bond with the exception that the electron-number per bond is $\frac{8}{3}$.

As given in the Bridging Bonds of Boranes section and the Bridging Bonds of Organoaluminum Hydrides section, other examples of electron deficient bonding involving two paired electrons centered on three atoms are three-center bonds as opposed to the typical single bond, a two-center bond. The $B 2 s p^{3}$ HOs comprise four orbitals containing three electrons as given by Eq. (23.1) that can form three-center as well as two-center bonds. The designation for a three-center bond involving two $B 2 s p^{3}$ HOs and a $H 1 s \mathrm{AO}$ is $B-H-B$, and the designation for a three-center bond involving three $B 2 s p^{3} \mathrm{HOs}$ is $B-B-B$. In the aluminum case, each $A l-H-A l$-bond MO and $A l-C-A l$-bond MO comprises the corresponding single bond and forms with further sharing of electrons between each $A l 3 s p^{3} \mathrm{HO}$ and each $H 1 s \mathrm{AO}$ and $C 2 s p^{3} \mathrm{HO}$, respectively. Thus, the geometrical and energy parameters of the three-center bond are equivalent to those of the corresponding two-center bonds except that the bond energy is increased in the former case since the donation of electron density from the unoccupied $A l 3 s p^{3}$ HO to each $A l-H-A l$-bond MO and $A l-C-A l$-bond MO permits the participating orbital to decrease in size and energy.

To match the energies of the AOs and MOs of the ionic functional group with the others within the molecular ion, the bonding in organic ions comprises a standard bond that serves as basis element and retains the same geometrical characteristics as that standard bond. In the case of organic oxyanions, the $A-O^{-}(A=C, S, N, P, S i)$ bond is intermediate between a single and double bond, and the latter serves as a basis element. Similar to the case of the $C=C$ aromatic bond wherein ethylene is the basis element, the $A=O$-bond functional group serves as the basis element for the $A-O^{-}$functional group of the oxyanion of carboxylates, sulfates, nitrates, phosphates, silanolates, and siloxanolates. This oxyanion group designated by $A^{3 e}=O^{-}$comprises $(0.75)(4)=3$ electrons after Eq. (15.161). Thus, the energy parameters of the $A^{3 e}=O^{-}$functional group are given by the factor of $(0.75)(4)=3$ times those of the corresponding $A=O$ functional group, and the geometric parameters are the same. The $C=O, S=O, N=O_{2}, P=O$, and $S i=O$ basis elements are given in the Carboxylic Acids, Sulfates, Alkyl Nitrates, Phosphates, and Silicon Oxides, Silicic Acids, Silanols, Siloxanes and Disiloxanes sections, respectively. A convenient means to obtain the final group energy parameters of $E_{T}($ Group $)$ and $E_{D}($ Group $)$ is by using Eqs. (15.165-15.166) with $f_{1}=0.75$ :

$$
\left.\begin{array}{l}
E_{T}(\text { Group })= \\
f_{1}\left(\begin{array}{l}
\text { E(basis energies })+E_{T}\left(\text { atom }- \text { atom }, m s p^{3} . A O\right) \\
-31.63536831 \mathrm{eV} \sqrt{\frac{\sqrt{\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{o} R^{3}}}}{m_{e}}}
\end{array} n_{1}^{m_{e} c^{2}} \bar{E}_{\text {Kvib }}+c_{3} \frac{8 \pi \mu_{o} \mu_{B}^{2}}{r^{3}}\right. \tag{15.184}
\end{array}\right)
$$

where $c_{4}$ is $(0.75)(4)=3$ when $c_{5}=0$ and otherwise $c_{4}$ is $(0.75)(2)=1.5$ and $c_{5}$ is $(0.75)(2)=1.5$.
The nature of the bonding of the amino functional group of protonated amines is similar to that in $H_{3}^{+}$. As given in the Triatomic Molecular Hydrogen-type Ion ( $H_{3}^{+}$) section, $H_{3}^{+}$comprises two indistinguishable spin-paired electrons bound by three protons. The ellipsoidal molecular orbital (MO) satisfies the boundary constraints as shown in the Nature of the Chemical Bond of Hydrogen-Type Molecules section. Since the protons are indistinguishable, ellipsoidal MOs about each pair of protons taken one at a time are indistinguishable. $H_{3}^{+}$is then given by a superposition or linear combinations of three equivalent ellipsoidal MOs that form an equilateral triangle where the points of contact between the prolate spheroids are equivalent in energy and charge density. Due to the equivalence of the $H_{2}$-type ellipsoidal MOs and the linear superposition of their energies, the energy components defined previously for the $H_{2}$ molecule, Eqs. (11.207-11.212) apply in the case of the corresponding $H_{3}^{+}$ molecular ion. And, each molecular energy component is given by the integral of corresponding force in Eq. (13.5). Each energy component is the total for the two equivalent electrons with the exception that the total charge of the two electrons is normalized over the three basis set $H_{2}$-type ellipsoidal MOs. Thus, the energies (Eqs. (13.12-13.17)) are those given in the Energies of Hydrogen-Type Molecules section with the electron charge, where it appears, multiplied by a factor of $3 / 2$, and the three sets of equivalent proton-proton pairs give rise to a factor of three times the proton-proton repulsion energy given by Eq. (11.208).

With the protonation of the imidogen $(N H)$ functional group, the minimum energy structure with equivalent hydrogen atoms comprises two protons bound to $N$ by two paired electrons, one from $H$ and one from $N$ with the MO matched to the $N 2 p$ AO. These two electrons are distributed equivalently over the two $H-N$ bonds of the group such that the electron number assignable to each bond is $\frac{2}{2}$. Thus, the $\mathrm{NH}_{2}^{+}$functional group has the imidogen energy parameters with the exception that each energy term is multiplied by the factor 2 due to the two bonds with electron-number per bond of $\frac{2}{2}$ and has the same geometric parameters as the $N H$ functional group given in the Secondary Amines section. A convenient means to obtain the final group energy parameters of $E_{T}($ Group $)$ and $E_{D}($ Group $)$ is by using Eqs. (15.165-15.166) (Eqs. (15.183-15.184)) with $f_{1}=2$ and $c_{4}$ and $c_{5}$ multiplied by two.

With the protonation of the amidogen $\left(\mathrm{NH}_{2}\right)$ functional group, the minimum energy structure with equivalent hydrogen atoms comprises three protons bound to $N$ by four paired electrons, two from $2 H$ and two from $N$ with the MO matched to the $N 2 p \mathrm{AO}$. These four electrons are distributed equivalently over the three $H-N$ bonds of the group such that the electron number assignable to each bond is $\frac{4}{3}$. Thus, the $\mathrm{NH}_{3}^{+}$functional group has the amidogen energy parameters with the exception that each energy term is multiplied by the factor $\frac{3}{2}$ due to the three bonds with electron-number per bond of $\frac{4}{3}$ and has the same geometric parameters as the $\mathrm{NH}_{2}$ functional group given in the Primary Amines section. A convenient means to obtain the final group energy parameters of $E_{T}($ Group $)$ and $E_{D}($ Group $)$ is by using Eqs. (15.165-15.166) (Eqs. (15.183-15.184)) with $f_{1}=3 / 2$ and $c_{4}$ and $c_{5}$ multiplied by $3 / 2$.

The symbols of the functional groups of organic and related ions are given in Table 15.375. The geometrical (Eqs. (15.115.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters are given in Tables $15.376,15.377$, and 15.378 , respectively. Due to its charge, the bond angles of the organic and related ions that minimize the total energy are those that maximize the separation of the groups. For ions having three bonds to the central atom, the angles are $120^{\circ}$, and ions having four bonds are tetrahedral. The color scale, charge-density of exemplary organic ion, protonated lysine, comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.64.

Figure 15.64. Color scale, charge-density of protonated lysine ion showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei.

## MONOSACCHARIDES OF DNA AND RNA

The simple sugar moiety of DNA and RNA comprises the alpha forms of 2-deoxy-D-ribose and D-ribose, respectively. The sugars comprise the alkyl $\mathrm{CH}_{2}, \mathrm{CH}$, and $\mathrm{C}-\mathrm{C}$ functional groups and the alkyl alcohol $\mathrm{C}-\mathrm{O}$ and OH functional groups given in the Alcohols section. In addition, the alpha form of the sugars comprise the $C-O$ ether functional group given in the Ethers section, and the open-chain forms further comprise the carbon to carbonyl $C-C$, the methylyne carbon of the aldehyde carbonyl CH , and the aldehyde carbonyl $C=O$ functional groups given in the Aldehydes section. The total energy of each sugar given in Tables 15.379-15.382 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) corresponding to the functional-group composition wherein the group identity and energy $E_{D}$ (Group) are given in each table. The color scale, chargedensity of the monosaccharides, each comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figure 15.65.

Figure 15.65. ## NUCLEOTIDE BONDS OF DNA AND RNA

DNA and RNA comprise a backbone of alpha-2-deoxy-D-ribose and alpha-D-ribose, respectively, with a charged phosphate moiety at the 3 ' and $5^{\prime}$ ' positions of two consecutive ribose units in the chain and a base bound at the 1 ' position wherein the ribose $H$ of each of the corresponding $3^{\prime}$ or $5^{\prime} O-H$ and $1^{\prime} C-H$ bonds is replaced by $P$ and the base $N$, respectively. For the base, the $H$ of the $N-H$ at the pyrimidine 1 position or the purine 9 position is replaced by the sugar $C$. The basic repeating unit of DNA or RNA is a nucleotide that comprises a monosaccharide, a phosphate moiety and a base. The structure of the nucleotide bond is shown in Figure 15.66 with the designation of the corresponding atoms. The phosphate moiety comprises the $P=O, P-O$, and $C-O$ functional groups given in the Phosphates section as well as the $P-O^{-}$group given in the Organic and Related Ions section. The nucleoside bond (sugar C to base N ) comprises the tertiary amine $C-N$ functional group given in the corresponding section. The bases, adenine, guanine, thymine, and cytosine are equivalent to those given in the corresponding sections. The symbols of the functional groups of the nucleotide bond are given in Table 15.383. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters are given in Tables 15.384, 15.385, and 15.386, respectively. The functional group composition and the corresponding energy $E_{D}($ Group $)$ of each group of the nucleotide bond of DNA and RNA are given in Table 15.387. The bond angle parameters of the nucleoside bond determined using Eqs. (15.88-15.117) are given in Table 15.388. The color scale rendering of the charge-density of the exemplary tetra-nucleotide, (deoxy)adenosine 3 '-monophosphate- $5^{\prime}$ '-(deoxy)thymidine 3'-monophosphate-5'-(deoxy)guanosine $3^{\prime}$-monophosphate-5'-(deoxy)cytidine monophosphate (ATGC) comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.67. Figure 15.68 shows the color scale rendering of the charge-density of the exemplary DNA fragment $\begin{gathered}\text { ACTGACTGACTG } \\ \text { TGACTGACTGAC }\end{gathered}$ wherein each complementary strand comprises a dodeca-nucleotide of the form (base (1)deoxyribose) monophosphate- ( base(2)-deoxyribose) monophosphate- with the phosphates bridging the 3 ' and 5' ribose carbons with the opposite order for the complementary stands. Figure 15.68 shows the color scale rendering of the chargedensity of an exemplary double-stranded DNA helix.

Figure 15.66. Designation of the atoms of the nucleotide bond.

## AMINO ACIDS ( $\mathrm{H}_{2} \mathrm{~N}-\mathrm{CH}(\mathrm{R})-\mathrm{COOH}$ )

The amino acids, $\mathrm{H}_{2} \mathrm{NCH}(\mathrm{R}) \mathrm{COOH}$, each have a primary amine moiety comprised of $\mathrm{NH}_{2}$ and $\mathrm{C}-\mathrm{N}$ functional groups, an alkyl carboxylic acid moiety comprised of a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. The carboxylic acid moiety further comprises a $C-O H$ moiety that comprises $C-O$ and OH functional groups. The alpha carbon comprises a methylyne $(\mathrm{CH})$ functional group bound to a side chain $R$ group by an isopropyl $C-C$ bond functional group. These groups common to all amino acids are given in the Primary Amines section, the Carboxylic Acids section, and the Branched Alkanes section, respectively. The $R$ group is unique for each amino acid and determines its characteristic hydrophilic, hydrophobic, acidic, and basic properties. These characteristic functional groups are given in the prior organic functional group sections. The total energy of each amino acid given in Tables 15.389-15.408 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ corresponding to the functional-group composition of the amino acid wherein the group identity and energy $E_{D}($ Group $)$ are given in each table. The structure and the color scale, charge-density of the amino acids, each comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 15.70-15.89.

## ASPARTIC ACID

Figure 15.70. (A) Color scale, charge-density of aspartic acid showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure of aspartic acid.

## GLUTAMIC ACID

Figure 15.71. (A) Color scale, charge-density of glutamic acid showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure of glutamic acid.

## POLYPEPTIDES ( $-[H N-C H(R)-C(O)]_{n}-$ )

The amino acids can be polymerized by reaction of the OH group from the carboxylic acid moiety of one amino acid with $H$ from the alpha-carbon $\mathrm{NH}_{2}$ of another amino acid to form $\mathrm{H}_{2} \mathrm{O}$ and an amide bond as part of a polyamide chain of a polypeptide or protein. Each amide bond that forms by the condensation of two amino acids is called a peptide bond. It comprises a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. The peptide bond further comprises a $C-N H(R)$ moiety that comprises $N H$ and $C-N$ functional groups where $R$ is the characteristic side chain of each amino acid that is unchanged in terms of its functional group composition upon the formation of the peptide bond. From the N-Alkyl and N,N-Dialkyl-Amides section, the functional group composition and the corresponding energy $E_{D}($ Group $)$ of each group of the peptide bond is given in Table 15.409. The color scale, charge-density of the exemplary polypeptide, phenylalanine-leucine-glutamine-asparic acid (phe-leu-gln-asp) comprising the atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.90. The color scale, opaque view of the charge-density of the exemplary protein bovine pancreatic trypsin inhibitor (BPTI) is shown in Figure 15.91.

Figure 15.90. Color scale, charge-density of the polypeptide phenylalanine-leucine-glutamine-aspartic acid (phe-leu-glnasp) showing the orbitals of the atoms at their radii and the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond.

Figure 15.91. Color scale, opaque view of the charge-density of bovine pancreatic trypsin inhibitor (BPTI) protein created and modeled using Millsian 2.0. BPTI has been used as a medication administered by injection to reduce bleeding during complex surgery, such as heart and liver surgery. Its main effect is the inhibition of fibrinolysis, the process that leads to the breakdown of blood clots. The aim in its use is to decrease the need for blood transfusions during surgery, as well as end-organ damage due to hypotension (low blood pressure) as a result of marked blood loss. However, this drug was temporarily withdrawn worldwide in 2007 after studies suggested that its use increased the risk of complications or death. This protein is usually used as the benchmark for bimolecular modeling method and with accurate knowledge of its structure, it is possible to engineer it to avoid its prior side effects.

## Chapter 16

# APPLICATIONS: PHARMACEUTICALS, SPECIALTY MOLECULAR FUNCTIONAL GROUPS AND MOLECULES, DIPOLE MOMENTS AND INTERACTIONS 

## GENERAL CONSIDERATIONS OF THE BONDING IN PHARMACEUTICALS AND SPECIALTY MOLECULES

Pharmaceutical and specialty molecules comprising an arbitrary number of atoms can be solved using similar principles and procedures as those used to solve general organic molecules of arbitrary length and complexity. Pharmaceuticals and specialty molecules can be considered to be comprised of functional groups such as those of alkanes, branched alkanes, alkenes, branched alkenes, alkynes, alkyl fluorides, alkyl chlorides, alkyl bromides, alkyl iodides, alkene halides, primary alcohols, secondary alcohols, tertiary alcohols, ethers, primary amines, secondary amines, tertiary amines, aldehydes, ketones, carboxylic acids, carboxylic esters, amides, N -alkyl amides, $\mathrm{N}, \mathrm{N}$-dialkyl amides, ureas, acid halides, acid anhydrides, nitriles, thiols, sulfides, disulfides, sulfoxides, sulfones, sulfites, sulfates, nitro alkanes, nitrites, nitrates, conjugated polyenes, aromatics, heterocyclic aromatics, substituted aromatics, and others given in the Organic Molecular Functional Groups and Molecules section. The solutions of the functional groups can be conveniently obtained by using generalized forms of the geometrical and energy equations. The functional-group solutions can be made into a linear superposition and sum, respectively, to give the solution of any pharmaceutical or specialty molecule comprising these groups. The total bond energies of exemplary pharmaceutical or specialty molecules such as aspirin, RDX, and NaH are calculated using the functional group composition and the corresponding energies derived in the previous sections as well as those of any new component functional groups derived herein.

## ASPIRIN (ACETYLSALICYLIC ACID)

Aspirin comprises salicylic acid (ortho-hydroxybenzoic acid) with the $H$ of the phenolic $O H$ group replaced by an acetyl group. Thus, aspirin comprises the benzoic acid $C-C(O)-O H$ moiety that comprises $C=O$ and $O H$ functional groups that are the same as those of carboxylic acids given in the corresponding section. The single bond of aryl carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group given in the Benzoic Acid Compounds section. The aromatic $C \stackrel{3 e}{=} C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The phenolic ester $\mathrm{C}-\mathrm{O}$ functional group is equivalent to that given in the Phenol section. The acetyl $\mathrm{O}-\mathrm{C}(\mathrm{O})-\mathrm{CH}_{3}$ moiety comprises (i) $C=O$ and $C-C$ functional groups that are the same as those of carboxylic acids and esters given in the corresponding sections, (ii) a $\mathrm{CH}_{3}$ group that is equivalent to that of alkanes given in the corresponding sections, (iii) and a $C-O$ bridging the carbonyl carbon and the phenolic ester which is equivalent to that of esters given in the corresponding section.

The symbols of the functional groups of aspirin are given in Table 16.1.

The corresponding designations of aspirin are shown in Figure 16.1B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of aspirin are given in Tables 16.2, 16.3, and 16.4, respectively. The total energy of aspirin given in Table 16.5 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 16.4 corresponding to functional-group composition of the molecule. The bond angle parameters of aspirin determined using Eqs. (15.88-15.117) are given in Table 16.6. The color scale, translucent view of the charge density of aspirin comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 16.1A.

Figure 16.1. (A) Color scale, translucent view of the charge density of aspirin showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and designation of aspirin.

B

Table 16.1. The symbols of functional groups of aspirin.

| Functional Group | Group Symbol |
| :--- | :--- |
| CC (aromatic bond) | $\mathrm{C}=\mathrm{C}$ |
| CH (aromatic) | CH |
| Aryl $\mathrm{C}-\mathrm{C}(\mathrm{O})$ | $\mathrm{C}-\mathrm{C}(\mathrm{O})$ (i) |
| Alkyl $\mathrm{C}-\mathrm{C}(\mathrm{O})$ | $\mathrm{C}-\mathrm{C}(\mathrm{O})$ (ii) |
| $\mathrm{C=O}$ (aryl carboxylic acid) | $\mathrm{C}=\mathrm{O}$ |
| Aryl $(\mathrm{O}) \mathrm{C}-\mathrm{O}$ | $\mathrm{C}-\mathrm{O}$ (i) |
| Alkyl $(\mathrm{O}) \mathrm{C}-\mathrm{O}$ | $\mathrm{C}-\mathrm{O}$ (ii) |
| Aryl $\mathrm{C}-\mathrm{O}$ | $\mathrm{C}-\mathrm{O}$ (iii) |
| OH group | OH |
| $\mathrm{CH}_{3}$ group | $\mathrm{CH}_{3}$ |

## CYCLOTRIMETHYLENE-TRINITRAMINE ( $\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{~N}_{6} \mathrm{O}_{6}$ )

The compound cyclotrimethylene-trinitramine, commonly referred to as Cyclonite or by the code designation RDX, is a wellknown explosive. RDX comprises three methylene $\left(\mathrm{CH}_{2}\right)$ groups joined by six alkyl $\mathrm{C}-\mathrm{N}$ secondary amine functional groups given in the corresponding section. Each of the three $N$ 's of the six-membered ring shown in Figure 16.2B is bonded to a $\mathrm{NO}_{2}$ functional group given in the Nitroalkanes section by a $N-N$ functional group. The latter requires hybridization of the nitrogen atoms in order to match the energies of the bridged groups.

Similar to the case of carbon, silicon, and aluminum, the bonding in the nitrogen of the $N-N$ functional group involves four $s p^{3}$ hybridized orbitals formed from the outer $2 p$ and $2 s$ shells. In RDX, bonds form between two $N 2 s p^{3}$ HOs ( $N-N$ functional group), between a $N 2 s p^{3} \mathrm{HO}$ and a $C 2 s p^{3} \mathrm{HO}\left(C-N\right.$ functional group), and between a $N 2 s p^{3} \mathrm{HO}$ and a $O 2 p \mathrm{AO}$ (each $\mathrm{N}-\mathrm{O}$ bond of the $\mathrm{NO}_{2}$ functional group). The geometrical and energy equations of the $N-N$ functional group are given in the Derivation of the General Geometrical and Energy Equations of Organic Chemistry section wherein the energy is matched to $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)).

The $2 s p^{3}$ hybridized orbital arrangement after Eq. (13.422) is:

\[

\]

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the five electrons. The sum $E_{T}\left(N, 2 s p^{3}\right)$ of experimental energies [15] of $N, N^{+}, N^{2+}, N^{3+}$, and $N^{4+}$ is:

$$
\begin{align*}
E_{T}\left(N, 2 s p^{3}\right) & =-\binom{97.8902 \mathrm{eV}+77.4735 \mathrm{eV}+47.44924 \mathrm{eV}}{+29.6013 \mathrm{eV}+14.53414 \mathrm{eV}}  \tag{16.2}\\
& =-266.94838 \mathrm{eV}
\end{align*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{2 s p^{3}}$ of the $N 2 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{2 s p^{3}}=\sum_{n=2}^{6} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 266.94838 \mathrm{eV})}=\frac{15 e^{2}}{8 \pi \varepsilon_{0}(e 266.94838 \mathrm{eV})}=0.76452 a_{0} \tag{16.3}
\end{equation*}
$$

where $Z=7$ for nitrogen. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(N, 2 s p^{3}\right)$ of the outer electron of the $N 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(N, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{2 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.76452 a_{0}}=-17.79656 \mathrm{eV} \tag{16.4}
\end{equation*}
$$

In RDX, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $N$ HO has an energy of $E\left(N, 2 s p^{3}\right)=-17.79656 \mathrm{eV}$ (Eq. (16.4)). To meet the equipotential, minimum-energy condition of the union of the $N 2 s p^{3}$ and $C 2 s p^{3} \mathrm{HOs}, C_{2}=1$ in Eqs. (15.2-15.5), (15.51), and (15.61) for the $N-N$-bond MO, and $c_{2}$ given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } N_{b} 2 s p^{3} \mathrm{HO} \text { to } N_{a} 2 s p^{3} \mathrm{HO}\right)=\frac{E\left(C, 2 s p^{3}\right)}{E\left(N, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-14.63489 \mathrm{eV}}{-17.79656 \mathrm{eV}}(0.91771)=0.75468 \tag{16.5}
\end{equation*}
$$

The energy of the $N-N$-bond MO is the sum of the component energies of the $H_{2}$-type ellipsoidal MO given in Eq. (15.51). Since the energy of the MO is matched to that of the $C 2 s p^{3} \mathrm{HO}, E(A O / H O)$ in Eqs. (15.51) and (15.61) is: $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ given by Eq. (15.25) and $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ is 0 eV .

The symbols of the functional groups of RDX are given in Table 16.7. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of RDX are given in Tables 16.8, 16.9 , and 16.10 , respectively. The total energy of RDX given in Table 16.11 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 16.10 corresponding to functional-group composition of the molecule. The bond angle parameters of RDX determined using Eqs. (15.88-15.117) are given in Table 16.12. The color scale charge density of RDX comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 16.2A.

Figure 16.2. (A) Color scale charge density of RDX showing the outer orbitals of the atoms at their radii and the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond. (B) Chemical structure and atom designation of RDX.

## SODIUM HYDRIDE MOLECULE ( NaH )

Alkali hydride molecules each comprising an alkali metal atom and a hydrogen atom can be solved using similar principles and procedures as those used to solve organic molecules. The solutions of these molecules can be conveniently obtained by using generalized forms of the force balance equation given in the Force Balance of the $\sigma \mathrm{MO}$ of the Carbon Nitride Radical section and the geometrical and energy equations given in the Derivation of the General Geometrical and Energy Equations of Organic Chemistry section.

The bonding in the sodium atom involves the outer $3 s$ atomic orbital (AO), and the $N a-H$ bond forms between the $N a 3 s \mathrm{AO}$ and the $H 1 s \mathrm{AO}$. The energy of the reactive outer electron of the sodium atom is significantly less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.276). Consequently, the outer electron comprising the $N a 3 s \mathrm{AO}$ and the $H 1 s$ AO form a $\sigma-\mathrm{MO}$, and the inner AOs of $N a$ remain unaltered. The MO semimajor axis of molecular sodium hydride is determined from the force balance equation of the centrifugal, Coulombic, and magnetic forces as given in the Polyatomic Molecular Ions and Molecules section and the More Polyatomic Molecules and Hydrocarbons section. Then, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) wherein the distance from the origin of the $H_{2}$-type-ellipsoidal-MO to each focus $c^{\prime}$, the internuclear distance $2 c^{\prime}$, and the length of the semiminor axis of the prolate spheroidal $H_{2}$-type MO $b=c$ are solved from the semimajor axis $a$.

The force balance of the centrifugal force equated to the Coulombic and magnetic forces is solved for the length of the semimajor axis. The Coulombic force on the pairing electron of the MO is:

$$
\begin{equation*}
\mathbf{F}_{\text {Coulomb }}=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D \mathbf{i}_{\xi} \tag{16.6}
\end{equation*}
$$

The spin pairing force is

$$
\begin{equation*}
\mathbf{F}_{\text {spin-pairing }}=\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{16.7}
\end{equation*}
$$

The diamagnetic force is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO1 }}=-\frac{n_{e} \hbar^{2}}{4 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{16.8}
\end{equation*}
$$

where $n_{e}$ is the total number of electrons that interact with the binding $\sigma$-MO electron. The diamagnetic force $\mathbf{F}_{\text {diamagneticMOz }}$ on the pairing electron of the $\sigma \mathrm{MO}$ is given by the sum of the contributions over the components of angular momentum:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO2 }}=-\sum_{i, j} \frac{\left|L_{i}\right| \hbar}{Z_{j} 2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{16.9}
\end{equation*}
$$

where $|L|$ is the magnitude of the angular momentum of each atom at a focus that is the source of the diamagnetism at the $\sigma$ MO. The centrifugal force is:

$$
\begin{equation*}
\mathbf{F}_{\text {centrifugalMO }}=-\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{16.10}
\end{equation*}
$$

The force balance equation for the $\sigma$-MO of the $N a-H$-bond MO with $n_{e}=2$ and $|L|=\left(2+\sqrt{\frac{3}{4}}\right) \hbar$ is:

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(\frac{2}{2}+\frac{2}{Z}+\frac{\sqrt{\frac{3}{4}}}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{16.11}\\
& a=\left(2+\frac{2}{Z}+\frac{\sqrt{\frac{3}{4}}}{Z}\right) a_{0} \tag{16.12}
\end{align*}
$$

With $Z=11$, the semimajor axis of the $N a-H$-bond MO is:

$$
\begin{equation*}
a=2.26055 a_{0} \tag{16.13}
\end{equation*}
$$

Using the semimajor axis, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in the Organic Molecular Functional Groups and Molecules section. For the $\mathrm{Na}-\mathrm{H}$-bond MO of the $\mathrm{NaH}, c_{1}=1, c_{2}=1$ and $C_{2}=1$ in both the geometry relationships (Eqs. (15.2-15.5)) and the energy equation (Eq. (15.61)). In NaH the molecule, the Na 3 s AO has an energy of $E(N a 3 s)=-5.139076 \mathrm{eV}$ [15] and the $H$ AO has an energy of $E(H)=-13.59844 \mathrm{eV}$ [15]. To meet the equipotential condition of the union of the Na3s AO and the H1s $\mathrm{AO}, c_{2}$ and $C_{2}$ of Eqs. (15.2-15.5) and Eq. (15.61) for the $N a-H$-bond MO given by Eq. (15.77) is:

$$
\begin{equation*}
C_{2}(N a 3 s A O \text { to } H 1 s A O)=c_{2}(N a 3 s A O \text { to } H 1 s A O)=\frac{-5.139076 \mathrm{eV}}{-13.59844 \mathrm{eV}}=0.37792 \tag{16.14}
\end{equation*}
$$

The energy of the MO is matched to that of the $N a 2 p \mathrm{AO}$ with which it intersects such that $E(A O / H O)$ is $E(N a 2 p)=-47.2864 \mathrm{eV}$ [15]; thus, $E_{\text {initial }}\left(c_{4} A O / \mathrm{HO}\right)(\mathrm{eV})$ is given by the sum of $E(N a 2 p)=-47.2864 \mathrm{eV}$ and $E(N a 3 s)=-5.139076 \mathrm{eV}$.

The symbol of the functional group of molecular NaH is given in Table 16.13. The geometrical (Eqs. (15.1-15.5) and (16.11-16.14)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.61-15.65) and (16.13-16.14)) parameters of molecular NaH are given in Tables 16.14, 16.15, and 16.16, respectively. The color scale, translucent view of the charge-densities of molecular NaH comprising the concentric shells of the inner AOs of the Na atom and an outer MO formed from the outer Na 3 s AO and the $H 1 s \mathrm{AO}$ are shown in Figure 16.3.

Figure 16.3. Color scale, translucent view of the charge-densities of molecular NaH showing the inner orbitals of the Na atom at their radii, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO formed from the outer Na3s AO and the $H 1 s \mathrm{AO} H$, and the hydrogen nucleus (red, not to scale).

## BOND AND DIPOLE MOMENTS

The bond moment of a functional group may be calculated by considering the charge donation between atoms of the functional group. Since the potential of an MO is that of a point charge at infinity (Eq. (11.36)), an asymmetry in the distribution of charge between nonequivalent HOs or AOs of the MO occurs to maintain an energy match of the MO with the bridged orbitals. The charge must redistribute between the spherical orbitals to achieve a corresponding current-density that maintains constant current at the equivalent-energy condition according to the energy-matching factor such as $c_{2}$ or $C_{2}$ of Eqs. (15.51) and (15.61). Since the orbital energy and radius are reciprocally related, the contribution scales as the square of the ratio (over unity) of the energy of the resultant net positively-charged orbital and the initial matched energy of the resultant net negatively-charged orbital of the bond multiplied by the energy-matching factor (e.g. $c_{2}$ or $C_{2}$ ). The partial charges on the HOs or AOs corresponding to the charge contribution are equivalent to point charges centered on the nuclei. Due to symmetry, the bond moment $\mu$ of each functional group is along the internuclear axis and is calculated from the partial charges at the separation distance, the internuclear distance.

Using the reciprocal relationship between the orbital energies and radii, the dependence of the orbital area on the radius squared, and the relationship of the partial charge $q$ to the areas with energy matching for each electron of the MO, the bond moment $\mu$ along the internuclear axis of $A-B$ wherein $A$ is the net positively-charged atom is given by:

$$
\begin{equation*}
\mu=q d=n_{1} c e\left(1-\left(\frac{E_{A}(\text { valence })}{E_{B}(\text { valence })}\right)^{2}\right) 2 c^{\prime} \tag{16.15}
\end{equation*}
$$

wherein $n_{1}$ is the number of equivalent bonds of the MO, $c$ is energy-matching factor such as $c_{1}, c_{2}, C_{1}$, or $C_{2}$ of Eqs. (15.51) and (15.61) where $c_{1}$ and $C_{2}$ may correspond to both electrons of a MO localized on one AO or HO such as when the magnitude of the valence or Coulombic energy of the AO or HO is less than that of $E_{\text {Coulomb }}(H)=-13.605804 \mathrm{eV}$ or when the orbital may contain paired or shared electrons in a linear combination with the partner orbital, and $d$ is the charge-separation distance, the internuclear distance $2 c^{\prime} . E_{B}$ (valence) is the initial matched energy of the resultant net negatively-charged orbital of the bond that is further lowered by bonding (Eqs. (15.32) and (15.16)) to atom $A$ having an energy $E_{A}$ (valence). Typically, $E_{B}$ (valence) of a carbon-heteroatom bond is -14.63489 eV , the initial $C 2 s p^{3} \mathrm{HO}$ (Eq. (15.25)) energy to which the heteroatom is energy matched. Functional group bond moments determined using Eq. (16.15) are given in Table 16.17.

Table 16.17. The bond moments of functional groups compared to experimental values [22-87] wherein the parameters correspond to those given previously except as indicated.

$\mathrm{m}_{c_{2}}$ from Eq. (15.77) using $E(F)=-17.42282 \mathrm{eV}$ and $E\left(B_{B-F b o r a n e}, 2 s p^{3}\right)=-14.88734 \mathrm{eV}$ (Eq. (22.61)).

The dipole moment of a given molecule is then given by the vector sum of the bond moments in the molecule. Thus, the dipole moment is given by taking into account the magnitude and direction of the bond moment of each functional group wherein the functional group bond moment stays constant from molecule to molecule and is in the vector direction of the internuclear axis. The dipole moments of water and ammonia to compare to the experimental values are given from the corresponding moments in Table 16.17. The calculated dipole moment of $\mathrm{H}_{2} \mathrm{O}$ is:

$$
\begin{equation*}
\mu_{\mathrm{H}_{2} \mathrm{O}}=2(1.51) \cos \left(\frac{106^{\circ}}{2}\right)=1.8128 D \tag{16.16}
\end{equation*}
$$

where the angle between the $\mathrm{O}-\mathrm{H}$ bond is $106^{\circ}$ given by Eq. (13.242). The experimental dipole moment of $\mathrm{H}_{2} \mathrm{O}$ is [23] :

$$
\begin{equation*}
\mu_{H_{2} \mathrm{O}}=1.8546 \mathrm{D} \tag{16.17}
\end{equation*}
$$

The calculated dipole moment of $\mathrm{NH}_{3}$ is:

$$
\begin{equation*}
\mu_{\mathrm{NH}_{3}}=3(1.30) \cos \left(68^{\circ}\right)=1.467 \mathrm{D} \tag{16.18}
\end{equation*}
$$

where the angle between each $N-H$ bond and the z-axis is $68^{\circ}$ given by Eq. (13.417). The experimental dipole moment of $\mathrm{NH}_{3}$ is [23]:

$$
\begin{equation*}
\mu_{N H_{3}}=1.4718 D \tag{16.19}
\end{equation*}
$$

The charge distributions of the functional groups given in Table 16.17 facilitate the rendering of the charge distribution of molecules of unlimited complexity comprised of these functional groups. What was previously impossible to achieve using supercomputers can be readily accomplished on a personal computer (PC). The rendering of the true charge densities of the exemplary proteins insulin and lysozyme are shown in color scale, opaque view in Figures 16.4 and 16.5, respectively. The color scale, opaque view of the charge density of an exemplary double-stranded RNA helix is shown in Figure 16.6.

Figure 16.4. Color scale, opaque view of the charge density of insulin created and modeled using Millsian 2.0 on a PC.

Figure 16.5. Color scale, opaque view of the charge density of lysozyme created and modeled using Millsian 2.0 on a PC.

Figure 16.6. Color scale, opaque view of the charge density of a double-stranded DNA helix created and modeled using Millsian 2.0 on a PC.

## NATURE OF THE DIPOLE BOND: DIPOLE-DIPOLE, HYDROGEN, AND VAN DER WAALS BONDING

The boundless number and length of permutations of the functional groups can form a correspondingly infinite number of molecules. The intermolecular forces instill upon molecules their inherent properties such as state-being solid, liquid, or gas, the temperatures at which phase transitions occur, and the energy content change required to change the state. However, the types of bonding are relatively few even though the breadth of molecular compositions is infinite. Since all molecules comprise nuclei that behave on the scale of molecules as electrostatic point charges, and electrically charged electrons exist as charge and current densities that obey Maxwell's equations, the binding is determined by electrical and electrodynamics forces. These typically dominate over any magnetic forces since the latter is a relativistic effect of the former and is thus negligible as the norm. Thus, essentially all molecular bonding is Coulombic in nature. The extreme case involves ions, and ionic bonding between charged functional groups of molecules obeys the same physical principles as inorganic ions as given in the Nature of the Solid Ionic Bond of Alkali Hydrides and Halides section. Similarly, the charge-density distributions of negatively-charged electrons relative to the positively-charged nuclei of neutral molecules gives rise to Coulombic-based bonding that can be grouped into two main categories, bonding that comprises permanent dipole-dipole interactions further including an extreme case, hydrogen bonding, and bonding regarding reversible mutually induced dipole fields in near-neighbor molecules called van der Waals bonding.

The H bond is exemplary of the extreme of dipole-dipole interactions as the source of bond energy and rises from the extremely high dipole moments of $H$ bound to $F, O$, or $N$ as shown in the Bond and Dipole Moments section. The bond energies of these types of bonds are large due to the very high Coulombic energy associated with the dipole-dipole interaction between H -bonded molecules compared to those having much lower dipole moments. Still H-bond energies are typically small by the standards of covalent bonds. The differences are also reflected in the relative bond lengths. In water for example, the $O-H$ bond distance and energy are $2 c^{\prime}=0.970 \pm .005 \AA$ (Eq. (13.186)) and $E_{D}\left(H^{16} \mathrm{OH}\right)=5.1059 \mathrm{eV}$ (Eq. (13.222), respectively; whereas, those of the hydrogen bond of water are $2 c_{o \ldots H}^{\prime}=1.78 \AA$ (Eq. (16.27) and $E_{\text {vapor, } 0^{\circ} \mathrm{C}}=0.233 \mathrm{eV} / \mathrm{H}$ - bond (Eq. (16.57)), respectively. On the other end of the spectrum, van der Waals bonds are also Coulombic in nature and are between dipoles. However, the dipoles are mutually induced rather than permanent, and the mutual induction is typically small. Thus, the bond distances are on the order of angstroms and the energies in the 10 's of meV's range. The bonding between molecules gives rise to condensed matter, and the classical theory of condensed matter based on these forms of bonding is treated next.

## CONDENSED MATTER PHYSICS

Condensed matter comprises liquids and solids of atoms and molecules. It is shown infra that the geometrical parameters, energies, and properties of the latter can be solved using the same equations as those used to solved the geometrical parameters and component energies of the individual molecules as given in the Organic Molecular Functional Groups and Molecules section.

The structure and properties of liquids can be solved by first solving the unit cell of the corresponding condensed solid. The unit cell may be solved by first determining the packing that minimizes the lattice energy. In nature, there are a small, finite number of packing arrangements. The particular arrangement relates to the most efficient one giving the most objects packed into a given space with the size and shape limitations. The water molecule, for example, is small compared to the unit cell of ice; so, it will naturally assume a tetrahedral structure and hexagonal packing given the geometry of its electric dipoles with a partial positive on the $H$ 's and partial negative on the $O$. In general, a reiterative algorithm is used that optimizes the packing of the molecules and tests that packing against the unit cell parameters and lattice energy until an optimum is found. The lattice parameters can be verified by X-ray crystallography and neutron diffraction. The lattice energy can be measured using calorimetry; so, the model can be directly tested.

Bonding in neutral condensed solids and liquids arises from interactions between molecules wherein the molecules of the lattice have multipoles that give rise to corresponding Coulombic or magnetic interactions. Typically, the multipoles are electric or magnetic dipoles. Consider the former case. Since the separated partial charges that give rise to bond moments are equivalent to point charges centered on the bond nuclei as given in the Bond and Dipole Moments section, the maximum interaction energy between interacting species can be calculated using Coulomb's law with the corresponding partial monopole charges and separation distance. The energy from the interaction of the partial charges increases as the separation decreases, but concomitantly, the energy of a bond that may form between the interacting species increases as well. The equilibrium separation distance corresponds to the occurrence of the balance between the Coulombic potential energy of the interacting atoms and the energy of the bond whose formation involves the interacting atoms. Thus, the balance is at the energy threshold for the formation of a nascent bond that would replace the interacting partial charges while also destabilizing the standard bonds of the interacting molecules. Then, an optimal lattice structure corresponds to an energy minimum with an associated energy. The minimum energy structure corresponds to the highest density of interacting dipoles in their minimum energy state. A convenient method to calculate the lattice energy is to determine the electric or magnetic field in the material having an electric or magnetic polarization density, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic or magnetostatic form of Gauss' or Amperes' equation, respectively.

Once the $a, b$, and $c$ parameters of the unit cell are solved from the energy (force) balance between the electric monopoles and the nascent bond energy, the unit cell is determined. Then, the unit cell can be proliferated to arbitrary scale to render the solid. Typically, only one lattice parameter needs to be determined since the additional distances can be determined
from geometrical relations based on the unit cell structure. The lattice energy may be calculated from the potential between dipoles using the cell parameters. The dielectric constant and other properties may also be calculated using Maxwell's equations and other first principles.

The structures of liquids can be modeled as linear combinations of unit cells comprising perturbations of the solid unit cell. In one approach, increasing disorder is added to the solid structure in the transition from solid to liquid to gas. Complete disorder or statistical gas behavior applies in the ideal gas limit. Thus, liquid states may be modeled by adding more cells with increasing loss of order of the solid unit cell as the temperature of the liquid is increased. The disorder is due to population of translational, rotational, and vibrational levels to match the internal energy at a given temperature. Consider thermodynamics. In principle, it is possible to classically calculate the fields over all space, the exact field interactions, and the position, trajectory, momentum, and energy of every particle of a material at each instance. Then, the material properties can be determined from these parameters. However, in practice, it is impossible computationally. For the same reason, simple underlying physical principles are applied to derive statistical properties for large ensembles of particles as given in the Statistical Mechanics section. The same statistical thermodynamic methods may be applied to modeling liquids and gases using the exact solutions of the individual molecules. Using the molecular geometrical parameters, charge distributions, and corresponding interactions as input, unit cells can be computed based on the solid unit cell. Working with increasing numbers of unit cells of increasing randomness and populating the unit cells based on appropriate statistical models such as Boltzmann statistics for increasing enthalpy input and temperature, accurate models of liquids are provided. The corresponding liquid properties can be solved from each liquid structure.

A preferred approach to solving the energy and geometric parameters of ice, considered next, is to solve the separation distance of the electric monopoles comprising a partial positive on each $H$ and a partial negative charge on each $O$ as the balance between the Coulombic attraction energy between the partial charges and the repulsion energy due to the formation of a nascent $H-O$ bond between the hydrogen-bonded atoms. The nascent bond substitutes for the hydrogen bond while also removing electron density and stability from the standard water molecule bonds. Thus, it offsets the Coulombic energy and establishes the equilibrium minimum approach distance of the interacting atoms of the water molecules. Then, using Gauss's law, the energy per water molecule is calculated as the dipole energy in the electric field of the lattice of electric dipoles.

## GEOMETRICAL PARAMETERS AND ENERGIES OF THE HYDROGEN BOND OF $H_{2} \mathrm{O}$ IN THE ICE PHASE

The extraordinary properties of water are determined by hydrogen $(\mathrm{H})$ bonds, designated by the dotted bond $O-H \cdots O$, each between a participating $H$ of one water molecule and an $O$ of another. The structure of each phase of water is then determined by the number of H bonds on average per water molecule. As shown in the Bond and Dipole Moments section, the $O-H$ bond has a bond moment $\mu$ of 1.51 D corresponding to a partial charge on each $H$ of $+0.323 e$ and a component of partial charge on each $O$ per bond moment of $-0.323 e$. The thermodynamic basis of the H bond is the minimization of the Coulombic energy between the $H$ and $O$ of the hydrogen bond, limited by the formation of a nascent bond between these atoms that destabilizes the initial $O-H$ bond. The sum of the torques and forces are zero at force balance to achieve a hexagonal crystal structure that is an energy minimum. The maximum electrostatic energy of the partial charges is calculated for the components along the H bond axis. This energy is balanced by the total energy of the nascent bond that can form between the $H \cdots O$ atoms of the H bond. The bond length of the H bond, the internuclear distance between the $H$ and $O$ of the $H \cdots O$ bond, is calculated by a similar method as that used to determine the bond angle given in the Bond Angle of $\mathrm{H}_{2} \mathrm{O}$ section.

The $\mathrm{H}_{2} \mathrm{O}$ MO comprises a linear combination of two $\mathrm{O}-H$-bond MOs. Each $\mathrm{O}-H$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and the $O 2 p_{z}$ AO or the $O 2 p_{y}$ AO with a relative $H$ partial orbital contribution to the MO of 0.75 ; otherwise, the $O 2 p$ orbitals are the same as those of the oxygen atom. The solution of the geometrical parameters and component energies are given in the Water Molecule $\left(\mathrm{H}_{2} \mathrm{O}\right)$ section and the color scale charge density of the $\mathrm{H}_{2} \mathrm{O} \mathrm{MO}$ is shown in Figure 16.7.

Figure 16.7. $\mathrm{H}_{2} \mathrm{O}$ MO comprising the linear combination of two $O-H$-bond MOs. Each $O-H$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and the $O 2 p_{z} \mathrm{AO}$ or the $O 2 p_{y} \mathrm{AO}$ with a relative charge-density of 0.75 to 1.25 ; otherwise, the $O 2 p$ orbitals are the same as those of the oxygen atom. The internuclear axis of one $O-H$ bond is perpendicular to the bonding $p_{y}$ orbital, and the internuclear axis of the other $O-H$ bond is perpendicular to the bonding $p_{z}$ orbital. (A) Color scale, translucent view of the charge-density of the $\mathrm{H}_{2} \mathrm{O} \mathrm{MO}$ from the top. For each $\mathrm{O}-\mathrm{H}$ bond, the ellipsoidal surface of each $H_{2}$-type ellipsoidal MO transitions to the $O 2 p$ AO. The $O 2 p$ shell, the $O 2 s$ shell, the $O 1 s$ shell, and the nuclei (red, not to scale) are shown. (B) Cut-away view showing the innermost $O 1 s$ shell, and moving radially, the $O 2 s$ shell, the $O 2 p$ shell, and the $H_{2}$-type ellipsoidal MO that transitions to the $O 2 p$ AO for each $O-H$ bond. Bisector current not shown.

Rather than consider the possible bond between the two H atoms of the $\mathrm{O}-H$ bonds in the determination of the bond angle, consider that the hydrogen bond may achieve a partial bond order or partial three-centered $O-H-O$ bond as given in the Bridging Bonds of Organoaluminum Hydrides ( $A l-H-A l$ and $A l-C-A l$ ) and Bridging Bonds of Boranes ( $B-H-B$ and $B-B-B$ ) sections, and the H can become mobile between water molecules corresponding to H exchange. Such exchange of $O \cdots H-O$ to $O-H \cdots O$ bonding would decrease the initial $O-H$-bond strength since electron density would be shifted from the $O-H$ bonds to the $O \cdots H$ bond. Concomitantly, the Coulombic energy of the H bond would be eliminated. Thus, the equilibrium distance $r_{e}$ or internuclear bond distance of $O \cdots H$ designated as $2 c_{O \cdots H}^{\prime}=r_{e}$ is determined by the condition that the total energy of the nascent $H_{2}$-type ellipsoidal MO formed from the atoms of the $O \cdots H$ bond is equal to the maximum Coulombic energy between the partial charges of the $H$ and $O$ atoms of the H bond.

The $O-H$ bond moments superimpose at the central $O$. The minimum energy corresponds to the maximum separation of the $\delta^{-}$of each bond moment on the $O$ atom that occurs in space and time with $\pi$ phase. The corresponding distance is the hypotenuse of the right triangle having the distance $2 c_{O \cdots H}^{\prime}$ between the $H$ and $O$ nuclei of the $H \cdots O$ bond as one side and the radius of the oxygen atom, $r_{O 2 p}=a_{0}$ (Eq. (10.162)), as the other. Then, the maximum Coulomb energy $E_{\text {Coulomb }}(H-b o n d)$ between the atoms of the $O \cdots H$ bond due to the two separated $\delta^{-}$'s on the oxygen atom with the $\delta^{+}$centered on the nucleus of hydrogen is:

$$
\begin{equation*}
E_{\text {Coulomb }}(H-\text { bond })=\frac{-2 \delta^{2} e^{2}}{4 \pi \varepsilon_{0} \sqrt{\left(2 c_{O \cdots H}^{\prime}\right)^{2}+\left(r_{O 2 p}\right)^{2}}} \tag{16.20}
\end{equation*}
$$

Since each H bond is between two $\mathrm{H}_{2} \mathrm{O}$ molecules and there are four H bonds per $\mathrm{H}_{2} \mathrm{O}$ molecule, the Coulomb energy per $\mathrm{H}_{2} \mathrm{O} \quad E_{\text {Coulomb }}\left(\mathrm{H}_{2} \mathrm{O}\right)$ is equivalent to two times $E_{\text {Coulomb }}(H$-bond $)$ (Eq. (16.20)):

$$
\begin{equation*}
E_{\text {Coulomb }}\left(\mathrm{H}_{2} \mathrm{O}\right)=\frac{-4 \delta^{2} e^{2}}{4 \pi \varepsilon_{0} \sqrt{\left(2 c_{O \ldots H}^{\prime}\right)^{2}+\left(r_{O 2 p}\right)^{2}}} \tag{16.21}
\end{equation*}
$$

Eq. (16.21) is the energy to be equated to that of the nascent covalent bonds involving the atoms of the H bonds of the water molecule. Using Eq. (15.3), the internuclear distance of this bond, $2 c_{o \ldots H}^{\prime}=r_{e}$, in terms of the corresponding semimajor axis $a_{O \ldots H}$ is:

$$
\begin{equation*}
2 c_{O \cdots H}^{\prime}=2 \sqrt{\frac{a_{o \ldots H} a_{0}}{2 C_{1} C_{2}}} \tag{16.22}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal MO $b=c$ is given by:

$$
\begin{equation*}
b_{O \ldots H}=\sqrt{\left(a_{O \ldots H}\right)^{2}-\left(c_{O \ldots H}^{\prime}\right)^{2}} \tag{16.23}
\end{equation*}
$$

And, the eccentricity, $e$, is:

$$
\begin{equation*}
e_{O \ldots H}=\frac{c_{O \ldots H}^{\prime}}{a_{O \cdots H}} \tag{16.24}
\end{equation*}
$$

The semimajor axis $a_{O \cdots H}$ of the $O \cdots H$ bond is determined using the general equation for determination of the bond angle between terminal atoms given by Eqs. (15.93) and (15.99) with Eqs. (15.46-15.47) except that the MO energy is matched to the Coulombic energy of the H bond (Eq. (16.21) with substitution of Eq. (15.3)) rather than being set equal to zero for zero interaction energy in the case of the bond-angle determination:
where $n_{1}$ is the number of equivalent bonds of the MO, $c_{1}$ is the fraction of the $H_{2}$-type ellipsoidal MO basis function, $c_{2}$ is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of each chemical bond, $C_{10}$ is the fraction of the $H_{2}$-type ellipsoidal MO basis function of the oscillatory transition state of a chemical bond of the group, and $C_{20}$ is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of the transition state of the chemical bond, $E_{T}(A O / H O)$ is the total energy comprising the difference of the energy $E(A O / H O)$ of at least one atomic or hybrid orbital to which the MO is energy matched and any energy component $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}(\mathrm{AO} / \mathrm{HO})$ due to the AO or HO's charge donation to the MO, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is the change in the energy of the AOs or HOs upon forming the bond, and $\mu$ is the reduced mass.

For the determination of the H -bond distance, the energy parameters are the same as those of water given in the Water Molecule $\left(\mathrm{H}_{2} \mathrm{O}\right)$ section except that any parameters due to matching AO's, $E_{T}(\mathrm{AO} / \mathrm{HO})$ and $E_{T}\left(\right.$ atom-atom, msp $\left.{ }^{3} . \mathrm{AO}\right)$, is zero since only the energies of the MO electrons to form the $O \cdots H$ MO are considered. The partial charge $\delta=q / e$ from Table 16.17 is 0.323 , and the reduced mass is $\mu=\frac{16}{17}$. The parameters are summarized in Table 16.18 and Eq. (16.26).

Table 16.18. The energy parameters $(\mathrm{eV})$ of the $O \cdots H$ functional group of the hydrogen bond of Type I ice.

| Parameters | $O \cdots H$ Group |
| :---: | :---: |
| $\delta$ | 0.323 |
| $n_{1}$ | 2 |
| $C_{1}$ | 0.75 |
| $C_{2}$ | 1 |
| $c_{1}$ | 0.75 |
| $c_{2}$ | 1 |
| $C_{10}$ | 1.5 |
| $C_{2}$ | 1 |
| $V_{e}(\mathrm{eV})$ | -20.30177 |
| $V_{p}(e V)$ | 16.15958 |
| $T(e V)$ | 2.38652 |
| $V_{m}(\mathrm{eV})$ | -1.19326 |
| $E($ Ао/но) $(\mathrm{eV})$ | 0 |
| $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}($ Ао/ $/ \mathrm{HO})(\mathrm{eV})$ | 0 |
| $E_{T}($ Ао/но) $(\mathrm{eV})$ | 0 |
| $E_{T}\left(\mathrm{H}_{2} \mathrm{MO}\right)(\mathrm{eV})$ | -2.94892 |
| $E_{T}\left(\right.$ atom -atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)(\mathrm{eV})$ | 0 |

| $E_{T}($ Group $)(\mathrm{eV})$ | -2.94054 |

Substitution of the parameters of Table 16.18, the internuclear distance $2 c_{O-H}^{\prime}$ given by Eq. (13.185), and $R$ given by Eq. (16.23) and (16.22) into Eq. (16.25) gives:

(16.26)

From the energy relationship given by Eq. (16.26) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $O \cdots H$ MO can be solved.

The most convenient way to solve Eq. (16.26) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a_{O \ldots H}=4.25343 a_{0}=2.25082 \times 10^{-10} \mathrm{~m} \tag{16.27}
\end{equation*}
$$

The component energy parameters at this condition are given in Table 16.18. Substitution of Eq. (16.27) into Eq. (16.22) gives

$$
\begin{equation*}
c_{O \ldots H}^{\prime}=1.68393 a_{0}=8.91097 \times 10^{-11} \mathrm{~m} \tag{16.28}
\end{equation*}
$$

and internuclear distance of the H bond:

$$
\begin{equation*}
2 c_{O \cdots H}^{\prime}=3.36786 a_{0}=1.78219 \times 10^{-10} m=1.78219 \AA \tag{16.29}
\end{equation*}
$$

The internuclear distance of the $O-H$ given by Eq. (13.185) is:

$$
\begin{equation*}
2 c^{\prime}=1.83601 a_{0}=9.71574 \times 10^{-11} \mathrm{~m} \tag{16.30}
\end{equation*}
$$

The internuclear distance $2 c_{O-H}^{\prime}$ of the $O-H$ bond added to $2 c_{O \ldots H}^{\prime}$ gives the internuclear distance $2 c_{O \ldots H O}^{\prime}$ between the oxygen atoms of the group $O-H \cdots O$ :

$$
\begin{equation*}
2 c_{o \cdots H O}^{\prime}=2 c_{O \cdots H}^{\prime}+2 c_{O-H}^{\prime} \tag{16.31}
\end{equation*}
$$

Substitution of $2 c_{O \cdots H}^{\prime}$ (Eq. (16.29)) and $2 c_{O-H}^{\prime}$ (Eq. (13.185)) into Eq. (16.31) gives the nearest-neighbor separation, the internuclear distance $2 c_{O \cdots H O}^{\prime}$ between the oxygen atoms of the $O-H \cdots O$ bond in Type I ice:

$$
\begin{equation*}
2 c_{O \ldots H O}^{\prime}=2 c_{O \ldots H}^{\prime}+2 c_{O-H}^{\prime}=1.78219 \times 10^{-10} m+9.71574 \times 10^{-11} \mathrm{~m}=2.75377 \times 10^{-10} \mathrm{~m}=2.75377 \AA \tag{16.32}
\end{equation*}
$$

The experimental oxygen nearest-neighbor separation distance $2 c_{o \ldots H O}^{\prime}$ is [88]:

$$
\begin{equation*}
2 c_{O \ldots H O}^{\prime}=2.75 \AA \tag{16.33}
\end{equation*}
$$

The experimental internuclear distance of the $\mathrm{O}-\mathrm{H}$ bond of $\mathrm{H}_{2} \mathrm{O}$ is [89]:

$$
\begin{equation*}
2 c^{\prime}=9.70 \pm .005 \times 10^{-11} \mathrm{~m} \tag{16.34}
\end{equation*}
$$

Using Eqs. (16.33) and (16.34), the experimental $H$ bond distance $2 c_{O \ldots H}^{\prime}$ in Type I ice is [88, 89]:

$$
\begin{equation*}
2 c_{O \ldots H}^{\prime}=1.78 \AA \tag{16.35}
\end{equation*}
$$

The other H-bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.27) and (16.28) into Eq. (16.23) gives:

$$
\begin{equation*}
b_{O \cdots H}=c_{O \cdots H}=3.90590 a_{0}=2.06691 \times 10^{-10} \mathrm{~m} \tag{16.36}
\end{equation*}
$$

Substitution of Eqs. (16.27) and (16.28) into Eq. (16.24) gives:

$$
\begin{equation*}
e_{O \cdots H}=0.39590 \tag{16.37}
\end{equation*}
$$

Since water is a hexagonal crystal system in common with the carbon allotrope diamond, the internuclear distance of the two terminal $O$ atoms of a set of three $H_{2} O$ 's corresponding to the hexagonal lattice parameter $a_{l}$ is calculated using the same approach as that given by Eqs. (17.1-17.3) using the law of cosines:

$$
\begin{equation*}
s_{1}{ }^{2}+s_{2}{ }^{2}-2 s_{1} s_{2} \operatorname{cosine} \theta=s_{3}{ }^{2} \tag{16.38}
\end{equation*}
$$

where $s_{3}=a_{l}$ is the hypotenuse of the isosceles triangle having equivalent sides of length equal to $2 c_{O \ldots H O}^{\prime}$. With the bond angle between three water molecules formed by the two corresponding H bonds given by $\theta_{\angle \mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{2} \mathrm{O}}=109.5^{\circ}$ [90] and $s_{1}=s_{2}=2 c_{O \ldots H O}^{\prime}$ given by Eq. (16.32), the distance between the oxygen atoms of the terminal water molecules along the hypotenuse, $s_{3}=2 c_{\mathrm{H}_{2} \mathrm{O}-\mathrm{H}_{2} \mathrm{O}}^{\prime}=a_{l}$, is:

$$
\begin{equation*}
a_{l}=2 c_{H_{2} O-H_{2} \mathrm{O}}^{\prime}=\sqrt{2\left(2 c_{O \ldots H O}^{\prime}\right)^{2}\left(1-\operatorname{cosine}\left(109.5^{\circ}\right)\right)}=\sqrt{2(2.75377 \AA)^{2}\left(1-\operatorname{cosine}\left(109.5^{\circ}\right)\right)}=4.49768 \AA \tag{16.39}
\end{equation*}
$$

Due to the tetrahedral structure shown in Figure 16.8, four water molecules form a pyramidal structure with a central $\mathrm{H}_{2} \mathrm{O}(1)$ at the apex designated as on the z-axis, and the three other water molecules, $\mathrm{H}_{2} \mathrm{O}(n) n=2,3,4$, form the base in the xy-plane. As further shown in Figure 16.8, a fifth $\mathrm{H}_{2} \mathrm{O}(5)$ is positioned a distance $2 c_{O \cdots H O}^{\prime}$ along the z-axis. Twice the height along the z-axis from the base of the pyramid to the fifth $\mathrm{H}_{2} \mathrm{O}$ comprises the Type I ice unit cell parameter $c$ which is determined next using Eqs. (13.412-13.417).

Since any two $O-H \cdots O$ bonds having the internuclear distance $2 c_{O \cdots H O}^{\prime}$ between the oxygen atoms of Type I ice form an isosceles triangle having the hypotenuse $a_{l}$ between the terminal oxygens, the distance $d_{\text {origin- } O}$ from the origin of the pyramidal base to the nucleus of a terminal oxygen atom is given by:

$$
\begin{equation*}
d_{\text {origin }-O}=\frac{a_{l}}{2 \sin 60^{\circ}} \tag{16.40}
\end{equation*}
$$

Substitution of Eq. (16.39) into Eq. (16.40) gives

$$
\begin{equation*}
d_{\text {origin }-O}=2.59674 a_{0} \tag{16.41}
\end{equation*}
$$

The height $d_{\text {height }}$ along the z-axis of the pyramid from the origin to the O nucleus of $\mathrm{H}_{2} \mathrm{O}(1)$ is given by:

$$
\begin{equation*}
d_{\text {height }}=\sqrt{\left(2 c_{O \ldots H O}^{\prime}\right)^{2}-\left(d_{\text {origin }-O}\right)^{2}} \tag{16.42}
\end{equation*}
$$

Substitution of Eqs. (16.32) and (16.41) into Eq. (16.42) gives:

$$
\begin{equation*}
d_{\text {height }}=0.91662 a_{0} \tag{16.43}
\end{equation*}
$$

The angle $\theta_{v}$ of each $O-H \cdots O$ bond from the z-axis is given by:

$$
\begin{equation*}
\theta_{v}=\tan ^{-1}\left(\frac{d_{\text {origin }-O}}{d_{\text {height }}}\right) \tag{16.44}
\end{equation*}
$$

Substitution of Eqs. (16.41) and (16.43) into Eq. (16.44) gives:

$$
\begin{equation*}
\theta_{v}=70.56^{\circ} \tag{16.45}
\end{equation*}
$$

Using Eqs. (16.32) and (16.43), the hexagonal lattice parameter $c_{l}$ for Type I ice given by twice the height along the z-axis from the base of the pyramid to the fifth water, $\mathrm{H}_{2} \mathrm{O}(5)$, is

$$
\begin{equation*}
c_{l}=2\left(2 c_{O \ldots H O}^{\prime}+d_{\text {height }}\right)=2(2.75377 \AA+0.91662 \AA)=7.34077 \AA \tag{16.46}
\end{equation*}
$$

The experimental lattice parameters $a_{l}$ and $c_{l}$ for Type I ice are [90, 91]:

$$
\begin{align*}
& a_{l}=4.49 \AA  \tag{16.47}\\
& a_{l}=4.5212 \AA
\end{align*}
$$

and [91, 92] :

$$
\begin{align*}
& c_{l}=7.31 A \\
& c_{l}=7.3666 A \tag{16.48}
\end{align*}
$$

The tetrahedral unit cell and the ideal hexagonal lattice structure of Type I ice are shown in Figures 16.8-16.10, using the color scale charge density of each water molecule.

Figure 16.8. Tetrahedral unit cell structure of Type I ice using the transparent color scale charge density of each $\mathrm{H}_{2} \mathrm{O}$ MO comprising the linear combination of two $O-H$-bond MOs. (A) Each dipole-dipole bond that is Coulombic in nature is depicted by connecting sticks. (B) Bond representation removed.

Figure 16.9. C -axis view of the ideal hexagonal lattice structure of Type I ice using the opaque color scale charge density of each $\mathrm{H}_{2} \mathrm{O}$ MO comprising the linear combination of two $\mathrm{O}-\mathrm{H}$-bond MOs. Each dipole-dipole bond that is Coulombic in nature is depicted by connecting sticks.

Figure 16.10. An off-angle view of the ideal hexagonal lattice structure of Type I ice using the opaque color scale charge density of each $\mathrm{H}_{2} \mathrm{O}$ MO comprising the linear combination of two $\mathrm{O}-\mathrm{H}$-bond MOs. Each dipole-dipole bond that is Coulombic in nature is depicted by connecting sticks.

A convenient method to calculate the lattice energy is to determine the electric field in ice having an electric polarization density corresponding to the aligned molecular water dipoles moments, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic form of Gauss' equation. The electric field inside of a material having a uniform polarization density $P_{0}$ given by Eq. (6.3.3.15) of Haus and Melcher [93] is:

$$
\begin{equation*}
\mathbf{E}\left(H_{2} O\right)=\frac{P_{0}}{3 \varepsilon_{0}}\left(-\cos \theta \mathbf{i}_{r}+\sin \theta \mathbf{i}_{\theta}\right) \tag{16.49}
\end{equation*}
$$

The polarization density $P_{0}$ given by Eq. (6.3.3.3) of Haus and Melcher [93] is:

$$
\begin{equation*}
P_{0}=N \mu_{H_{2} O} \tag{16.50}
\end{equation*}
$$

where $\mu_{\mathrm{H}_{2} \mathrm{O}}$ is the dipole moment of water and $N$ is the number density of water dipoles given by the density $\rho_{\text {ice }}$ divided by the molecular weight $M W$ and multiplied by the Avogadro constant $N_{A}$ :

$$
\begin{equation*}
N=\frac{\rho_{i c e}}{M W} N_{A} \tag{16.51}
\end{equation*}
$$

Substitution of Eqs. (16.50) and (16.51) into Eq. (16.49) gives:

$$
\begin{equation*}
\mathbf{E}\left(H_{2} O\right)=\frac{\mu_{H_{2} O} \frac{\rho_{\text {ice }}}{M W} N_{A}}{3 \varepsilon_{0}}\left(-\cos \theta \mathbf{i}_{r}+\sin \theta \mathbf{i}_{\theta}\right) \tag{16.52}
\end{equation*}
$$

The energy of forming the condensed phase is that of the alignment of the water dipoles each comprised of two $O-H$ component dipoles where the angular dependence along the z-axis in ice is unity, and this condition applies even in the case of the local order in water. The corresponding energy $U\left(\mathrm{H}_{2} \mathrm{O}\right)$ per water dipole due to the polarization electric field of the lattice of hexagonal dipoles is given by:

$$
\begin{equation*}
U\left(H_{2} \mathrm{O}\right)=2 \mu_{\mathrm{H}_{2} \mathrm{O}} \cdot \mathbf{E}\left(\mathrm{H}_{2} \mathrm{O}\right)=\frac{-2\left(\mu_{\mathrm{H}_{2} \mathrm{O}}\right)^{2} \frac{\rho_{\text {ice }}}{M W} N_{A}}{3 \varepsilon_{0}} \tag{16.53}
\end{equation*}
$$

Substitution of the density of ice $\rho=\frac{0.92 \mathrm{~g}}{1 \times 10^{-6} \mathrm{~m}^{3}}$ [90], the $M W=18 \mathrm{~g} / \mathrm{mole}, N_{A}=6.0221415 \times 10^{23}$ molecules / mole, and the water dipole moment given by Eq. (16.16) with the predicted and experimental hexagonal bond angle of ice, $\theta_{\angle \mathrm{H}_{2} \mathrm{O}}=109.5^{\circ}$ [90]:

$$
\begin{equation*}
\mu_{\mathrm{H}_{2} \mathrm{O}}=2(1.51) \cos \left(109.5 / 2^{\circ}\right)=5.79898 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m} \tag{16.54}
\end{equation*}
$$

into Eq. (16.53) gives

$$
\begin{align*}
U\left(\mathrm{H}_{2} \mathrm{O}\right) & =\frac{-2\left(5.79898 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m}\right)^{2} \frac{\frac{0.92 \mathrm{~g}}{1 \times 10^{-6} \mathrm{~m}^{3}}}{18 \mathrm{~g} / \mathrm{mole}} 6.0221415 \times 10^{23} \text { molecules / mole }}{3 \varepsilon_{0}}  \tag{16.55}\\
& =-0.48643 \mathrm{eV}(-46.934 \mathrm{~kJ} / \text { mole })
\end{align*}
$$

$U\left(\mathrm{H}_{2} \mathrm{O}\right)$ is also the negative of $E_{\text {vapor, } 0^{\circ} \mathrm{C}}$, the energy of water initially at $0^{\circ} \mathrm{C}$ or the energy of vaporization of water at $0{ }^{\circ} \mathrm{C}$ :

$$
\begin{equation*}
E_{\text {vapor }, 0^{\circ} \mathrm{C}}=-U\left(\mathrm{H}_{2} \mathrm{O}\right)=0.48643 \mathrm{eV}(46.934 \mathrm{~kJ} / \text { mole }) \tag{16.56}
\end{equation*}
$$

The experimental energy of vaporization of water at $0^{\circ} \mathrm{C}$ (Type I ice) is [94] :

$$
\begin{equation*}
E_{\text {vapor }, 0^{\circ} \mathrm{C}}=45.054 \mathrm{~kJ} / \mathrm{mole} \tag{16.57}
\end{equation*}
$$

The calculated results based on first principles and given analytical equations are summarized in Table 16.19.

Table 16.19. The calculated and experimental geometrical and energy parameters of the $H$ bond of water of Type I ice.

| Parameter | Calculated | Experimental | Ref. for <br> Exp. |
| :--- | :---: | :---: | :---: |
| H Bond Length $2 c_{O \ldots H}^{\prime}$ <br> Nearest Neighbor Separation | $1.78219 \AA$ | $1.78 \AA$ | 88,89 |
| Distance 2 $c_{O \ldots H O}^{\prime}$ |  |  |  |$\quad 2.75377 \AA$|  |  |
| :--- | :--- |
| $\mathrm{H}_{2} \mathrm{O}$ Lattice Parameter $a_{l}$ | $4.49768 \AA$ |
| $\mathrm{H}_{2} \mathrm{O}$ Lattice Parameter $c_{l}$ | $7.34077 \AA$ |
| Energy of Vaporization of Water <br> at $0{ }^{\circ} \mathrm{C}$ | $46.934 \mathrm{~kJ} / \mathrm{mole}$ |

As the temperature increases, the corresponding molecular kinetic energy can excite a vibrational mode along the H bond axis. Concomitantly, the $O-H$ bond elongates and decreases in energy. As a consequence, the hydrogen bond achieves a partial bond order or partial three-centered $O-H-O$ bond, and the $H$ can undergo exchange between water molecules. The time-average effect of exchange is to decrease the statistical equilibrium separation distance of water molecules. In competition with the separation-distance decreasing effect of exchange is the increasing effect due to collisional impact and recoil as a function of increasing temperature. The former effect dominates from the temperature of ice to $4^{\circ} \mathrm{C}$ at which point water assumes a maximum density. Thereafter, the momentum imparted with water-water collisions overwhelms the decrease due to exchange, and the molecular separation statistically increases with temperature until a totally gaseous state is achieved at atmospheric pressure at $100^{\circ} \mathrm{C}$. Unit cells with increasing entropy can be derived from the ice unit cell by populating translational, rotational, and vibrational levels of molecules within the cells to match the internal energy at a given temperature. Using statistical mechanical models such as Boltzmann statistics to populate an increasing number of basis units cells of increasing disorder and based on the ice unit cell, the behavior of water as a function of temperature can be modeled over the range of states from ice to liquid to steam. The structure of each phase of water is then determined by the number of H bonds on average per water molecule. Based on the $10 \%$ energy change in the heat of vaporization in going from ice at $0^{\circ} \mathrm{C}$ to water at $100^{\circ} \mathrm{C}$ [94], the average number of H bonds per water molecule in boiling water is 3.6 . The H bond distance is calculated next using the enthalpy to form steam from boiling water.

## GEOMETRICAL PARAMETERS AND ENERGIES OF THE HYDROGEN BOND OF $\mathrm{H}_{2} \mathrm{O}$ IN THE VAPOR PHASE

Two or more water molecules can interact along the $O \cdots H$ or $H$ bond axis. In the gas phase, the maximum energy of interaction between water molecules of steam is equivalent to the negative of the heat of vaporization of water at the boiling point, $100^{\circ} \mathrm{C}$; otherwise, water vapor would form the corresponding condensed state. For the determination of the H -bond distance, the energy parameters, partial charge, and reduced mass are the same as those of the water molecules of ice given in Eq. (16.26) except that the negative of the experimental $E_{\text {vapor }, 100^{\circ} \mathrm{C}}=0.42137 \mathrm{eV}(40.657 \mathrm{~kJ} / \mathrm{mole})$ [94] is equated to the nascent covalent bond energy. The parameters are summarized in Table 16.20 and Eq. (16.58).

Table 16.20. The energy parameters $(\mathrm{eV})$ of the $O \cdots H$ functional group of the hydrogen bond of water vapor.

| Parameters | $O \cdots H$ Group |
| :---: | :---: |
| $\delta$ | 0.323 |
| $n_{1}$ | 2 |
| $C_{1}$ | 0.75 |
| $C_{2}$ | 1 |
| $c_{1}$ | 0.75 |
| $c_{2}$ | 1 |
| $C_{10}$ | 1.5 |
| $C_{2 o}$ | 1 |
| $V_{e}(e \mathrm{~V})$ | -15.20020 |
| $V_{p}(\mathrm{eV})$ | 14.08285 |
| $T(e V)$ | 1.35707 |
| $V_{m}(e V)$ | -0.67853 |
| $E$ (Ао/но) $(\mathrm{eV})$ | 0 |
|  | 0 |
| $E_{T}$ (Ао/но) $(\mathrm{eV})$ | 0 |
| $E_{T}\left(\mathrm{H}_{2} \mathrm{MO}\right)(\mathrm{eV})$ | -0.43882 |
| $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)(\mathrm{eV})$ | 0 |
| $E_{T}($ мо $)(\mathrm{eV})$ | -0.43882 |
| $\omega\left(10^{15} \mathrm{rad} / \mathrm{s}\right)$ | 4.20131 |
| $E_{K}(\mathrm{eV})$ | 2.76538 |
| $\bar{E}_{D}(e V)$ | -0.001444 |
| $\bar{E}_{\text {Kvib }}(\mathrm{eV})$ | 0.02033 |
| $\bar{E}_{\text {osc }}(\mathrm{eV})$ | 0.008724 |
| $E_{T}($ Group $)(\mathrm{eV})$ | -0.42137 |

Substitution of the parameters of Table 16.20 and $-E_{\text {vapor }, 0^{\circ} \mathrm{C}}$ (Eq. (16.57)) into Eq. (16.26) gives:

From the energy relationship given by Eq. (16.58) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $O \cdots H$ MO can be solved.

The most convenient way to solve Eq. (16.58) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a_{O \cdots H}=5.60039 a_{0}=2.96360 \times 10^{-10} \mathrm{~m} \tag{16.59}
\end{equation*}
$$

The component energy parameters at this condition are given in Table 16.20. Substitution of Eq. (16.59) into Eq. (16.22) gives

$$
\begin{equation*}
c_{O \ldots H}^{\prime}=1.93225 a_{0}=1.02250 \times 10^{-10} \mathrm{~m} \tag{16.60}
\end{equation*}
$$

and internuclear distance of the H bond:

$$
\begin{equation*}
2 c_{O \ldots H}^{\prime}=3.86450 a_{0}=2.04501 \times 10^{-10} \mathrm{~m} \tag{16.61}
\end{equation*}
$$

The experimental H bond distance $2 c_{o \ldots H}^{\prime}$ in the gas phase is [95]:

$$
\begin{equation*}
2 c_{O \ldots H}^{\prime}=2.02 \times 10^{-10} \mathrm{~m} \tag{16.62}
\end{equation*}
$$

and [96]

$$
\begin{equation*}
2 c_{O \ldots H}^{\prime}=2.05 \times 10^{-10} \mathrm{~m} \tag{16.63}
\end{equation*}
$$

The other H-bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.59) and (16.60) into Eq. (16.23) gives:

$$
\begin{equation*}
b_{O \cdots H}=c_{O \cdots H}=5.25650 a_{0}=2.78162 \times 10^{-10} \mathrm{~m} \tag{16.64}
\end{equation*}
$$

Substitution of Eqs. (16.59) and (16.60) into Eq. (16.24) gives:

$$
\begin{equation*}
e_{O \cdots H}=0.34502 \tag{16.65}
\end{equation*}
$$

Substitution of $2 c_{O \cdots H}^{\prime}$ (Eq. (16.61)) and $2 c_{O-H}^{\prime}$ (Eq. (13.185)) into Eq. (16.31) gives the nearest neighbor separation, the internuclear distance $2 c_{O \cdots H O}^{\prime}$ between the oxygen atoms of the $O-H \cdots O$ bond of water vapor:

$$
\begin{equation*}
2 c_{O \ldots H O}^{\prime}=2 c_{O \ldots H}^{\prime}+2 c_{O-H}^{\prime}=2.04501 \times 10^{-10} \mathrm{~m}+9.71574 \times 10^{-11} \mathrm{~m}=3.01658 \times 10^{-10} \mathrm{~m}=3.01658 \AA \tag{16.66}
\end{equation*}
$$

Using Eqs. (16.31), (16.34), and (16.63), the experimental nearest neighbor separation $2 c_{o \cdots н о}^{\prime}$ is [89, 96]:

$$
\begin{equation*}
2 c_{O \ldots H O}^{\prime}=2 c_{O \ldots H}^{\prime}+2 c_{O-H}^{\prime}=2.05 \times 10^{-10} \mathrm{~m}+9.70 \times 10^{-11} \mathrm{~m}=3.02 \times 10^{-10} \mathrm{~m}=3.02 \AA \tag{16.67}
\end{equation*}
$$

H-bonded water vapor molecules in steam are shown in Figure 16.11 using the color scale charge density of each water molecule.

Figure 16.11. Structure of steam. (A). Ensemble of gaseous water molecules undergoing elastic hard-sphere collisions. (B). H-bonded water vapor molecules using the color scale charge density of each $\mathrm{H}_{2} \mathrm{O}$ MO comprising the linear combination of two $O-H$-bond MOs.

The calculated results based on first principles and given by analytical equations are summarized in Table 16.21.
Table 16.21. The calculated and experimental geometrical and energy parameters of the H bond of steam.

| Parameter | Calculated | Experimental | Ref. for Exp. |  |
| :--- | :--- | :--- | :---: | :---: |

| Nearest <br> $2 c_{O \ldots H O}^{\prime}$ | Neighbor | Separation | Distance | $3.01658 \AA$ |

## GEOMETRICAL PARAMETERS AND ENERGIES OF THE HYDROGEN BOND OF $\mathrm{H}_{2} \mathrm{O}$ AND $\mathrm{NH}_{3}$

Similar to the water molecule, the ammonia molecule has a strong dipole moment along each of its $\mathrm{N}-\mathrm{H}$-bonds. The $\mathrm{NH}_{3}$ MO comprises the linear combination of three $N-H$-bond MOs. Each $N-H$-bond MO comprises the superposition of a $\mathrm{H}_{2}$ type ellipsoidal MO and the $N 2 p_{x}, N 2 p_{y}$, or $N 2 p_{z}$ AO with a relative $H$ partial orbital contribution to the MO of 0.75 . The solution of the geometrical parameters and component energies are given in the Ammonia ( $\mathrm{NH}_{3}$ ) section, and the color scale charge density of the $\mathrm{NH}_{3} \mathrm{MO}$ is shown in Figure 16.12.

Figure 16.12. $N H_{3}$ MO comprising the linear combination of three $N-H$-bonds. Each $N-H$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and the $N 2 p_{x}, N 2 p_{y}$, or $N 2 p_{z} \mathrm{AO}$. (A) Color scale, translucent view of the charge density of the $\mathrm{NH}_{3}$ MO shown obliquely from the top. For each $N-H$ bond, the ellipsoidal surface of each $H_{2}$-type ellipsoidal MO transitions to a $N 2 p$ AO. The $N 2 p$ shell, the $N 2 s$ shell, the $N 1 s$ shell, and the nuclei (red, not to scale) are shown. (B) Off-center cut-away view showing the complete inner most $N 1 s$ shell, and moving radially, the cross section of the $N 2 s$ shell, the $N 2 p$ shell, and the $H_{2}$-type ellipsoidal MO that transitions to a $N 2 p \mathrm{AO}$ for each $N-H$ bond. (C)-(E) Color scale, side-on, top, and bottom translucent views of the charge density of the $\mathrm{NH}_{3} \mathrm{MO}$, respectively.

Due to the interacting dipoles, hydrogen bonds also form between the nitrogen of ammonia and the hydrogen of water molecules. Water hydrogen bonds to ammonia molecules by interaction along the $N \cdots H O$ or $H$ bond axis. As shown in the Bond and Dipole Moments section, each $N-H$ bond of ammonia has a bond moment $\mu$ of 1.30 D corresponding to a $N$ component of partial charge of $-0.262 e$, and the $O-H$ bond has a bond moment $\mu$ of 1.51 D corresponding to a $H$ partial charge of +0.323 e . The thermodynamic basis of the H bond is the minimization of the Coulombic energy between the hydrogen bonded $\mathrm{H}^{\text {of }} \mathrm{H}_{2} \mathrm{O}$ and N of ammonia, limited by the formation of a nascent $\mathrm{N}-\mathrm{H}$ bond between these atoms that destabilizes the initial $O-H$ bond of the water molecule partner. As in the case of ice, the maximum electrostatic energy of the partial charges is calculated for the components along the H-bond axis. This energy is balanced by the total energy of the nascent bond that can form between the $N \cdots H$ atoms of the H bond. The bond length of the H bond, the internuclear distance between the $N$ and $H$ of the $N \cdots H$ bond, is calculated using Eq. (16.25) by a similar method as that used to calculate the $O \cdots H$ bond distance of ice. According to the method given in the Geometrical Parameters and Energies of the Hydrogen Bond of $\mathrm{H}_{2} \mathrm{O}$ section, the equilibrium distance $r_{e}$ or internuclear bond distance of $N \cdots H$ designated as $2 c_{N \cdots H}^{\prime}=r_{e}$ is determined by the condition that the total energy of the nascent $H_{2}$-type ellipsoidal MO formed from the atoms of the $N \cdots H$ bond is equal to the maximum Coulombic energy between the partial charges of the $N$ and $H$ atoms of the H bond.

The maximum Coulumbic energy corresponds to the minimum separation distance of $N$ and $H$ atoms corresponding to the alignment along the $N \cdots H$ bond axis. The corresponding distance from the $\delta^{+}$of the $\mathrm{H}_{2} \mathrm{OH} \mathrm{H}$ and the $\mathrm{NH}_{3} \mathrm{~N}$ is the distance $2 c_{N \cdots H}^{\prime}$ between the $N$ and $H$ nuclei of the $N \cdots H$ bond. Then, the maximum Coulomb energy $E_{\text {Coulomb }}(H-b o n d)$ between the atoms of the $N \cdots H$ bond due to the $\delta^{-}$on the nitrogen atom with the $\delta^{+}$centered on the nucleus of hydrogen is:

$$
\begin{equation*}
E_{\text {Coulomb }}(H-\text { bond })=\frac{-\delta_{N}^{-} \delta_{H}^{+} e^{2}}{4 \pi \varepsilon_{0} 2 c_{N \cdots H}^{\prime}} \tag{16.68}
\end{equation*}
$$

Eq. (16.68) is the energy to be equated to that of the nascent bonds involving the atoms of the H bond.
For the determination of the H -bond distance, the energy parameters of the nascent $N-H$ bond are the same as those of ammonia given in the Ammonia $\left(\mathrm{NH}_{3}\right)$ section except that any parameter due to matching AO's, $E_{T}(\mathrm{AO} / \mathrm{HO})$ and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$, is zero since only the energies of the MO electrons to form the $N \cdots H$ MO are considered. The energy of Eq. (16.68) is multiplied by three to match the total energy of the three $N-H$ bond MOs of ammonia. The partial charges $\delta=q / e$ from Table 16.17 are -0.262 and +0.323 , and the reduced mass is $\mu=\frac{14}{15}$. The parameters are summarized in Table 16.22 and Eq. (16.69).

Table 16.22. The energy parameters $(e V)$ of the $N \cdots H$ functional group of the hydrogen bond of the ammonia-water molecular dimer.

| Parameters | $\begin{aligned} & N \cdots H \\ & \text { Group } \end{aligned}$ |

| $E_{T}($ Group $)(e V)$ | 1.75603 |
| $E_{T}($ Group $)(e V)$ per $N-H$ | 0.58534 |

Substitution of the parameters of Table 16.22 into Eq. (16.25) with $R=a_{N \cdots H}$ gives:

From the energy relationship given by Eq. (16.69) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $N \cdots H$ MO can be solved.

The most convenient way to solve Eq. (16.69) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a_{N \ldots H}=5.43333 a_{0}=2.87519 \times 10^{-10} \mathrm{~m} \tag{16.70}
\end{equation*}
$$

The component energy parameters at this condition are given in Table 16.22. Substitution of Eq. (16.70) into Eq. (16.22) gives

$$
\begin{equation*}
c_{N \ldots H}^{\prime}=1.96707 a_{0}=1.04093 \times 10^{-10} \mathrm{~m} \tag{16.71}
\end{equation*}
$$

and internuclear distance of the H bond:

$$
\begin{equation*}
2 c_{N \ldots H}^{\prime}=3.93414 a_{0}=2.08186 \times 10^{-10} m=2.08186 \AA \tag{16.72}
\end{equation*}
$$

The experimental H bond distance $2 c_{N \ldots H}^{\prime}$ in the gas phase is [96, 97]:

$$
\begin{equation*}
2 c_{N \ldots H O}^{\prime}=2.02 \times 10^{-10} \mathrm{~m} \tag{16.73}
\end{equation*}
$$

The other H-bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.70) and (16.71) into Eq. (16.23) gives

$$
\begin{equation*}
b_{N \ldots H}=c_{N \ldots H}=5.06475 a_{0}=2.68015 \times 10^{-10} \mathrm{~m} \tag{16.74}
\end{equation*}
$$

Substitution of Eqs. (16.70) and (16.71) into Eq. (16.24) gives:

$$
\begin{equation*}
e_{N \cdots H}=0.36204 \tag{16.75}
\end{equation*}
$$

The addition of $2 c_{N \ldots H}^{\prime}$ (Eq. (16.72)) and $2 c_{O-H}^{\prime}$ (Eq. (13.185)) gives the nearest neighbor separation, the internuclear distance $2 c_{N \cdots H O}^{\prime}$ between the nitrogen and oxygen atoms of the $N \cdots H-O$ bond of the ammonia-water molecular dimer:

$$
\begin{align*}
2 c_{N \ldots H O}^{\prime} & =2 c_{N \ldots H}^{\prime}+2 c_{O-H}^{\prime}=2.08186 \times 10^{-10} m+9.71574 \times 10^{-11} \mathrm{~m}  \tag{16.76}\\
& =3.05343 \times 10^{-10} \mathrm{~m}=3.05343 \mathrm{~A}
\end{align*}
$$

The addition of the experimental $2 c_{N \ldots H}^{\prime}$ (Eq. (16.73)) and $2 c_{O-H}^{\prime}$ (Eq. (13.185)) gives the experimental nearest neighbor separation $2 c_{N \cdots H O}^{\prime}[96,89]$ :

$$
\begin{align*}
2 c_{N \ldots H O}^{\prime} & =2 c_{N \ldots H}^{\prime}+2 c_{O-H}^{\prime}=2.02 \times 10^{-10} m+9.70 \times 10^{-11} \mathrm{~m}  \tag{16.77}\\
& =2.99 \times 10^{-10} \mathrm{~m}=2.99 A
\end{align*}
$$

H-bonded ammonia-water molecular dimer is shown in Figure 16.13 using the color scale charge density of each molecule.

## Dipole Moments and Interactions

Figure 16.13. Structure of the $H_{3} N \cdots H-O H$ H bond. The H-bonded ammonia-water vapor molecular dimer using the color scale charge density of each $\mathrm{NH}_{3}$ and $\mathrm{H}_{2} \mathrm{O}$ MO comprising the linear combination of three $\mathrm{N}-\mathrm{H}$ and two $\mathrm{O}-\mathrm{H}$-bond MOs, respectively.

The energy of forming the dimer in the gas phase is that of the alignment of the ammonia dipole moment in the electric field of the $H-O$ water dipole. Using $\mu_{H_{3} N}=1.467 D=4.89196 X 10^{-30} \mathrm{C} \cdot \mathrm{m}$ Eq. (16.18), $\mu_{H-O, H_{2} O}=1.51 D=5.02385 \times 10^{-30} C \cdot m$ (Table 16.17), and the $N \cdots H$ distance, $2 c_{N \cdots H}^{\prime}=2.08186 \times 10^{-10} m$ (Eq. (16.72)), the $N \cdots H$ bond dissociation energy $E_{D}(N \cdots H)$ of the ammonia-water molecular dimer is:

$$
\begin{align*}
E_{D}(N \cdots H) & =\mu_{H_{3} N} \cdot \frac{2 \mu_{H-O, H_{2} O}}{4 \pi \varepsilon_{0}\left(2 c_{N \cdots H}^{\prime}\right)^{3}} \\
& =\frac{\left(4.89196 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m}\right)\left(5.02385 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m}\right)}{4 \pi \varepsilon_{0}\left(2.08186 \times 10^{-10} \mathrm{~m}\right)^{2}}=29.48 \mathrm{~kJ} \tag{16.78}
\end{align*}
$$

The experimental $N \cdots H$ bond dissociation energy between amino $N$ and hydroxyl $H$ is approximately [98]:

$$
\begin{equation*}
E_{D}(N \cdots H)=29 k J \tag{16.79}
\end{equation*}
$$

The calculated results based on first principles and given by analytical equations are summarized in Table 16.23.
Table 16.23. The calculated and experimental geometrical and energy parameters of the H-bonded ammonia-water vapor molecular dimer.

| $N \cdots H$ Bond Dissociation Energy |  |  |  |  |

## GEOMETRICAL PARAMETERS DUE TO THE INTERPLANE VAN DER WAALS COHESIVE ENERGY OF GRAPHITE

Eq. (16.25) can be applied to other solids such as graphite. Graphite is an allotrope of carbon that comprises planar sheets of covalently bound carbon atoms arranged in hexagonal aromatic rings of a macromolecule of indefinite size. The structure of graphite is shown in Figures 16.14A and B. The structure shown in Figure 16.14 has been confirmed directly by TEM imaging, and the Pi cloud predicted by quantum mechanics has been dispatched [99].

Figure 16.14. The structure of graphite. (A) Single plane of macromolecule of indefinite size. (B) Layers of graphitic planes.
(A)

(B)

As given in the Graphite section, the structure of the indefinite network of aromatic hexagons of a sheet of graphite is solved using a linear combination of aromatic $C \stackrel{3 e}{=} C$ aromatic bonds comprising $(0.75)(4)=3$ electrons according to Eq. (15.161). In graphite, the minimum energy structure with equivalent carbon atoms wherein each carbon forms bonds with three other such carbons requires a redistribution of charge within an aromatic system of bonds. Considering that each carbon contributes four bonding electrons, the sum of electrons of graphite at a vertex-atom comprises four from the vertex atom plus two from each of the two atoms bonded to the vertex atom where the latter also contribute two each to the juxtaposed bond. These eight electrons are distributed equivalently over the three bonds of the group such that the electron number assignable to each bond is $\frac{8}{3}$. Thus, the $C \stackrel{8 / 3 e}{=} C$ functional group of graphite comprises the aromatic bond with the exception that the electron-number per bond is $\frac{8}{3}$. The sheets, in turn, are bound together by weaker intermolecular van der Waals forces. The geometrical and energy parameters of graphite are calculated using Eq. (16.25) with the van der Waals energy equated to the nascent bond energy.

The van der Waals energy is due to mutually induced nonpermanent dipoles in near-neighbor bonds. Albeit, the $C \stackrel{8 / 3 e}{=} C$ functional group is symmetrical such that it lacks a permanent dipole moment, a reversible dipole can be induced upon van der Waals bonding. The parameters of the $C \stackrel{8 / 3 e}{=} C$ functional group are the same as those of the aromatic $C={ }^{3 e} C$ functional group,
 of Eq. (15.51) for the aromatic $C=\frac{3 e}{=} C$-bond MO is $C_{2}\left(\right.$ aromatic $\left.C 2 s p^{3} H O\right)=c_{2}\left(\right.$ aromaticC $\left.2 s p^{3} H O\right)=0.85252$ (Eq. (15.162)) and $\quad E_{\text {Coulomb }}\left(C_{\text {benzene }}, 2 s p^{3}\right) \quad$ is $\quad 15.95955 \mathrm{eV} \quad$ (Eq. (14.245)), $\quad E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV} \quad$ (Eq. (14.143)) and $2 c^{\prime}=1.39140 \times 10^{-10} m$ (Table 15.214), the van der Waals dipole of graphite is given in Table 16.24.

Table 16.24. The parameters and van der Waals dipole bond moment of the $C \stackrel{8 / 3 e}{=} C$ functional group of graphite.

| Functional <br> Group | $n_{1}$ | $\left(c_{1}\right) c_{2}$ | $\left(C_{1}\right)$ <br> $C_{2}$ | $E_{B}($ valence $)$ | $E_{A}($ valence $)$ | $\frac{q}{e}$ | Bond Length <br> $2 c^{\prime}(\AA)$ | Bond Moment <br> $\mu(\mathrm{D})$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $C \stackrel{8 / 3 e}{=} C$ | $\frac{8}{3}$ | 0.85252 | 1 | 14.82575 | 15.95955 | 0.36101 | 1.3914 | 2.41270 |

The interaction between a dipole in one plane with the nearest neighbor in another plane is zero in the case that the aromatic rings of one layer are aligned such that they would superimpose as the interlayer separation goes to zero. But, the energy of interaction is nonzero when one plane is translated relative to a neighboring plane. A minimum equal-energy is achieved throughout the graphite structure when each layer is displaced by $2 c_{C=C}^{\prime}{ }_{C=C}$, the bond length of $C \stackrel{8 / 3 e}{=} C$, along an intra-planar $C_{2}$ axis relative to the next as shown in Figure 16.14B. Then, a pair of dipoles exists for each dipole of a given plane with one dipole above and one below in neighboring planes such that all planes can be equivalently bound by van der Waals forces. In this case, the distance $r_{\mu_{1} \ldots \mu_{2}}$ between dipole $\mu_{1}$ in one plane and its nearest neighbor $\mu_{2}$ above or below on a neighboring and
$2 c_{\substack{\text { 3e } \\ c=C}}^{\prime}$-displaced plane is:

$$
\begin{equation*}
r_{\mu_{1} \ldots \mu_{2}}=\sqrt{\binom{2 c^{\prime}{ }_{C=C}^{\prime o}}{c^{\circ}}^{2}+\left(2 c_{C \ldots C}^{\prime}\right)^{2}} \tag{16.80}
\end{equation*}
$$

where $2 c_{C \ldots C}^{\prime}$ is the interplane distance. The alignment angle $\theta_{\mu_{1} \ldots \mu_{2}}$ between the dipoles is:

$$
\begin{equation*}
\theta_{\mu_{1} \ldots \mu_{2}}=\sin ^{-1} \frac{2 c_{C \ldots C}^{\prime}}{r_{\mu_{1} \ldots \mu_{2}}}=\sin ^{-1} \frac{2 c_{C \ldots C}^{\prime}}{\sqrt{\binom{2 c^{\prime} c_{\text {3e }}}{C=C}^{2}+\left(2 c_{C \ldots C}^{\prime}\right)^{2}}} \tag{16.81}
\end{equation*}
$$

The van der Waals energy is the potential energy between interacting neighboring pairs of $C \stackrel{8 / 3 e}{=} C$ induced dipoles. Using Eqs. (16.80-16.81), $\quad \mu_{C} \stackrel{8 / 3 e}{=}=2.41270 D=8.04790 X 10^{-30} C \cdot m \quad$ (Table 16.24), and the $C \stackrel{8 / 3 e}{=} C \quad$ distance, $2 c_{C}^{\prime} \stackrel{8 / 3 e}{=}=1.39140 \times 10^{-10} \mathrm{~m}$ (Table 15.214), the van der Waals energy of graphite between two planes at a vertex atom is:

$$
\begin{align*}
E_{\text {van der Waals }}(\text { graphite }) & =(3) \frac{2\left(\mu_{C}{ }_{\substack{8 / 3 c}}\right)^{2}}{4 \pi \varepsilon_{0}\left(r_{\mu_{1} \ldots \mu_{2}}\right)^{3}} \cos \theta_{\mu_{1} \ldots \mu_{2}} \\
& =\binom{\frac{6\left(8.04790 \times 10^{-30} C \cdot m\right)^{2}}{4 \pi \varepsilon_{0}\left(\left(1.39140 \times 10^{-10} m\right)^{2}+\left(2 \sqrt{\frac{a_{C \ldots C} a_{0}}{2 C_{1} C_{2}}}\right)^{2}\right)^{1.5}}}{\cos \sin ^{-1} \frac{2 \sqrt{\frac{a_{C \ldots C} a_{0}}{2 C_{1} C_{2}}}}{\sqrt{\left(1.39140 \times 10^{-10} m\right)^{2}+\left(2 \sqrt{\frac{a_{C \ldots C} a_{0}}{2 C_{1} C_{2}}}\right)^{2}}}} \tag{16.82}
\end{align*}
$$

where there are three bonds at each vertex atom.
The graphite inter-plane distance of $3.5 \AA[100]$ is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.82)) between dipoles of two neighboring planes equated to the nascent bond energy. The energy matching parameter $c_{2}$ is the same that of the graphite sheet corresponding to the aromatic carbons as given in the Graphite section, and the reduced mass is $\mu=6$. The parameters are summarized in Table 16.25 and Eq. (16.83).

Table 16.25. The energy parameters ( eV ) of the graphite interplanar functional group ( $C_{\text {aromatic }} \cdots C_{\text {aromatic }}$ ).

| Parameters | $\begin{gathered} C_{\text {aromatic }} \cdots C_{\text {aromatic }} \\ \text { Group } \\ \hline \end{gathered}$ |

| $E_{T}($ Group $)(\mathrm{eV})$ | -0.14905 |

Substitution of the parameters of Table 16.25 and the interlayer cohesive energy of graphite (Eq. (16.82)) into Eq. (16.25) with $R=a_{C \ldots C}$ gives:

$$
\left.\frac{-6\left(8.04790 \times 10^{-30} C \cdot m\right)^{2}}{4 \pi \varepsilon_{0}\left(\left(1.39140 \times 10^{-10} m\right)^{2}+\left(2 \sqrt{\frac{a_{C \ldots C} a_{0}}{2(0.5)}}\right)^{2}\right.}\right)^{1.5} \cos \sin ^{-1} \frac{2 \sqrt{\frac{a_{C \ldots C} a_{0}}{2(0.5)}}}{\sqrt{\left(1.39140 \times 10^{-10} m\right)^{2}+\left(2 \sqrt{\frac{a_{C \ldots C} a_{0}}{2(0.5)}}\right)^{2}}}
$$

$$
\left.=\left\{\begin{array}{l}
\left(\frac { - e ^ { 2 } } { 8 \pi \varepsilon _ { 0 } \sqrt { \frac { a _ { C \ldots C } a _ { 0 } } { 2 ( 0 . 5 ) } } } \left((0.85252)\left(2-\frac{1}{2} \frac{a_{0}}{a_{C \ldots C}}\right) \ln \frac{a+\sqrt{\frac{a_{C \ldots C} a_{0}}{2(0.5)}}}{a-\sqrt{\frac{a_{C \ldots C} a_{0}}{2(0.5)}}}-1\right.\right. \tag{16.83}
\end{array}\right)\right)\left(1+2 \sqrt{\frac{e^{2}}{2 \hbar \sqrt{\frac{(0.5) \frac{e^{2}}{4 \pi \varepsilon_{o}\left(a_{C \ldots C}\right)^{3}}}{m_{e}}}}{ }^{\frac{m_{e} c^{2}}{\frac{(0.85252) e^{2}}{8 \pi \varepsilon_{o}\left(a_{C \ldots C}\right)^{3}}}-\frac{8 \pi \varepsilon_{o}\left(a_{C \ldots C}+\sqrt{\frac{a_{C \ldots C} a_{0}}{2(0.5)}}\right.}{3}}}\right)
$$

From the energy relationship given by Eq. (16.83) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $C \cdots C$ MO can be solved.

The most convenient way to solve Eq. (16.83) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a_{C \cdots C}=11.00740 a_{0}=5.82486 \times 10^{-10} \mathrm{~m} \tag{16.84}
\end{equation*}
$$

The component energy parameters at this condition are given in Table 16.25. Substitution of Eq. (16.84) into Eq. (16.22) gives:

$$
\begin{equation*}
c_{C \ldots C}^{\prime}=3.31774 a_{0}=1.75567 \times 10^{-10} \mathrm{~m} \tag{16.85}
\end{equation*}
$$

and internuclear distance of the graphite interplane bond at vacuum ambient pressure:

$$
\begin{equation*}
2 c_{C \ldots C}^{\prime}=6.63548 a_{0}=3.51134 \times 10^{-10} m=3.51134 \AA \tag{16.86}
\end{equation*}
$$

The experimental graphite interplane distance $2 c_{C \ldots C}^{\prime}$ is [100]:

$$
\begin{equation*}
2 c_{C \ldots C}^{\prime}=3.5 \times 10^{-10} m=3.5 \AA \tag{16.87}
\end{equation*}
$$

The other interplane bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.84) and (16.85) into Eq. (16.23) gives:

$$
\begin{equation*}
b_{C \cdots C}=c_{C \cdots C}=10.49550 a_{0}=5.55398 \times 10^{-10} \mathrm{~m} \tag{16.88}
\end{equation*}
$$

Substitution of Eqs. (16.84) and (16.85) into Eq. (16.25) gives:

$$
\begin{equation*}
e_{C \ldots C}=0.30141 \tag{16.89}
\end{equation*}
$$

Using Eqs. (16.80) and (16.86), the distance $r_{\mu_{1} . . \mu_{2}}$ between dipole $\mu_{1}$ on one plane and its nearest neighbor $\mu_{2}$ above or below on a juxtaposed and $2 c_{\substack{\text { se } \\ C=C}}^{\text {- }}$-displaced plane is:

$$
\begin{equation*}
r_{\mu_{1} \ldots \mu_{2}}=3.77697 \times 10^{-10} \mathrm{~m} \tag{16.90}
\end{equation*}
$$

Using Eqs. (16.81) and (16.86), the alignment angle $\theta_{\mu_{1} \ldots \mu_{2}}$ between the dipoles is:

$$
\begin{equation*}
\theta_{\mu_{1} \ldots \mu_{2}}=68.38365^{\circ} \tag{16.91}
\end{equation*}
$$

Using Eqs. (16.82) and (16.90-91), the van der Waals energy per carbon atom is:

$$
\begin{equation*}
E_{\text {van der Waals }}(\text { graphite } / C)=0.04968 \mathrm{eV} \tag{16.92}
\end{equation*}
$$

The experimental van der Waals energy per carbon atom is [101]:

$$
\begin{equation*}
E_{\text {van der Waals }}(\text { graphite } / C)=0.052 \mathrm{eV} \tag{16.93}
\end{equation*}
$$

The calculated results based on first principles and given by analytical equations are summarized in Table 16.26.
Table 16.26. The calculated and experimental geometrical parameters and interplane van der Waals cohesive energy of graphite.

| Parameter | Calculated | Experimental | Ref. for Exp. |
| :--- | :---: | :---: | :---: |
| Graphite Interplane Distance $2 c_{C \ldots C}^{\prime}$ | $3.51134 \AA$ | $3.5 \AA$ | 100 |
| van der Waals Energy per Carbon Atom | 0.04968 eV | 0.052 eV | 101 |

Graphite has a high cohesive energy due to its significant van der Waals dipole bond moment of 2.41270D. Other species such as atoms and molecules having mirror symmetry and consequently no permanent dipole moment also form reversible van der Waals dipole bond moments. Different phases can be achieved according to the extent of the van der Waals dipole bonding as the internal energy as a function of temperature and pressure changes analogously to the H -bonded system water that can exist as ice, water, and steam. Thus, the factors in the van der Waals bonding can give rise to numerous material behaviors. In the case of atoms such as noble gas atoms and certain diatomic molecules such as hydrogen, the moments, their interaction energies, and the corresponding nascent bond energies are much smaller. Thus, except at cryogenic temperatures, these elements exist as gases, and even at temperatures approaching absolute zero, solidification of helium has not been achieved in the absence of high pressure. This is due to the nature of the induced dipoles and van der Waals phenomena in helium. Since this system is a good example of van der Waals forces in atoms, it will be treated next.

## GEOMETRICAL PARAMETERS AND ENERGIES DUE TO THE INTERATOMIC VAN DER WAALS COHESIVE ENERGY OF LIQUID HELIUM

Noble gases such as helium are typically gaseous and comprised of non-interacting atoms having no electric or magnetic multipoles. But, at very low temperatures it is possible to form diffuse diatomic molecules, or alternatively, these gases may be condensed with the formation of mutually induced van der Waals dipole interactions. As a measure of the nascent bond between two noble gas atoms used to calculate the limiting separation for condensation, consider that the experimental bond energies of diatomic molecules of helium and argon, for example, are only 49.7 meV and 49 meV , respectively [21]. This is a factor of about 100 smaller than the bond energy of a carbon-carbon bond that is the form of nascent bond in graphite. Thus, the corresponding energy of the interspecies interaction is smaller and the van der Waals spacing is larger, except wherein the nascent bond energy as a function of separation distance mitigates this relationship to some extent. The nature of the helium bonding is solved using the same approach as that of other functional groups given in the Organic Molecular Functional Groups and Molecules section.

Helium is a two-electron neutral atom with both electrons paired as mirror-image current densities in a shell of radius $0.566987 \mathrm{a}_{0}$ (Eq. (7.35)). Thus, in isolation or at sufficient separation, there is no energy between helium atoms. The absence of any force such as so-called long-range London forces having a $r^{-n} ; n>2$ dependency is confirmed by elastic electron scattering from helium atoms as shown in the Electron Scattering Equation for the Helium Atom Based on the Orbitsphere Model section. However, reversible mutual van der Waals dipoles may be induced by collisions when the atoms are in close proximity such that helium gas can condense into a liquid. The physics is similar to the case of graphite except that the dipoles are atomic rather than molecular, and in both cases the limiting separation is based on the formation of a nascent bond to replace the dipole-dipole interaction. Thus, Eq. (16.25) can also be applied to atoms such as helium.

The van der Waals bonding in the helium atom involves hybridizing the one $1 s \mathrm{AO}$ into $1 s^{1} \mathrm{HO}$ orbitals containing two electrons. The total energy of the state is given by the sum over the two electrons. The sum $E_{T}\left(H e, 1 s^{1}\right)$ of experimental energies [15] of He and $\mathrm{He}^{+}$is:

$$
\begin{align*}
E_{T}\left(H e, 1 s^{1}\right) & =54.41776 \mathrm{eV}+24.587387 \mathrm{eV}  \tag{16.94}\\
& =79.005147 \mathrm{eV}
\end{align*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{1 s^{1}}$ of the Hels ${ }^{1}$ shell may be calculated from the Coulombic energy using Eq. (15.13):

$$
\begin{equation*}
r_{1 s^{s^{\prime}}}=\sum_{n=0}^{1} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 79.005147 \mathrm{eV})}=\frac{3 e^{2}}{8 \pi \varepsilon_{0}(e 79.005147 \mathrm{eV})}=0.51664 a_{0} \tag{16.95}
\end{equation*}
$$

where $Z=2$ for helium. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(H e, 1 s^{1}\right)$ of the outer electron of the van der Waals bound Hels ${ }^{1}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(H e, 1 s^{1}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{1 s^{1}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.51664 a_{0}}=-26.335049 \mathrm{eV} \tag{16.96}
\end{equation*}
$$

To meet the equipotential condition of the union of the two Hels ${ }^{1}$ HOs in a nascent bond, $c_{2}$ of Eqs. (15.2-15.5) and Eq. (15.61) for the nascent $\mathrm{He}-\mathrm{He}$-bond MO is given by Eq. (15.75) as the ratio of the valance energy of the He AO , $E(H e)=-24.587387 \mathrm{eV}$ and the magnitude of $E_{\text {Coulomb }}\left(H e, 1 s^{1}\right)$ (Eq. (16.96)):

$$
\begin{equation*}
c_{2}\left(H e-H e, H e l s^{1} H O\right)=\frac{24.587387 \mathrm{eV}}{26.33505 \mathrm{eV}}=0.93364 \tag{16.97}
\end{equation*}
$$

The opposite charge distributions act as symmetrical point charges at the point of maximum separation, each being centered at $1 / 2$ the He -atom radius from the origin. Using the parameters of Eq. (16.97) and $2 c^{\prime}=0.51664 a_{0}=2.73395 \times 10^{-11} \mathrm{~m}$ (Eq. (16.95)), the van der Waals dipole of helium is given in Table 16.27.

Table 16.27. The parameters and van der Waals dipole bond moment of the He functional group of liquid helium.

| Functional <br> Group | $n_{1}$ | $\left(c_{1}\right) c_{2}$ | $\left(C_{1}\right) C_{2}$ | $E_{B}$ (valence) | $E_{A}($ valence $)$ | $\frac{q}{e}$ | Bond <br> Length <br> $2 c^{\prime}(\AA)$ | Bond <br> Moment <br> $\mu(\mathrm{D})$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| He | 1 | 0.93364 | 1 | 24.587387 | 26.33505 | 0.13744 | 0.273395 | 0.18049 |

As in the case with graphite, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{H e}=0.18049 D=6.02040 \times 10^{-31} \mathrm{C} \cdot \mathrm{m}$ (Table 16.27), the van der Waals energy is:

$$
\begin{equation*}
E_{\text {van der Waals }}(H e)=2 \frac{2\left(\mu_{H e}\right)^{2}}{4 \pi \varepsilon_{0}\left(r_{\text {He...He }}\right)^{3}}=\left(\frac{2\left(6.02040 X 10^{-31} C \cdot m\right)^{2}}{4 \pi \varepsilon_{0}\left(2 \sqrt{\frac{a_{H e \cdots H e} a_{0}}{2 C_{1} C_{2}}}\right)^{3}}\right) \tag{16.98}
\end{equation*}
$$

where there are two bonds at each vertex atom.
The helium interatomic distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.98)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter $c_{2}$ is the same as that of the helium dipole, and the reduced mass is $\mu=2$. The parameters are summarized in Table 16.28 and Eq. (16.99).

Table 16.28. The energy parameters $(\mathrm{eV})$ of the helium functional group ( $\mathrm{He} \cdots \mathrm{He}$ ) .

| Parameters | $\mathrm{He} \cdots \mathrm{He}$ Group |
| :---: | :---: |
| $n_{1}$ | 1 |
| $C_{1}$ | 0.5 |
| $\mathrm{C}_{2}$ | $0.93364^{-1}$ |
| $c_{1}$ | 1 |
| $c_{2}$ | 0.93364 |
| $C_{1 o}$ | 0.5 |
| $C_{20}$ | $0.93364^{-1}$ |
| $V_{e}(\mathrm{eV})$ | -3.96489 |
| $V_{p}(e V)$ | 3.88560 |
| $T(\mathrm{eV})$ | 0.15095 |
| $V_{m}(\mathrm{eV})$ | -0.07548 |
| $E$ ( оо/но) (eV) | 0 |
| $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}($ Ао/ HO$)(\mathrm{eV})$ | 0 |
| $E_{T}$ (Ао/но) $(\mathrm{eV})$ | 0 |
| $E_{T}\left(\mathrm{H}_{2} \mathrm{MO}\right)(\mathrm{eV})$ | -0.00382 |
| $E_{T}\left(\right.$ atom - atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)(\mathrm{eV})$ | 0 |

| $E_{T}($ Group $)(\mathrm{eV})$ | -0.00160 |

Substitution of the parameters of Table 16.28 and the interatomic cohesive energy of helium (Eq. (16.89)) into Eq. (16.25) with $R=a_{\text {He } \cdots \text { He }}$ gives:

$$
\frac{-4\left(6.02040 X 10^{-31} C \cdot m\right)^{2}}{4 \pi \varepsilon_{0}\left(2 \sqrt{\frac{a_{\text {He } \cdots{ }^{+}{ }_{e}} a_{0}}{2(0.5)(0.93364)^{-1}}}\right)^{3}}
$$

From the energy relationship given by Eq. (16.99) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $\mathrm{He} \cdots \mathrm{He}$ MO can be solved.

The most convenient way to solve Eq. (16.99) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a_{H e \cdots H e}=13.13271 a_{0}=6.94953 \times 10^{-10} \mathrm{~m} \tag{16.100}
\end{equation*}
$$

The component energy parameters at this condition are given in Table 16.28. Substitution of Eq. (16.100) into Eq. (16.22) gives

$$
\begin{equation*}
c_{H e \cdots H e}^{\prime}=3.50160 a_{0}=1.85297 \times 10^{-10} \mathrm{~m} \tag{16.101}
\end{equation*}
$$

and internuclear distance between neighboring helium atoms:

$$
\begin{equation*}
2 c_{H e \cdot . H e}^{\prime}=7.00320 a_{0}=3.70593 \times 10^{-10} \mathrm{~m}=3.70593 \AA \tag{16.102}
\end{equation*}
$$

The experimental helium interatomic distance $2 c_{C \ldots C}^{\prime}$ at 4.24 K and $<2.25 \mathrm{~K}$ are [102]:

$$
\begin{align*}
& 2 c_{\text {He } \cdots \text { He }}^{\prime}(4.24 \mathrm{~K})=3.72 \times 10^{-10} \mathrm{~m}=3.72 \AA  \tag{16.103}\\
& 2 c_{\text {He...Нe }}^{\prime}(<2.25 \mathrm{~K})=3.70 \times 10^{-10} \mathrm{~m}=3.70 \AA
\end{align*}
$$

The other interatomic bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.100) and (16.101) into Eq. (16.23) gives

$$
\begin{equation*}
b_{H e \cdots H e}=c_{H e \cdots H e}=12.65729 a_{0}=6.69795 \times 10^{-10} \mathrm{~m} \tag{16.104}
\end{equation*}
$$

Substitution of Eqs. (16.100) and (16.101) into Eq. (16.25) gives:

$$
\begin{equation*}
e_{H e \cdots H e}=0.26663 \tag{16.105}
\end{equation*}
$$

Using Eqs. (16.89) and (16.102) and the relationship that there are two van der Waals bonds per helium atom and two atoms per bond, the van der Waals energy per helium atom is:

$$
\begin{equation*}
E_{\text {van der Wals }}(\text { liquid } \mathrm{He} / \mathrm{He})=0.000799 \mathrm{eV} \tag{16.106}
\end{equation*}
$$

The experimental van der Waals energy calculated from the heat of vaporization per helium atom is [103]:

$$
\begin{equation*}
E_{\text {van der Wals }}(\text { liquid He })=E_{\text {vapor }, 4.221 \mathrm{~K}}=0.0829 \mathrm{~kJ} / \text { mole }=0.000859 \mathrm{eV} / \mathrm{He} \tag{16.107}
\end{equation*}
$$

At 1.7 K , the viscosity of liquid helium is close to zero, and a characteristic roton scattering dominates over phonon scattering at this temperature and below [104]. The van der Waals bond energy is also equivalent to the roton energy [105, 106]

$$
\begin{equation*}
E_{\text {roton }}(\text { liquid } \mathrm{He})=8.7 \mathrm{~K}=0.00075 \mathrm{eV} \tag{16.108}
\end{equation*}
$$

and the roton is localized within a region of radius $\approx 3.7-4.0 \AA[104,106-108]$ that matches the $\mathrm{He} \cdots \mathrm{He}$ van der Waals bond distance (Eq. (16.102)). The origin of the roton energy and its cross section as belonging to the van der Waals bond resolves its nature. Independent of this result, the modern view of the roton is that it is not considered associated with the excitation of vorticity as it was historically; rather it is considered to be due to short-wavelength phonon excitations [105]. Its role in scattering free electrons in superfluid helium is discussed in the Free Electrons in Superfluid Helium are Real in the Absence of

Measurement Requiring a Connection of $\psi$ to Physical Reality section. The calculated results based on first principles and given by analytical equations are summarized in Table 16.29.

Table 16.29. The calculated and experimental geometrical parameters and interatomic van der Waals cohesive energy of liquid helium.

| Parameter | Calculated | Experimental | Ref. for Exp. |
| :--- | :---: | :---: | :---: |
| Liquid Helium Interatomic Distance $2 c_{C \ldots C}^{\prime}$ | $3.70593 \AA$ | $3.72 \AA(\mathrm{~T}=4.24 \mathrm{~K})$ | 102 |
| Roton Length Scale | $3.70593 \AA$ | $3.70(\mathrm{~T}<2.25 \mathrm{~K})$ | $104,106-108$ |
| van der Waals Energy per Helium Atom | 0.000799 eV | 0.000859 eV | 103 |
| $(4.221 \mathrm{~K})$ | 0.000799 eV | 0.00075 eV | 105,106 |
| Roton Energy |  |  |  |

Helium, exhibits unique behavior due to its possible phases based on the interplay of the factors that determine the van der Waals bonding at a given temperature and pressure to achieve an energy minimum. In extreme cases of sufficient ultra-low temperatures with the atoms driven in phase with an external excitation field such that the formation of a van der Waals-dipolebound macromolecular state or other forms of bonding, such as metallic bonding in the case of alkali metals or van der Waals bonding in meta-stable helium atoms, are suppressed, a pure statistical thermodynamic state called a Bose-Einstein condensate [109] (BEC) $)^{1}$ can form having a predominant population of the atoms in a single, lowest-energy translational state in the trap. Since helium has only two electrons in an outer s-shell having a small diameter, the dipole moment is too weak to form transverse dipoles associated with packing. Specifically, with the angular dependence of packed dipoles interactions, the van der Waals energy $E_{\text {van der Waals }}(\mathrm{He})$ (Eqs. (16.98) and (16.99)) between neighboring dipoles becomes less than the vibrational energy in the transition state ( $\bar{E}_{\text {Kvib }}$ term of Eq. (16.99) from Eq. (15.53)). Consequently, helium can only mutually induce and form linear dipole-dipole bonds having end-to-end interactions as an energy minimum. Interposed atoms can form a non-bonded phase having correlated translational motion and obeying Bose-Einstein statistics. This phase forms a Bose-Einstein condensate (BEC) as an energy minimum wherein the translations are synchronous. Since a phase comprised of linearly ordered unit cells held together by dipole interactions, specifically van der Waals dipole interactions, can exist with a BEC phase, super-fluidity can arise wherein the lines of bound dipoles move without friction relative to the BEC phase having correlated-translational motion. The linear bonding is also the origin of quantized vortex rings that enter as quantized vortex lines to form rings.

The van der Waals bonds undergo breakage and formation and exist on a time-average basis depending on the internal energy and pressure as in the case of liquid water. The van der Waals bonding exhibits a maximum extent as the temperature is lowered below the boiling point, and the BEC phase comprises the balance of the atoms as the temperature is further lowered to absolute zero. Helium cannot form a solid without application of high pressure to decrease the interatomic separation and permit energetically favorable transverse dipole interactions as well as linear ones. In contrast, other noble gases such as $\mathrm{Ne}, \mathrm{Ar}, \mathrm{Kr}$, and $X e$ each possess additional shells including an outer p -shell having a relatively larger radius that gives rise to a significant bond moment supportive of dipole packing interactions; thus, these gases can form solids without the application of high pressure.

## GEOMETRICAL PARAMETERS AND ENERGIES DUE TO THE INTERATOMIC VAN DER WAALS COHESIVE ENERGY OF SOLID NEON

Neon is a ten-electron neutral atom having the electron configuration $1 s^{2} 2 s^{2} 2 p^{6}$ with the electrons of each shell paired as mirror-image current densities in a shell wherein the radius of the outer shell is $r_{10}=0.63659 a_{0}$ (Eq. (10.202)). Thus, in isolation or at sufficient separation, there is no energy between neon atoms. However, reversible mutual van der Waals dipoles may be induced by collisions when the atoms are in close proximity such that neon gas can condense into a liquid and further solidify at sufficiently low temperatures due to the strong dipole moment that accommodates close packing. As in the case of helium, the dipoles are atomic rather than molecular, and the limiting separation is based on the formation of a nascent bond to replace the dipole-dipole interaction. Thus, Eq. (16.25) can also be applied to neon atoms.

The van der Waals bonding in the neon atom involves hybridizing the three $2 p$ AOs into $2 p^{3} \mathrm{HO}$ orbitals containing six electrons. The total energy of the state is given by the sum over the six electrons. The sum $E_{T}\left(N e, 2 p^{3}\right)$ of experimental energies [15] of $\mathrm{Ne}, \mathrm{Ne} e^{+}, N e^{2+}, N e^{3+}, N e^{4+}$, and $N e^{5+}$ is

[^43]\[

$$
\begin{equation*}
E_{T}\left(N e, 2 p^{3}\right)=\binom{157.93 \mathrm{eV}+126.21 \mathrm{eV}+97.12 \mathrm{eV}}{+63.45 \mathrm{eV}+40.96296 \mathrm{eV}+21.56454 \mathrm{eV}}=507.2375 \mathrm{eV} \tag{16.109}
\end{equation*}
$$

\]

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{2 p^{3}}$ of the $N e 2 p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{2 p^{3}}=\sum_{n=4}^{9} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 507.2375 \mathrm{eV})}=\frac{21 e^{2}}{8 \pi \varepsilon_{0}(e 507.2375 \mathrm{eV})}=0.56329 a_{0} \tag{16.110}
\end{equation*}
$$

where $Z=10$ for neon. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(N e, 2 p^{3}\right)$ of the outer electron of the van der Waals bound $N e 2 p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(N e, 2 p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{2 p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.56329 a_{0}}=-24.154167 \mathrm{eV} \tag{16.111}
\end{equation*}
$$

To meet the equipotential condition of the union of the two $N e 2 p^{3}$ HOs in a nascent bond, $c_{2}$ of Eqs. (15.2-15.5) and Eq. (15.61) for the nascent $N e-N e$-bond MO is given by Eq. (15.75) as the ratio of the valance energy of the Ne AO, $E(N e)=-21.56454 \mathrm{eV}$ and the magnitude of $E_{\text {Coulomb }}\left(N e, 2 p^{3}\right)$ (Eq. (16.111)).

$$
\begin{equation*}
c_{2}\left(\mathrm{Ne}-\mathrm{Ne}, \mathrm{Ne} 2 \mathrm{p}^{3} \mathrm{HO}\right)=\frac{21.56454 \mathrm{eV}}{24.154167 \mathrm{eV}}=0.89279 \tag{16.112}
\end{equation*}
$$

The opposite charge distributions act as symmetrical point charges at the point of maximum separation, each being centered at $1 / 2$ the $N e$-atom radius from the origin. Using the parameters of Eq. (16.112) and $2 c^{\prime}=0.56329 a_{0}=2.98080 \times 10^{-11} \mathrm{~m}$ (Eq. (16.110)), the van der Waals dipole of neon is given in Table 16.30.

Table 16.30. The parameters and van der Waals dipole bond moment of the $N e$ functional group of solid neon.

| Functional <br> Group | $n_{1}$ | $\left(c_{1}\right) c_{2}$ | $\left(C_{1}\right) C_{2}$ | $E_{B}($ valence $)$ | $E_{A}($ valence $)$ | $\frac{q}{e}$ | Bond <br> Length <br> $2 c^{\prime}(A)$ | Bond <br> Moment <br> $\mu(\mathrm{D})$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Ne | 1 | 0.89279 | 1 | 21.56454 | 24.15417 | 0.22730 | 0.298080 | 0.32544 |

The minimum-energy packing of neon dipoles is face-centered cubic also called cubic close packing. In this case, each neon atom has 12 nearest neighbors and the angle between the aligned dipoles is $\frac{\pi}{4}$ radians. As in the case with graphite, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{N e}=0.32544 D=1.08554 \times 10^{-30} \mathrm{C} \cdot \mathrm{m}$ (Table 16.30), the van der Waals energy is:

$$
\begin{equation*}
E_{\text {van der Waals }}(N e)=12 \frac{2\left(\mu_{N e}\right)^{2}}{4 \pi \varepsilon_{0}\left(r_{\text {Ne....Ne }}\right)^{3}} \cos \left(\frac{\pi}{4}\right)=\left(\frac{24\left(1.08554 X 10^{-30} C \cdot m\right)^{2}}{4 \pi \varepsilon_{0}\left(2 \sqrt{\frac{a_{N e . . N e} a_{0}}{2 C_{1} C_{2}}}\right)^{3}}\right) \cos \left(\frac{\pi}{4}\right) \tag{16.113}
\end{equation*}
$$

The neon interatomic distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.113)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter $c_{2}$ is the same as that of the neon dipole, and the reduced mass is $\mu=10$. The parameters are summarized in Table 16.31 and Eq. (16.114).

Table 16.31. The energy parameters $(e V)$ of the neon functional group ( $N e \cdots N e$ ).

| Parameters | $\begin{aligned} & N e \cdots N e \\ & \text { Group } \end{aligned}$ |
| :---: | :---: |
| $n_{1}$ | 1 |
| $C_{1}$ | 0.5 |
| $\mathrm{C}_{2}$ | $0.89279{ }^{-1}$ |
| $c_{1}$ | 1 |
| $c_{2}$ | 0.89279 |
| $C_{10}$ | 0.5 |
| $C_{2 o}$ | $0.89279^{-1}$ |
| $V_{e}(\mathrm{eV})$ | -4.40464 |
| $V_{p}(e \mathrm{~V})$ | 4.27694 |
| $T(e V)$ | 0.19429 |
| $V_{m}(\mathrm{eV})$ | -0.09714 |
| $E$ (Ао/но) (eV) | 0 |
| $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}($ АО/НО) $(\mathrm{eV})$ | 0 |
| $E_{T}($ Ао/но) $)(\mathrm{eV})$ | 0 |
| $E_{T}\left(\mathrm{H}_{2} \mathrm{MO}\right)(\mathrm{eV})$ | -0.03055 |
| $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} \cdot \mathrm{AO}\right)(\mathrm{eV})$ | 0 |
| $E_{T}($ мо $)(\mathrm{eV})$ | -0.03055 |
| $\omega\left(10^{15} \mathrm{rad} / \mathrm{s}\right)$ | 0.810674 |
| $E_{K}(e V)$ | 0.53360 |
| $\bar{E}_{D}(e V)$ | -0.00004 |
| $\bar{E}_{\text {Kvib }}(e \mathrm{~V})$ | 0.00240 |
| $\bar{E}_{\text {osc }}(\mathrm{eV})$ | 0.00116 |
| $E_{T}($ Group $)(e V)$ | -0.02939 |

Substitution of the parameters of Table 16.31 and the interatomic cohesive energy of neon (Eq. (16.113)) into Eq. (16.25) with $R=a_{N e . . N e}$ gives:

$$
\frac{-24\left(1.08554 \times 10^{-30} C \cdot m\right)^{2}}{4 \pi \varepsilon_{0}\left(2 \sqrt{\frac{a_{\text {Ne...Ne }} a_{0}}{2(0.5)(0.89279)^{-1}}}\right)^{3}} \cos \left(\frac{\pi}{4}\right)
$$

From the energy relationship given by Eq. (16.114) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $N e \cdots N e$ MO can be solved.

The most convenient way to solve Eq. (16.114) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a_{N e \cdots N e}=11.33530 a_{0}=5.99838 \times 10^{-10} \mathrm{~m} \tag{16.115}
\end{equation*}
$$

The component energy parameters at this condition are given in Table 16.31. Substitution of Eq. (16.115) into Eq. (16.22) gives

$$
\begin{equation*}
c_{N e \cdots N e}^{\prime}=3.18120 a_{0}=1.68342 \times 10^{-10} \mathrm{~m} \tag{16.116}
\end{equation*}
$$

and internuclear distance between neighboring neon atoms:

$$
\begin{equation*}
2 c_{N e . . N e}^{\prime}=6.36239 a_{0}=3.36683 \times 10^{-10} \mathrm{~m}=3.36683 \AA \tag{16.117}
\end{equation*}
$$

The experimental neon interatomic distance $2 c_{C \ldots C}^{\prime}$ at the melting point of 24.48 K is [112, 113]:

$$
\begin{equation*}
2 c_{N e \cdots N e}^{\prime}(24.48 \mathrm{~K})=3.21 \times 10^{-10} \mathrm{~m}=3.21 \AA \tag{16.118}
\end{equation*}
$$

The other interatomic bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.115) and (16.116) into Eq. (16.23) gives:

$$
\begin{equation*}
b_{N e \cdots N e}=c_{N e . . N e}=10.87975 a_{0}=5.75732 \times 10^{-10} \mathrm{~m} \tag{16.119}
\end{equation*}
$$

Substitution of Eqs. (16.115) and (16.116) into Eq. (16.25) gives:

$$
\begin{equation*}
e_{N e . . N e}=0.28065 \tag{16.120}
\end{equation*}
$$

A convenient method to calculate the lattice energy is to determine the electric field in solid neon having an electric polarization density corresponding to the aligned dipoles moments, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic form of Gauss' equation. Substitution of the density of solid neon at the melting point $\rho=\frac{1.433 \mathrm{~g}}{1 \times 10^{-6} \mathrm{~m}^{3}}$ [113], the $M W=20.179 \mathrm{~g} /$ mole, $N_{A}=6.0221415 \times 10^{23}$ molecules / mole, and the neon dipole moment given in Table 16.30 into Eq. (16.53) gives:

$$
\begin{align*}
U(N e) & =\frac{-2\left(\mu_{N e}\right)^{2} \frac{\rho_{\text {solid Ne }}}{M W} N_{A}}{3 \varepsilon_{0}}=\frac{-2\left(1.08554 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m}\right)^{2} \frac{\frac{1.433 \mathrm{~g}}{1 \times 10^{-6} \mathrm{~m}^{3}}}{20.179 \mathrm{~g} / \mathrm{mole}} 6.0221415 \times 10^{23} \text { molecules / mole }}{3 \varepsilon_{0}}  \tag{16.121}\\
& =-0.02368 \mathrm{eV}(-2.285 \mathrm{~kJ} / \text { mole })
\end{align*}
$$

$U(N e)$ is also the negative of $E_{\text {van der Waals }}$, the van der Waals energy per neon atom:

$$
\begin{equation*}
E_{\text {van der Waals }}(\text { solid } \mathrm{Ne} / \mathrm{Ne})=0.02368 \mathrm{eV}=2.285 \mathrm{~kJ} / \text { mole } \tag{16.122}
\end{equation*}
$$

The experimental van der Waals energy calculated from the heat of vaporization and fusion per neon atom at the boiling point and triple point, respectively, is [103] :

$$
\begin{equation*}
E_{\text {van der Waals }}(\text { solid Ne })=E_{\text {vapor }}+E_{\text {fusion }}=0.02125 \mathrm{eV} / \mathrm{Ne}=2.0502 \mathrm{~kJ} / \mathrm{mole} \tag{16.123}
\end{equation*}
$$

The calculated results based on first principles and given by analytical equations are summarized in Table 16.32. Using neon the atomic radius (Eq. (16.110)) and the nearest-neighbor distance (Eq. (16.117)), the lattice structure of neon is shown in Figure 16.17A. The charge density of the van der Waals dipoles of the crystalline lattice is shown in Figure 16.18A.

Table 16.32. The calculated and experimental geometrical parameters and interatomic van der Waals cohesive energy of solid neon.

| Parameter | Calculated | Experimental | Ref. for Exp. |
| :--- | :---: | :---: | :---: |
| Solid Neon Interatomic Distance $2 c_{C \ldots C}^{\prime}$ | $3.36683 \AA$ | $3.21 \AA(\mathrm{~T}=24.48 \mathrm{~K})$ | 113 |
| van der Waals Energy per Neon Atom | 0.02368 eV | 0.02125 eV | 103 |

## GEOMETRICAL PARAMETERS AND ENERGIES DUE TO THE INTERATOMIC VAN DER WAALS COHESIVE ENERGY OF SOLID ARGON

Argon is an eighteen-electron neutral atom having the electron configuration $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6}$ with the electrons of each shell paired as mirror-image current densities in a shell wherein the radius of the outer shell is $r_{18}=0.86680 a_{0}$ (Eq. (10.386)). Thus, in isolation or at sufficient separation, there is no energy between argon atoms. However, reversible mutual van der Waals dipoles may be induced by collisions when the atoms are in close proximity such that argon gas can condense into a liquid and further solidify at sufficiently low temperatures due to the strong dipole moment that accommodates close packing. As in the case of helium, the dipoles are atomic rather than molecular, and the limiting separation is based on the formation of a nascent bond to replace the dipole-dipole interaction. Thus, Eq. (16.25) can also be applied to argon atoms.

The van der Waals bonding in the argon atom involves hybridizing the three $3 p$ AOs into $3 p^{3} \mathrm{HO}$ orbitals containing six electrons. The total energy of the state is given by the sum over the six electrons. The sum $E_{T}\left(A r, 3 p^{3}\right)$ of experimental energies [15] of $A r, A r^{+}, A r^{2+}, A r^{3+}, A r^{4+}$, and $A r^{5+}$ is:

$$
\begin{equation*}
E_{T}\left(A r, 3 p^{3}\right)=\binom{91.009 \mathrm{eV}+75.02 \mathrm{eV}+59.81 \mathrm{eV}}{+40.74 \mathrm{eV}+27.62966 \mathrm{eV}+15.75961 \mathrm{eV}}=309.96827 \mathrm{eV} \tag{16.124}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 p^{3}}$ of the $\operatorname{Ar} 3 p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{3 p^{3}}=\sum_{n=12}^{17} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 309.96827 \mathrm{eV})}=\frac{21 e^{2}}{8 \pi \varepsilon_{0}(e 309.96827 \mathrm{eV})}=0.92178 a_{0} \tag{16.125}
\end{equation*}
$$

where $Z=18$ for argon. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(A r, 3 p^{3}\right)$ of the outer electron of the van der Waals bound $\operatorname{Ar} 3 p^{3}$ shell is

$$
\begin{equation*}
E_{\text {Coulomb }}\left(A r, 3 p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.92178 a_{0}}=-14.760394 \mathrm{eV} \tag{16.126}
\end{equation*}
$$

To meet the equipotential condition of the union of the two $\operatorname{Ar} 3 p^{3}$ HOs in a nascent bond, $c_{2}$ of Eqs. (15.2-15.5) and Eq. (15.61) for the nascent $A r-A r$-bond MO is given by Eq. (15.75) as the ratio of the valance energy of the $A r$ AO, $E(A r)=-15.75961 \mathrm{eV}$ and the magnitude of $E_{\text {Coulomb }}\left(A r, 3 p^{3}\right)$ (Eq. (16.126)).

$$
\begin{equation*}
c_{2}\left(A r-A r, A r 3 p^{3} \mathrm{HO}\right)=\frac{14.760394 \mathrm{eV}}{15.75961 \mathrm{eV}}=0.93660 \tag{16.127}
\end{equation*}
$$

Since the outer $\operatorname{Ar} 3 p^{3} \mathrm{HO}$ shell is at a lower energy and greater radius than the non-polarized $3 p$ shell, the inner shells are polarized as well. The dipole of the outer shell can polarize the inner shells to the limit that the sum of the primary and secondary dipoles is twice the primary scaled by the energy matching factors of the van der Waals bond given in Eq. (16.15). Thus, the limiting dipole due to polarization of the inner shells is given by:

$$
\begin{align*}
\mu_{A r}<2 c_{1}^{-1} q C_{2} 2 c^{\prime} & =2(0.93660)^{-1}(0.13110) e(0.93660)^{-1}\left(4.87784 \times 10^{-11} \mathrm{~m}\right)  \tag{16.128}\\
& =2.49410 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m}=0.74771 \mathrm{D}
\end{align*}
$$

The condition of Eq. (16.128) is matched by the participation of the outer four shells as given in Table 16.33. At each shell, opposite charge distributions act as symmetrical point charges at the point of maximum separation, each being centered at $1 / 2$ the shell radius from the origin. Using the parameters of Eq. (16.127) and $2 c^{\prime}=0.92178 a_{0}=4.87784 \times 10^{-11} \mathrm{~m}$ (Eq. (16.125)) as well as the radii of the inner shells of argon (Table 10.17), the van der Waals dipole of argon is given in Table 16.33 as the sum of the moments of each participating shell.

Table 16.33. The parameters and van der Waals dipole bond moment of the $A r$ functional group of solid argon.

| Functional <br> Group | $n_{1}$ | $\left(c_{1}\right)$ <br> $c_{2}$ | $\left(C_{1}\right)$ <br> $C_{2}$ | $E_{B}$ (valence) | $E_{A}($ valence $)$ | $\frac{q}{e}$ | Bond <br> Length $2 c^{\prime}(A)$ | Bond <br> Moment <br> $\mu(\mathrm{D})$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $A r$ | 1 | 0.93660 | 1 | 14.76039 | 15.75961 | 0.13110 | $\operatorname{Ar} 3 p^{3} \mathrm{HO} 0.48778$ <br> $\operatorname{Ar} 3 s$ AO 0.41422 <br> $A r 2 p$ AO 0.15282 <br> $A r 2 s$ AO 0.12615 | 0.74366 |

The minimum-energy packing of argon dipoles is face-centered cubic also called cubic close packing. In this case, each argon atom has 12 nearest neighbors and the angle between the aligned dipoles is $\frac{\pi}{4}$ radians. As in the case with graphite, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{A r}=0.74366 D=2.48058 \times 10^{-30} \mathrm{C} \cdot \mathrm{m}$ (Table 16.33), the van der Waals energy is:

$$
\begin{equation*}
E_{\text {van der Waals }}(A r)=12 \frac{2\left(\mu_{A r}\right)^{2}}{4 \pi \varepsilon_{0}\left(r_{A r \ldots A r}\right)^{3}} \cos \left(\frac{\pi}{4}\right)=\left(\frac{24\left(2.48058 X 10^{-30} C \cdot m\right)^{2}}{4 \pi \varepsilon_{0}\left(2 \sqrt{\frac{a_{A r \ldots A r} a_{0}}{2 C_{1} C_{2}}}\right)^{3}}\right) \cos \left(\frac{\pi}{4}\right) \tag{16.129}
\end{equation*}
$$

The argon interatomic distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.129)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter $c_{2}$ is the same as that of the argon dipole, and the reduced mass is $\mu=20$. The parameters are summarized in Table 16.34 and Eq. (16.130).

Table 16.34. The energy parameters ( $e V$ ) of the argon functional group ( $A r \cdots A r$ ).

| Parameters | $A r \cdots A r$ Group |
| :---: | :---: |
| $n_{1}$ | 1 |
| $C_{1}$ | 0.5 |
| $\mathrm{C}_{2}$ | $0.93660^{-1}$ |
| $c_{1}$ | 1 |
| $c_{2}$ | 0.93660 |
| $C_{1 o}$ | 0.5 |
| $C_{2 o}$ | $0.93660^{-1}$ |
| $V_{e}(e \mathrm{~V})$ | -4.18356 |
| $V_{p}(e V)$ | 3.97600 |
| $T(e V)$ | 0.16731 |
| $V_{m}(\mathrm{eV})$ | -0.08365 |
| $E($ Ао/но) $(\mathrm{eV})$ | 0 |
| $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}($ Ао/но) $(\mathrm{eV})$ | 0 |
| $E_{T}$ ( (о/но) $(\mathrm{eV})$ | 0 |
| $E_{T}\left(\mathrm{H}_{2} \mathrm{MO}\right)(\mathrm{eV})$ | -0.12391 |
| $E_{T}\left(\right.$ atom - atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)(\mathrm{eV})$ | 0 |
| $E_{T}$ (мо) (eV) | -0.12391 |
| $\omega\left(10^{15} \mathrm{rad} / \mathrm{s}\right)$ | 0.683262 |
| $E_{K}(\mathrm{eV})$ | 0.44974 |
| $\bar{E}_{D}(\mathrm{eV})$ | -0.00016 |
| $\bar{E}_{\text {Kvib }}(e \mathrm{eV})$ | 0.00153 |
| $\bar{E}_{\text {osc }}(\mathrm{eV})$ | 0.00060 |
| $E_{T}$ (Group) (eV) | -0.12331 |

Substitution of the parameters of Table 16.34 and the interatomic cohesive energy of argon (Eq. (16.129)) into Eq. (16.25) with $R=a_{A r \ldots A r}$ gives:

$$
\frac{-24\left(2.48058 \times 10^{-30} C \cdot m\right)^{2}}{4 \pi \varepsilon_{0}\left(2 \sqrt{\frac{a_{A r . . A r} a_{0}}{2(0.5)(0.93660)^{-1}}}\right)^{3}} \cos \left(\frac{\pi}{4}\right)
$$

From the energy relationship given by Eq. (16.130) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $A r \cdots A r$ MO can be solved.

The most convenient way to solve Eq. (16.130) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a_{A r . . A r}=12.50271 a_{0}=6.61615 \times 10^{-10} \mathrm{~m} \tag{16.131}
\end{equation*}
$$

The component energy parameters at this condition are given in Table 16.34. Substitution of Eq. (16.131) into Eq. (16.22) gives

$$
\begin{equation*}
c_{A r \cdots A r}^{\prime}=3.42199 a_{0}=1.81084 \times 10^{-10} \mathrm{~m} \tag{16.132}
\end{equation*}
$$

and internuclear distance between neighboring argon atoms:

$$
\begin{equation*}
2 c_{A r \cdots A r}^{\prime}(0 K)=6.84397 a_{0}=3.62167 \times 10^{-10} m=3.62167 \AA \tag{16.133}
\end{equation*}
$$

The experimental argon interatomic distance $2 c_{C \ldots C}^{\prime}$ is [114]

$$
\begin{equation*}
2 c_{A r \cdots A r}^{\prime}(4.2 K)=3.71 \times 10^{-10} \mathrm{~m}=3.71 \AA \tag{16.134}
\end{equation*}
$$

The other interatomic bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.131) and (16.132) into Eq. (16.23) gives:

$$
\begin{equation*}
b_{A r \ldots A r}=c_{A r \ldots A r}=12.02530 a_{0}=6.36351 \times 10^{-10} \mathrm{~m} \tag{16.135}
\end{equation*}
$$

Substitution of Eqs. (16.131) and (16.132) into Eq. (16.25) gives:

$$
\begin{equation*}
e_{A r \ldots A r}=0.27370 \tag{16.136}
\end{equation*}
$$

A convenient method to calculate the lattice energy is to determine the electric field in solid argon having an electric polarization density corresponding to the aligned dipoles moments, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic form of Gauss' equation. Substitution of the density of solid argon at $4.2 \mathrm{~K} \rho=\frac{1.83 \mathrm{~g}}{1 \times 10^{-6} \mathrm{~m}^{3}}$ [114], the $M W=39.948 \mathrm{~g} /$ mole, $N_{A}=6.0221415 \times 10^{23}$ molecules / mole, and the argon dipole moment given in Table 16.33 into Eq. (16.53) gives:

$$
\begin{align*}
U(A r) & =\frac{-2\left(\mu_{A r}\right)^{2} \frac{\rho_{\text {solid } A r}}{M W} N_{A}}{3 \varepsilon_{0}} \\
& =\frac{-2\left(2.48058 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m}\right)^{2} \frac{\frac{1.83 \mathrm{~g}}{1 \times 10^{-6} \mathrm{~m}^{3}}}{39.948 \mathrm{~g} / \mathrm{mole}^{2}} 6.0221415 \times 10^{23} \text { molecules / mole }}{3 \varepsilon_{0}}  \tag{16.137}\\
& =-0.07977 \mathrm{eV}(-7.697 \mathrm{~kJ} / \text { mole })
\end{align*}
$$

$U(A r)$ is also the negative of $E_{\text {van der Waals }}$, the van der Waals energy per argon atom:

$$
\begin{equation*}
E_{\text {van der Waals }}(\text { solid } \mathrm{Ar}, 4.2 \mathrm{~K} / \mathrm{Ar})=0.07977 \mathrm{eV}=7.697 \mathrm{~kJ} / \text { mole } \tag{16.138}
\end{equation*}
$$

The experimental van der Waals energy is the cohesive energy [115]:

$$
\begin{equation*}
E_{\text {van der Waals }}(\text { solid } \mathrm{Ar}, 0 \mathrm{~K})=0.08022 \mathrm{eV} / \mathrm{Ar}=7.74 \mathrm{~kJ} / \text { mole } \tag{16.139}
\end{equation*}
$$

The calculated results based on first principles and given by analytical equations are summarized in Table 16.35. Using argon the atomic radius (Eq. (16.125)) and the nearest-neighbor distance (Eq. (16.133)), the lattice structure of argon is shown in Figure 16.17B. The charge density of the van der Waals dipoles of the crystalline lattice is shown in Figure 16.18B.

Table 16.35. The calculated and experimental geometrical parameters and interatomic van der Waals cohesive energy of solid argon.

| Parameter | Calculated | Experimental | Ref. for Exp. |
| :--- | :---: | :---: | :---: |
| Solid Argon Interatomic Distance $2 c_{C \ldots C}^{\prime}$ | $3.62167 \AA(\mathrm{~T}=0 \mathrm{~K})$ | $3.71 \AA(\mathrm{~T}=4.2 \mathrm{~K})$ | 114 |
| van der Waals Energy per Argon Atom | $0.07977 \mathrm{eV}(\mathrm{T}=4.2 \mathrm{~K})$ | $0.08022 \mathrm{eV}(\mathrm{T}=0 \mathrm{~K})$ | 115 |

## GEOMETRICAL PARAMETERS AND ENERGIES DUE TO THE INTERATOMIC VAN DER WAALS COHESIVE ENERGY OF SOLID KRYPTON

Krypton is a thirty-six-electron neutral atom having the electron configuration $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 3 d^{10} 4 s^{2} 4 p^{6}$ with the electrons of each shell paired as mirror-image current densities in a shell wherein the radius of the outer shell is $r_{36}=0.97187 a_{0}$ (Eq. (10.102)). Thus, in isolation or at sufficient separation, there is no energy between krypton atoms. However, reversible mutual van der Waals dipoles may be induced by collisions when the atoms are in close proximity such that krypton gas can condense into a liquid and further solidify at sufficiently low temperatures due to the strong dipole moment that accommodates close packing. As in the case of helium, the dipoles are atomic rather than molecular, and the limiting separation is based on the formation of a nascent bond to replace the dipole-dipole interaction. Thus, Eq. (16.25) can also be applied to krypton atoms.

The van der Waals bonding in the krypton atom involves hybridizing the three $4 p$ AOs into $4 p^{3} \mathrm{HO}$ orbitals containing six electrons. The total energy of the state is given by the sum over the six electrons. The sum $E_{T}\left(K r, 4 p^{3}\right)$ of experimental energies $[15,116-119]$ of $\mathrm{Kr}, \mathrm{Kr}^{+}, \mathrm{Kr}^{2+}, \mathrm{Kr}^{3+}, \mathrm{Kr}^{4+}$, and $\mathrm{Kr}^{5+}$ is:

$$
\begin{equation*}
E_{T}\left(K r, 4 p^{3}\right)=\binom{78.5 \mathrm{eV}+64.7 \mathrm{eV}+52.5 \mathrm{eV}}{+36.950 \mathrm{eV}+24.35984 \mathrm{eV}+13.99961 \mathrm{eV}}=271.00945 \mathrm{eV} \tag{16.140}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{4 p^{3}}$ of the $K r 4 p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{4 p^{3}}=\sum_{n=30}^{35} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 271.00945 \mathrm{eV})}=\frac{21 e^{2}}{8 \pi \varepsilon_{0}(e 271.00945 \mathrm{eV})}=1.05429 a_{0} \tag{16.141}
\end{equation*}
$$

where $Z=36$ for krypton. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(K r, 4 p^{3}\right)$ of the outer electron of the van der Waals bound $K r 4 p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(K r, 4 p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{4 p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.05429 a_{0}}=-12.905212 \mathrm{eV} \tag{16.142}
\end{equation*}
$$

To meet the equipotential condition of the union of the two $K r 4 p^{3}$ HOs in a nascent bond, $c_{2}$ of Eqs. (15.2-15.5) and Eq. (15.61) for the nascent $K r-K r$-bond MO is given by Eq. (15.75) as the ratio of the valance energy of the $K r \mathrm{AO}$, $E(K r)=-13.99961 \mathrm{eV}$ and the magnitude of $E_{\text {Coulomb }}\left(K r, 4 p^{3}\right)$ (Eq. (16.142)).

$$
\begin{equation*}
c_{2}\left(K r-K r, K r 4 p^{3} H O\right)=\frac{12.905212 \mathrm{eV}}{13.99961 \mathrm{eV}}=0.92183 \tag{16.143}
\end{equation*}
$$

Since the outer $\operatorname{Kr} 4 p^{3} \mathrm{HO}$ shell is at a lower energy and greater radius than the non-polarized $4 p$ shell, the inner shells are polarized as well. The dipole of the outer shell can polarize the inner shells to the limit that the sum of the primary and secondary dipoles is twice the primary scaled by the energy matching factors of the van der Waals bond given in Eq. (16.15). Thus, the limiting dipole due to polarization of the inner shells is given by:

$$
\begin{align*}
\mu_{K r}<2 c_{1}^{-1} q C_{2} 2 c^{\prime} & =2(0.16298) e(0.92183)^{-1}\left(5.57905 \times 10^{-11} \mathrm{~m}\right)  \tag{16.144}\\
& =3.42870 \times 10^{-30} C \cdot m=1.02790 D
\end{align*}
$$

The condition of Eq. (16.144) is matched by the participation of the outer three shells as given in Table 16.36. At each shell, opposite charge distributions act as symmetrical point charges at the point of maximum separation, each being centered at $1 / 2$ the shell radius from the origin. Using the parameters of Eq. (16.143) and $2 c^{\prime}=1.05429 a_{0}=5.57905 \times 10^{-11} \mathrm{~m}$ (Eq. (16.141))
as well as the radii of the inner shells of krypton (Eq. (10.102)), the van der Waals dipole of krypton is given in Table 16.36 as the sum of the moments of each participating shell.

Table 16.36. The parameters and van der Waals dipole bond moment of the $K r$ functional group (FG) of solid krypton.

| FG | $n_{1}$ | $\left(c_{1}\right)$ <br> $c_{2}$ | $\left(C_{1}\right)$ <br> $C_{2}$ | $E_{B}($ valence $)$ | $E_{A}$ (valence) | $\frac{q}{e}$ | Ion $/$ IP $/ Z$ <br> $[116-119]$ | Bond <br> Length <br> $2 c^{\prime}(A)$ | Bond <br> Moment <br> $\mu$ (D) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $K r$ | 1 | 0.92183 | 1 | 12.90521 | 13.99961 | 0.16298 |  | (Eqs. (16.141) <br> and (10.102)) |  |

The minimum-energy packing of krypton dipoles is face-centered cubic also called cubic close packing. In this case, each krypton atom has 12 nearest neighbors and the angle between the aligned dipoles is $\frac{\pi}{4}$ radians. As in the case with graphite, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{K r}=1.01129 D=3.37329 \times 10^{-30} \mathrm{C} \cdot \mathrm{m}$ (Table 16.36), the van der Waals energy is:

$$
\begin{equation*}
E_{\text {van der Waals }}(K r)=12 \frac{2\left(\mu_{K r}\right)^{2}}{4 \pi \varepsilon_{0}\left(r_{K r . . . K r}\right)^{3}} \cos \left(\frac{\pi}{4}\right)=\left(\frac{24\left(3.37329 X 10^{-30} C \cdot m\right)^{2}}{4 \pi \varepsilon_{0}\left(2 \sqrt{\frac{a_{K r \ldots K r} a_{0}}{2 C_{1} C_{2}}}\right)^{3}}\right) \cos \left(\frac{\pi}{4}\right) \tag{16.145}
\end{equation*}
$$

The krypton interatomic distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.145)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter $c_{2}$ is the same as that of the krypton dipole, and the reduced mass is $\mu=42$. The parameters are summarized in Table 16.37 and Eq. (16.146).

Table 16.37. The energy parameters $(\mathrm{eV})$ of the krypton functional group ( $K r \cdots K r$ ).

| Parameters | $K r \cdots K r$ <br> Group |
| :---: | :---: |
| $n_{1}$ | 1 |
| $C_{1}$ | 0.5 |
| $\mathrm{C}_{2}$ | 0.92183 |
| $c_{1}$ | 1 |
| $c_{2}$ | 0.92183 |
| $C_{10}$ | 0.5 |
| $C_{2 o}$ | 0.92183 |
| $V_{e}(\mathrm{eV})$ | -3.75058 |
| $V_{p}(e V)$ | 3.52342 |
| $T(\mathrm{eV})$ | 0.13643 |
| $V_{m}(\mathrm{eV})$ | -0.06821 |
| $E($ Ао/но) $($ eV) | 0 |
| $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}($ Ао/ $/ \mathrm{HO})(\mathrm{eV})$ | 0 |
| $E_{T}$ (Ао/но) $(\mathrm{eV})$ | 0 |
| $E_{T}\left(\mathrm{H}_{2} \mathrm{MO}\right)(\mathrm{eV})$ | -0.15895 |
| $E_{T}\left(\right.$ atom - atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)(\mathrm{eV})$ | 0 |
| $E_{T}($ мо $)(\mathrm{eV})$ | -0.15895 |
| $\omega\left(10^{15} \mathrm{rad} / \mathrm{s}\right)$ | 0.550731 |
| $E_{K}(\mathrm{eV})$ | 0.36250 |
| $\bar{E}_{D}(\mathrm{eV})$ | -0.00019 |
| $\bar{E}_{\text {Kvib }}(\mathrm{eV})$ | 0.00091 |
| $\bar{E}_{\text {osc }}(\mathrm{eV})$ | 0.00026 |
| $E_{T}($ Group $)(\mathrm{eV})$ | -0.15869 |

Substitution of the parameters of Table 16.37 and the interatomic cohesive energy of krypton (Eq. (16.145)) into Eq. (16.25) with $R=a_{K r . . . K r}$ gives:

$$
\frac{-24\left(3.37329 \times 10^{-31} C \cdot m\right)^{2}}{4 \pi \varepsilon_{0}\left(2 \sqrt{\frac{a_{K r \cdot K r} a_{0}}{2(0.5)(0.92183)}}\right)^{3}} \cos \left(\frac{\pi}{4}\right)
$$

From the energy relationship given by Eq. (16.146) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $K r \cdots K r$ MO can be solved.

The most convenient way to solve Eq. (16.146) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a_{K r \cdots K r}=13.74580 a_{0}=7.27396 \times 10^{-10} \mathrm{~m} \tag{16.147}
\end{equation*}
$$

The component energy parameters at this condition are given in Table 16.37. Substitution of Eq. (16.147) into Eq. (16.22) gives

$$
\begin{equation*}
c_{K r \cdots K r}^{\prime}=3.86154 a_{0}=2.04344 \times 10^{-10} \mathrm{~m} \tag{16.148}
\end{equation*}
$$

and internuclear distance between neighboring krypton atoms:

$$
\begin{equation*}
2 c_{K r \ldots K r}^{\prime}(0 K)=7.72308 a_{0}=4.08688 \times 10^{-10} m=4.08688 \AA \tag{16.149}
\end{equation*}
$$

The experimental krypton interatomic distance $2 c_{C \ldots C}^{\prime}$ is [113]

$$
\begin{equation*}
2 c_{K r \cdots K r}^{\prime}(0 K)=3.992 \times 10^{-10} m=3.992 \not A \tag{16.150}
\end{equation*}
$$

The other interatomic bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.147) and (16.148) into Eq. (16.23) gives:

$$
\begin{equation*}
b_{K r \cdots K r}=c_{K r \cdots K r}=13.19225 a_{0}=6.98104 \times 10^{-10} \mathrm{~m} \tag{16.151}
\end{equation*}
$$

Substitution of Eqs. (16.147) and (16.148) into Eq. (16.25) gives:

$$
\begin{equation*}
e_{K r \cdots K r}=0.28092 \tag{16.152}
\end{equation*}
$$

A convenient method to calculate the lattice energy is to determine the electric field in solid krypton having an electric polarization density corresponding to the aligned dipoles moments, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic form of Gauss' equation. Substitution of the density of solid krypton at $4.2 \mathrm{~K} \rho=\frac{3.094 \mathrm{~g}}{1 \times 10^{-6} \mathrm{~m}^{3}}$ [113], the $M W=83.80 \mathrm{~g} /$ mole, $N_{A}=6.0221415 \times 10^{23}$ molecules / mole, and the krypton dipole moment given in Table 16.36 into Eq. (16.53) gives:

$$
\begin{align*}
U(K r) & =\frac{-2\left(\mu_{K r}\right)^{2} \frac{\rho_{\text {solid } K r}}{M W} N_{A}}{3 \varepsilon_{0}} \\
& =\frac{-2\left(3.37329 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m}\right)^{2} \frac{\frac{3.094 \mathrm{~g}}{1 \times 10^{-6} \mathrm{~m}^{3}}}{83.80 \mathrm{~g} / \mathrm{mole}} 6.0221415 \times 10^{23} \text { molecules / mole }}{3 \varepsilon_{0}}  \tag{16.153}\\
& =-0.11890 \mathrm{eV}(-11.472 \mathrm{~kJ} / \text { mole })
\end{align*}
$$

[ $U(K r)$ ] is also the negative of $E_{\text {van der Waals }}$, the van der Waals energy per krypton atom:

$$
\begin{equation*}
E_{\text {van der Waals }}(\text { solid } \mathrm{Kr}, 0 \mathrm{~K} / \mathrm{Kr})=0.11890 \mathrm{eV}=11.472 \mathrm{~kJ} / \text { mole } \tag{16.154}
\end{equation*}
$$

The experimental van der Waals energy is the cohesive energy [120]:

$$
\begin{equation*}
E_{\text {van der Waals }}(\text { solid } K r, 0 K / K r)=0.11561 \mathrm{eV}=11.15454 \mathrm{~kJ} / \text { mole } \tag{16.155}
\end{equation*}
$$

The calculated results based on first principles and given by analytical equations ( 0 K ) are summarized in Table 16.38. Using krypton the atomic radius (Eq. (16.141)) and the nearest-neighbor distance (Eq. (16.149)), the lattice structure of krypton is shown in Figure 16.15C. The charge density of the van der Waals dipoles of the crystalline lattice is shown in Figure 16.16C.

Table 16.38. The calculated and experimental geometrical parameters and interatomic van der Waals cohesive energy ( 0 K ) of solid krypton.

| $2 c_{C \ldots C}^{\prime}$ |  | 0.11890 eV | 0.11561 eV | 113 |  |
| van der Waals Energy per Krypton Atom |  | 120 |  |  |  |

## GEOMETRICAL PARAMETERS AND ENERGIES DUE TO THE INTERATOMIC VAN DER WAALS COHESIVE ENERGY OF SOLID XENON

Xenon is a fifty-four-electron neutral atom having the electron configuration $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 3 d^{10} 4 s^{2} 4 p^{6} 4 d^{10} 5 s^{2} 5 p^{6}$ with the electrons of each shell paired as mirror-image current densities in a shell wherein the radius of the outer shell is $r_{54}=1.12168 a_{0}$ (Eq. (10.102)). Thus, in isolation or at sufficient separation, there is no energy between xenon atoms. However, reversible mutual van der Waals dipoles may be induced by collisions when the atoms are in close proximity such that xenon gas can condense into a liquid and further solidify at sufficiently low temperatures due to the strong dipole moment that accommodates close packing. As in the case of helium, the dipoles are atomic rather than molecular, and the limiting separation is based on the formation of a nascent bond to replace the dipole-dipole interaction. Thus, Eq. (16.25) can also be applied to xenon atoms.

The van der Waals bonding in the xenon atom involves hybridizing the three $5 p$ AOs into $5 p^{3} \mathrm{HO}$ orbitals containing six electrons. The total energy of the state is given by the sum over the six electrons. The sum $E_{T}\left(X e, 5 p^{3}\right)$ of experimental energies $[15,121-122]$ of $\mathrm{Xe}, \mathrm{Xe} e^{+}, X e^{2+}, X e^{3+}, X e^{4+}$, and $X e^{5+}$ is:

$$
\begin{equation*}
E_{T}\left(X e, 5 p^{3}\right)=\binom{66.703 \mathrm{eV}+54.14 \mathrm{eV}+40.9 \mathrm{eV}}{+31.050 \mathrm{eV}+20.975 \mathrm{eV}+12.129842 \mathrm{eV}}=225.89784 \mathrm{eV} \tag{16.156}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{5 p^{3}}$ of the $X e 5 p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{5 p^{3}}=\sum_{n=48}^{53} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 225.897842 \mathrm{eV})}=\frac{21 e^{2}}{8 \pi \varepsilon_{0}(e 225.897842 \mathrm{eV})}=1.26483 a_{0} \tag{16.157}
\end{equation*}
$$

where $Z=54$ for xenon. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(X e, 5 p^{3}\right)$ of the outer electron of the van der Waals bound $X e 5 p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(X e, 5 p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{5 p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.26483 a_{0}}=-10.757040 \mathrm{eV} \tag{16.158}
\end{equation*}
$$

To meet the equipotential condition of the union of the two $X e 5 p^{3}$ HOs in a nascent bond, $c_{2}$ of Eqs. (15.2-15.5) and Eq. (15.61) for the nascent $X e-X e$-bond MO is given by Eq. (15.75) as the ratio of the valance energy of the $X e \mathrm{AO}$, $E(X e)=-12.129842 \mathrm{eV}$ and the magnitude of $E_{\text {Coulomb }}\left(X e, 5 p^{3}\right)$ (Eq. (16.158)).

$$
\begin{equation*}
c_{2}\left(X e-X e, X e 5 p^{3} H O\right)=\frac{10.75704 \mathrm{eV}}{12.129842 \mathrm{eV}}=0.88682 \tag{16.159}
\end{equation*}
$$

Since the outer $X e 5 p^{3} \mathrm{HO}$ shell is at a lower energy and greater radius than the non-polarized $5 p$ shell, the inner shells are polarized as well. The dipole of the outer shell can polarize the inner shells to the limit that the sum of the primary and secondary dipoles is twice the primary scaled by the energy matching factors of the van der Waals bond given in Eq. (16.15). Thus, the limiting dipole due to polarization of the inner shells is given by:

$$
\begin{equation*}
\mu_{X e}<2 c_{1}^{-1} q C_{2} 2 c^{\prime}=2(0.24079) e(0.88682)\left(6.69318 \times 10^{-11} \mathrm{~m}\right)=5.16444 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m}=1.54826 \mathrm{D} \tag{16.160}
\end{equation*}
$$

The condition of Eq. (16.160) is matched by the participation of the outer two shells as given in Table 16.39. At each shell, opposite charge distributions act as symmetrical point charges at the point of maximum separation, each being centered at $1 / 2$ the shell radius from the origin. Using the parameters of Eq. (16.159) and $2 c^{\prime}=1.26483 a_{0}=6.69318 \times 10^{-11} \mathrm{~m}$ (Eq. (16.157)) as well as the radius of the inner $5 s$ shell of xenon (Eq. (10.102)), the van der Waals dipole of xenon is given in Table 16.39 as the sum of the moments of each participating shell.

Table 16.39. The parameters and van der Waals dipole bond moment of the $X e$ functional group (FG) of solid xenon.

| FG | $n_{1}$ | $\begin{gathered} \left(c_{1}\right) \\ c_{2} \end{gathered}$ | $\begin{gathered} \left(C_{1}\right) \\ C_{2} \end{gathered}$ | $E_{B}$ (valence) | $E_{A}($ valence $)$ | $\frac{q}{e}$ | $\begin{gathered} \text { Ion / IP / Z } \\ {[121-122]} \end{gathered}$ | $\begin{aligned} & \text { Bond Length } \\ & 2 c^{\prime}(A) \\ & \text { (Eqs. }(16.157) \\ & \text { and }(10.102) \text { ) } \\ & \hline \end{aligned}$ | Bond Moment $\mu$ (D) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Xe | 1 | 0.88682 | 1 | 10.75704 | 12.12984 | 0.24079 |  | $\begin{gathered} X e 5 p^{3} \mathrm{HO} \\ 0.66932 \end{gathered}$ |  |
|  |  |  |  |  |  |  | $\begin{gathered} X e^{6+} \\ 91.6 \\ 7 \\ \hline \end{gathered}$ | $\begin{aligned} & X e 5 s \mathrm{AO} \\ & 0.55021 \end{aligned}$ | 1.41050 |

The minimum-energy packing of xenon dipoles is face-centered cubic also called cubic close packing. In this case, each xenon atom has 12 nearest neighbors and the angle between the aligned dipoles is $\frac{\pi}{4}$ radians. As in the case with graphite, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{X e}=1.41050 D=4.70492 \times 10^{-30} C \cdot m$ (Table 16.39), the van der Waals energy is:

$$
\begin{equation*}
E_{\text {van der Waals }}(X e)=12 \frac{2\left(\mu_{X e}\right)^{2}}{4 \pi \varepsilon_{0}\left(r_{X e . . . X e}\right)^{3}} \cos \left(\frac{\pi}{4}\right)=\left(\frac{24\left(4.70492 X 10^{-30} C \cdot m\right)^{2}}{4 \pi \varepsilon_{0}\left(2 \sqrt{\frac{a_{X e . . . X_{e}} a_{0}}{2 C_{1} C_{2}}}\right)^{3}}\right) \cos \left(\frac{\pi}{4}\right) \tag{16.161}
\end{equation*}
$$

The xenon interatomic distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.161)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter $c_{2}$ is the same that of the xenon dipole, and the reduced mass is $\mu=65$. The parameters are summarized in Table 16.40 and Eq. (16.162).

Table 16.40. The energy parameters $(e V)$ of the xenon functional group ( $X e \cdots X e$ ).

| Parameters | $X e \cdots X e$ Group |
| :---: | :---: |
| $n_{1}$ | 1 |
| $C_{1}$ | 0.5 |
| $\mathrm{C}_{2}$ | 0.88682 |
| $c_{1}$ | 1 |
| $c_{2}$ | 1 |
| $C_{10}$ | 0.5 |
| $C_{20}$ | 0.88682 |
| $V_{e}(\mathrm{eV})$ | -3.49612 |
| $V_{p}(e V)$ | 3.20821 |
| $T(e V)$ | 0.10960 |
| $V_{m}(e V)$ | -0.05480 |
| $E($ АоІно) (eV) | 0 |
| $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}($ АОІІ HO$)(\mathrm{eV})$ | 0 |
|  | 0 |
| $E_{T}\left(\mathrm{H}_{2} \mathrm{MO}\right)(\mathrm{eV})$ | -0.23311 |
| $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)(\mathrm{eV})$ | 0 |
| $E_{T}($ мо $)(\mathrm{eV})$ | -0.23311 |
| $\omega\left(10^{15} \mathrm{rad} / \mathrm{s}\right)$ | 0.432164 |
| $E_{K}(\mathrm{eV})$ | 0.28446 |
| $\bar{E}_{D}(e V)$ | -0.00025 |
| $\bar{E}_{\text {Kvib }}(\mathrm{eV})$ | 0.00062 |
| $\bar{E}_{\text {osc }}(\mathrm{eV})$ | 0.00006 |
| $E_{T}($ Group $)(\mathrm{eV})$ | -0.23305 |

Substitution of the parameters of Table 16.40 and the interatomic cohesive energy of xenon (Eq. (16.161)) into Eq. (16.25) with $R=a_{X e \ldots X e}$ gives:

$$
\frac{-24\left(4.70492 \times 10^{-31} C \cdot m\right)^{2}}{4 \pi \varepsilon_{0}\left(2 \sqrt{\frac{a_{X e-. X_{e}} a_{0}}{2(0.5)(0.88682)}}\right)^{3}} \cos \left(\frac{\pi}{4}\right)
$$

From the energy relationship given by Eq. (16.162) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $X e \cdots X e$ MO can be solved.

The most convenient way to solve Eq. (16.162) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a_{X e . . . X e}=15.94999 a_{0}=8.44037 \times 10^{-10} \mathrm{~m} \tag{16.163}
\end{equation*}
$$

The component energy parameters at this condition are given in Table 16.40. Substitution of Eq. (16.163) into Eq. (16.22) gives

$$
\begin{equation*}
c_{X e \cdots X e}^{\prime}=4.24093 a_{0}=2.24420 \times 10^{-10} \mathrm{~m} \tag{16.164}
\end{equation*}
$$

and internuclear distance between neighboring xenon atoms:

$$
\begin{equation*}
2 c_{X e \cdots X e}^{\prime}(0 K)=8.48187 a_{0}=4.48841 X 10^{-10} m=4.48841 \AA \tag{16.165}
\end{equation*}
$$

The experimental xenon interatomic distance $2 c_{C \ldots C}^{\prime}$ at the melting point of 161.35 K is [112, 113]:

$$
\begin{equation*}
2 c_{X e \cdots X e}^{\prime}(161.35 \mathrm{~K})=4.492 \times 10^{-10} \mathrm{~m}=4.492 \AA \tag{16.166}
\end{equation*}
$$

The other interatomic bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.163) and (16.164) into Eq. (16.23) gives:

$$
\begin{equation*}
b_{X e \cdots X e}=c_{X e \cdots X e}=15.37585 a_{0}=8.13655 \times 10^{-10} \mathrm{~m} \tag{16.167}
\end{equation*}
$$

Substitution of Eqs. (16.163) and (16.164) into Eq. (16.25) gives:

$$
\begin{equation*}
e_{X e \cdots X e}=0.26589 \tag{16.168}
\end{equation*}
$$

A convenient method to calculate the lattice energy is to determine the electric field in solid xenon having an electric polarization density corresponding to the aligned dipoles moments, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic form of Gauss' equation. Substitution of the density of solid xenon at $0 \mathrm{~K} \rho=\frac{3.780 \mathrm{~g}}{1 X 10^{-6} \mathrm{~m}^{3}}$ [113], the $M W=131.29 \mathrm{~g} /$ mole, $N_{A}=6.0221415 \times 10^{23}$ molecules $/ \mathrm{mole}$, and the xenon dipole moment given in Table 16.39 into Eq. (16.53) gives:

$$
\begin{align*}
U(X e) & =\frac{-2\left(\mu_{X e}\right)^{2} \frac{\rho_{\text {solid } X e}}{M W} N_{A}}{3 \varepsilon_{0}} \\
& =\frac{-2\left(4.70492 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m}\right)^{2} \frac{\frac{3.780 \mathrm{~g}}{1 \times 10^{-6} \mathrm{~m}^{3}}}{131.29 \mathrm{~g} / \mathrm{mole}} 6.0221415 \times 10^{23} \text { molecules / mole }}{3 \varepsilon_{0}}  \tag{16.169}\\
& =-0.18037 \mathrm{eV}(-17.403 \mathrm{~kJ} / \text { mole })
\end{align*}
$$

$U(X e)$ is also the negative of $E_{\text {van der Waals }}$, the van der Waals energy per xenon atom:

$$
\begin{equation*}
E_{\text {van der Waals }}(\text { solid } \mathrm{Xe}, 0 \mathrm{~K} / \mathrm{Xe})=0.18037 \mathrm{eV}=17.403 \mathrm{~kJ} / \text { mole } \tag{16.170}
\end{equation*}
$$

The experimental van der Waals energy is the cohesive energy [123]:

$$
\begin{equation*}
E_{\text {van der Waals }}(\text { solid Xe, } 0 \mathrm{~K})=0.16608 \mathrm{eV} / \mathrm{Xe}=16.02472 \mathrm{~kJ} / \text { mole } \tag{16.171}
\end{equation*}
$$

The calculated results based on first principles and given by analytical equations are summarized in Table 16.41. Using xenon the atomic radius (Eq. (16.157)) and the nearest-neighbor distance (Eq. (16.165)), the lattice structure of xenon is shown in Figure 16.15D. The charge density of the van der Waals dipoles of the crystalline lattice is shown in Figure 16.16D.

Table 16.41. The calculated and experimental geometrical parameters and interatomic van der Waals cohesive energy of solid xenon.

| Parameter | Calculated | Experimental | Ref. for Exp. |
| :--- | :---: | :---: | :---: |
| Solid Xenon Interatomic Distance $2 c_{C \ldots C}^{\prime}$ | $4.4884 \AA(\mathrm{~T}=0 \mathrm{~K})$ | $4.492 \AA(\mathrm{~T}=161.35 \mathrm{~K})$ | 113 |
| van der Waals Energy per Xenon Atom | 0.18037 eV | 0.16608 eV | 123 |
| $(0 \mathrm{~K})$ |  |  |  |

## REACTION KINETICS AND THERMODYNAMICS

Reaction kinetics may be modeled using the classical solutions of reacting species and their interactions during collisions wherein the bond order of the initial and final bonds undergo a decreasing and increasing bond order, respectively, with conservation of charge and energy. Collisions can be modeled starting with the simple hard sphere model with conservation of energy and momentum. The energy distribution may be modeled using the appropriate statistical thermodynamics model such as Maxwell-Boltzmann statistics. Low-energy collisions are elastic, but for sufficiently high energy, a reaction may occur. Hot reacting species such as molecules at the extreme of the kinetic energy distribution can achieve the transition state, the intermediate species at the cross over point in time and energy between the reactants and products. The rate function to form the transition state may depend on the collisional orientation as well as the collisional energy. Bond distortion conserves the energy and momentum of the collision from the trajectories of the reactants. For sufficient distortion due to a sufficiently energetic collision at an appropriate relative orientation, a reaction occurs wherein the products exiting the collision event are different from the reactants entering the collision. The initial reactant energy and momentum as well as those arising from any bonding energy changes are conserved in the translational, rotational, and vibrational energies of the products. The bond energy changes are given by the differences in the energies of the product and reactants molecules wherein the geometrical parameters, energies, and properties of the latter can be solved using the same equations as those used to solved the geometrical parameters and component energies of the individual molecules as given in the Organic Molecular Functional Groups and Molecules section. The bond energy changes at equilibrium determine the extent of a reaction according to the Gibbs free energy of reaction. Whereas, the corresponding dynamic reaction-trajectory parameters of translational, rotational, and vibrational energies as well as the time dependent electronic energy components such as the electron potential and kinetic energies of intermediates correspond to the reaction kinetics. Each aspect will be treated next in turn.

Consider the gas-phase reaction of two species $A$ and $B$ comprising the reactants that form one or more products $C_{n}$ where $n$ is an integer:

$$
\begin{equation*}
A+B \rightleftarrows C_{1}+\cdots+C_{n} \tag{16.172}
\end{equation*}
$$

Arising from collisional probabilities, the concentrations (denoted $[A],[B], \ldots$ ) as a function of time can be fitted to a secondorder rate law

$$
\begin{equation*}
-\frac{d[A]}{d t}=k[A][B]-k^{\prime} \prod_{i=1}^{n}\left[C_{i}\right] \tag{16.173}
\end{equation*}
$$

where $k$ and $k^{\prime}$ are the forward and reverse rate constants. The equilibrium constant $K$ corresponding to the balance between the forward and reverse reactions is given by the quotient of the forward and reverse rate constants:

$$
\begin{equation*}
K=\frac{k}{k^{\prime}} \tag{16.174}
\end{equation*}
$$

The relationship between the temperature-dependent equilibrium constant and the standard Gibbs free energy of reaction $\Delta G_{T}^{0}(T)$ at temperature $T$ is:

$$
\begin{equation*}
K=Q_{K}(T) e^{\frac{-\Delta G_{T}^{0}(T)}{R T}} \tag{16.175}
\end{equation*}
$$

where $R$ is the ideal gas constant,

$$
\begin{equation*}
Q_{K}(T)=\frac{\prod_{i=1}^{n}\left[C_{i}\right]}{[A][B]} \tag{16.176}
\end{equation*}
$$

is the reaction quotient at the standard state, and

$$
\begin{equation*}
\Delta G_{T}^{0}(T)=\Delta H_{T}^{0}(T)-T \Delta S_{T}^{0} \tag{16.177}
\end{equation*}
$$

where $\Delta H_{T}^{0}(T)$ and $\Delta S_{T}^{0}$ are the standard-state enthalpy and entropy of reaction, respectively. Rearranging Eq. (16.175) gives the free energy change upon reaction:

$$
\begin{equation*}
\Delta G=R T \ln \frac{Q_{K}}{K} \tag{16.178}
\end{equation*}
$$

If the instantaneous free energy change is zero, then the reaction is at equilibrium. An exergonic or work-producing reaction corresponds to the cases with $\Delta G_{T}^{0}(T)$ or $\Delta G$ negative, and endergonic or work consuming reactions corresponds to positive values. The enthalpy of reaction or heat of reaction at constant pressure is negative for an exothermic (heat releasing) reaction, and is positive for an endothermic (heat absorbing) reaction. The enthalpy of reaction may be calculated by Hess's law as the difference of the sum of the heats of formation of the products minus the sum of the heats of formation of the reactants wherein the individual heats of the molecules are solved using the equations given in the Organic Molecular Functional Groups and Molecules section.

## TRANSITION STATE THEORY

Transition state theory (TST) has been widely validated experimentally. It entails the application of classical trajectory calculations that allow the study of the dynamics at the microscopic level such as differential cross sections, total cross sections, and product energy distributions, as well as at the macroscopic level for the determination of thermal rate constants by solving the classical equations of motion with the formation of the transition state. The reaction trajectory parameters give rise to terms of a classical thermodynamic kinetics equation discovered in 1889 by Arrhenius and named after him. The data of the variation of the rate constant $k$ with temperature of many reactions fit the Arrhenius equation given by

$$
\begin{equation*}
k=A e^{\frac{-E_{a}}{R T}} \tag{16.179}
\end{equation*}
$$

where $E_{a}$ is the activation energy and $A$ is a preexponential or frequency factor that may have a relatively small temperature dependence compared to the exponential term of Eq. (16.179). For reactions that obey the Arrhenius equation, when $\ln k$ is plotted versus $1 / T$ in a so-called Arrhenius plot, the slope is the constant $-E_{a} / R$, and the intercept is $A$. Eq. (16.179) confirms that typically two colliding molecules require a certain minimum kinetic energy of relative motion to sufficiently distort initial reactant bonds and concomitantly allow nascent bonds to form. The crossover species from reactants to products called the transition state will proceed through the minimum energy complex involving the reactants. Thus, the activation energy can be interpreted as the minimum energy that the reactants must have in order to form the transition state and transform to product molecules. $E_{a}$ can be calculated from the total energy of the transition state relative to that of the reactants and is achieved when the thermal energy of the reactants overcomes the energy deficit between the energy of the reactants and that of the transition state. The preexponential factor corresponds to the collision frequency and energy of collisions upon which the formation of the transition state is dependent.

For bimolecular reactions, transition state theory yields [124]:

$$
\begin{equation*}
k(T)=\frac{1}{\left(k_{B} T\right) h} \gamma(T) K^{\circ} \exp \left(-\Delta G_{T}^{\ddagger \circ} / R T\right) \tag{16.180}
\end{equation*}
$$

where $\Delta G_{T}^{\ddagger \circ}$ is the quasi-thermodynamic free energy of activation, $\gamma(T)$ is a transmission coefficient, $K^{\circ}$ is the reciprocal of the concentration, $h$ is Planck's constant, and $k_{B}$ is the Boltzmann constant. The factor $\frac{1}{\left(k_{B} T\right) h}$ is obtained by dynamical classical equations of motion involving species trajectories having a statistical mechanical distribution. Specifically, the reactant molecular distribution is typically a Maxwell-Boltzmann distribution. The classical derivation of the preexponential term of the Arrhenius equation can be found in textbooks and review articles such as section 2.4 of Ref. [124]. Typically the $A$ term can be accurately determined from the Maxwell-Boltzmann-distribution-constrained classical equations of motion by sampling or by
using Monte Carlo methods on many sets (usually more than ten thousand) of initial conditions for the coordinates and momenta involving the trajectories. The translational levels are a continuous distribution, and the rotational and vibrational levels are quantized according to the classical equations given, for example, in the Vibration of the Hydrogen Molecular Ion section and the Diatomic Molecular Rotation section.

## SN2 REACTION OF $\mathrm{Cl}^{-}$WITH $\mathrm{CH}_{3} \mathrm{Cl}$

Consider the $\mathrm{S}_{\mathrm{N}} 2$ (bimolecular nucleophilic substitution) gas-phase reaction of $\mathrm{Cl}^{-}$with chloromethane through a transition state:

$$
\begin{equation*}
\mathrm{Cl}^{-}+\mathrm{CH}_{3} \mathrm{Cl} \rightarrow \mathrm{ClCH}_{3}+\mathrm{Cl}^{-} \tag{16.181}
\end{equation*}
$$

The corresponding Arrhenius equation for the reaction given by Eq. (16.179) is:

$$
\begin{equation*}
k(T)=\frac{k_{B} T}{h} \frac{Q^{\ddagger}}{\Phi^{R}} e^{\frac{-\Delta E^{\ddagger}}{k_{B} T}} \tag{16.182}
\end{equation*}
$$

where $k_{B}$ is the Boltzmann constant, $h$ is Planck's constant, $\Delta E^{\ddagger}$ is the activation energy of the transition state $\ddagger, T$ is the temperature, $\Phi^{R}$ is the reaction partition per unit volume, and $Q^{\ddagger}$ is the coordinate independent transition-state partition function. The preexponential factor $\frac{k_{B} T}{h} \frac{Q^{\ddagger}}{\Phi^{R}}$ has previously been calculated classically and shown to be in agreement with the experimental rate constant [125]. Then, only the transition state need be calculated and its geometry and energy compared to observations to confirm that classical physics is predictive of reaction kinetics. The activation energy can be calculated by determining the energy at the point that the nascent bond with the chloride ion is the same as that of the leaving chlorine wherein the negative charge is equally distributed on the chlorines. The rearrangement of bonds and the corresponding electron MOs of the reactants and products can be modeled as a continuous transition of the bond orders of the participating bonds from unity to zero and vice versa, respectively, wherein the transition state is a minimum-energy molecule having bonds between all of the reactants, $\mathrm{Cl}^{-}$and $\mathrm{CH}_{3} \mathrm{Cl}$.

## TRANSITION STATE

The reaction proceeds by back-side attack of $\mathrm{Cl}^{-}$on $\mathrm{CH}_{3} \mathrm{Cl}$. Based on symmetry, the reaction pathway passes through a $D_{3 h}$ configuration having $\mathrm{Cl}^{\delta^{-}}-\mathrm{C}-\mathrm{Cl}^{\delta^{-}}$on the $C_{3}$ axis. The hydrogen atoms are in the $\sigma_{h}$ plane with the bond distances the same as those of the $\mathrm{CH}_{3}$ functional group given in the Alkyl Chlorides section, since this group is not involved in the substitution reaction. The transition-state group $\mathrm{Cl}^{\delta^{-}}-\mathrm{C}-\mathrm{Cl}^{\delta^{-}}$is treated as a three-centered-bond functional group that comprises a linear combination of $\mathrm{Cl}^{-}$and the $\mathrm{C}-\mathrm{Cl}$ group of chloromethane ( $\mathrm{C}-\mathrm{Cl}$ (i) given in Table 15.33). It is solved using the Eq. (15.51) with the total energy matched to the sum of the $H_{2}$-type ellipsoidal MO total energy, -31.63536831 eV given by Eq. (11.212) as in the case of chloromethane, and the energy of the two outer electrons of $\mathrm{Cl}^{-}$, $E\left(C l^{-}\right)=-I P_{1}-I P_{2}=-12.96764 \mathrm{eV}-3.612724 \mathrm{eV}=-16.58036 \mathrm{eV} \quad[15,126]$. These electrons are contributed to form the back-side-attack bond. Then, the corresponding parameter $E_{T}\left({ }_{\text {AO/HO }}\right)(\mathrm{eV})$ is $-14.63489 \mathrm{eV}-16.58036 \mathrm{eV}=-31.21525 \mathrm{eV}$ due to the match of the MO energy to both $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)) and $E\left(C l^{-}\right)$, and $E_{\text {initial }}\left(c_{5} A O / H O\right)(e V)$ is -16.58036 eV corresponding to the initial energy of the $\mathrm{Cl}^{-}$electrons. Also, due to the two $\mathrm{C}-\mathrm{Cl}$ bonds of the $\mathrm{Cl}^{\delta^{-}}-\mathrm{C}-\mathrm{Cl}^{\delta^{-}}$functional group $n_{1}=2$. Otherwise all of the parameters of Eq. (15.51) remain the same as those of chloromethane given in Table 15.36. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters are given in Tables 16.42, 16.43, and 16.44, respectively. The color scale, translucent view of the charge density of the chloride-ion-chloromethane transition state comprising the $\mathrm{Cl}^{\delta^{-}}-\mathrm{C}-\mathrm{Cl}^{\delta^{-}}$ functional group is shown in Figure 16.17. The transition state bonding comprises two paired electrons in each $\mathrm{Cl}^{\delta^{-}}-\mathrm{C}$ MO with two from $\mathrm{Cl}^{-}$, one from Cl and one from $\mathrm{CH}_{3}$. As a symmetrical three-centered bond, the central bonding species are two Cl bound to a central $\mathrm{CH}_{3}^{+}$per $\mathrm{Cl}^{\delta^{-}}-\mathrm{C}$ MO with a continuous current onto the $\mathrm{C}-\mathrm{H} \mathrm{MO}$ at the intersection of each $\mathrm{Cl}^{\delta^{-}}-\mathrm{C}$ MO with the $\mathrm{CH}_{3}^{+}$group. Due to the four electrons and the valence of the chlorines, the latter possess a partial negative charge of $-0.5 e$ distributed on each $\mathrm{Cl}^{\delta^{-}}-C \mathrm{MO}$ such that the far field is equivalent to that of the corresponding point charge at each $C l$ nucleus.

Figure 16.17. Color scale, translucent view of the chloride-ion-chloromethane transition state comprising the $\mathrm{Cl}^{\delta^{-}}-\mathrm{C}-\mathrm{Cl}^{\delta^{-}}$functional group showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

The bond energy of the $\mathrm{C}-\mathrm{Cl}$ group of chloromethane from Table 15.36 is $E_{D}($ Group $)(\mathrm{eV})=3.77116 \mathrm{eV}$ compared to the bond energy of the $C l^{\delta^{-}}-C-C l^{\delta^{-}}$functional group of the chloride-ion-chloromethane transition state of $E_{D}($ Group $)(\mathrm{eV})=3.73930 \mathrm{eV}$ (Table 16.44). Since the energies of the $\mathrm{CH}_{3}$ functional groups are unchanged, the chloride-ionchloromethane transition state is $\Delta E=+0.03186 \mathrm{eV}(+0.73473 \mathrm{kcal} /$ mole $)$ higher in energy than chloromethane. Experimentally, the transition state is about $1 \pm 1 \mathrm{kcal} /$ mole higher [128]. Using this energy as the corresponding activation energy $\Delta E^{\ddagger}$ of Eq. (16.182) with the classically determined preexponential factor $\frac{k_{B} T}{h} \frac{Q^{\ddagger}}{\Phi^{R}}$ predicts the experimental reaction rate very well [125] :.

## NEGATIVELY-CHARGED MOLECULAR ION COMPLEX $\mathbb{C}$

In addition to the nature and energy of the transition state designated by $\ddagger$, experimental gas-phase rate constants indicate that the reaction of $\mathrm{Cl}^{-}$with $\mathrm{CH}_{3} \mathrm{Cl}$ passes through a bound state comprising the attachment of $\mathrm{Cl}^{-}$to the positive dipole of $\mathrm{CH}_{3} \mathrm{Cl}$ $[125,127,128]$ (the dipole moment of the $\mathrm{C}-\mathrm{Cl}$ functional group is given in the Bond and Dipole Moments section). This negatively-charged molecular ion complex designated $\mathbb{C}$ exists as a more stable state in between the reactants and the transition state, and by equivalence of the chlorines, it also exists between the transition state and the products. Experimentally $\mathbb{C}$ is $12.2 \pm 2 \mathrm{kcal} /$ mole more stable than the isolated reactants and products, $\mathrm{Cl}^{-}$and $\mathrm{CH}_{3} \mathrm{Cl}$. Thus, an energy well corresponding to $\mathbb{C}$ occurs on either side of the energy barrier of the transition state $\ddagger$ that is about $1 \pm 1 \mathrm{kcal} /$ mole above the reactants and products $[125,128]$. Thus, the combination of the depth of this well and the barrier height yields an intrinsic barrier to nucleophilic substitution given by the reaction of Eq. (16.181) of $13.2 \pm 2.2 \mathrm{kcal} / \mathrm{mole}$ [125, 128].

The negatively-charged molecular ion complex $\mathbb{C}$ comprises the functional groups of $\mathrm{CH}_{3} \mathrm{Cl}\left(\mathrm{C}-\mathrm{Cl}\right.$ (i) and $\mathrm{CH}_{3}$ given
in Table 15.33 of the Alkyl Chlorides section) and a $\mathrm{Cl}^{-} \cdot \mathrm{C}^{\delta^{+}}$functional group wherein $\mathrm{Cl}^{-}$is bound to the $\mathrm{CH}_{3} \mathrm{Cl}$ moiety by an ion-dipole bond. As given in the case of the dipole-dipole bonding of ice, liquid water, and water vapor as well as the van der Waals bonding in graphite and noble gases given in the Condensed Matter Physics section, the bond energy and bond distance of the $\mathrm{Cl}^{-} \cdot \mathrm{C}^{\delta^{+}}$functional group are determined by the limiting energy and distance of the formation of a corresponding nascent $\mathrm{Cl}^{-}-\mathrm{CH}_{3} \mathrm{Cl}$ covalent bond that destabilizes the $\mathrm{C}-\mathrm{Cl}$ bond of the $\mathrm{CH}_{3} \mathrm{Cl}$ moiety by involving charge density of its electrons in the formation the nascent bond. Subsequently, the higher energy $\mathrm{Cl}^{\delta^{-}}-\mathrm{C}-\mathrm{Cl}^{\delta^{-}}$functional group of the transition state is formed.

The energy and geometric parameters of the $\mathrm{Cl}^{-} \cdot \mathrm{C}^{\delta^{+}}$functional group are solved using Eq. (15.51) with the total energy matched to the $H_{2}$-type ellipsoidal MO total energy, -31.63536831 eV . The parameter $E_{T}(А о / н о)(\mathrm{eV})$ is $-14.63489 \mathrm{eV}-3.612724 \mathrm{eV}=-18.24761 \mathrm{eV}$ due to the match of the MO energy to both $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)) and the outer electron of $E\left(C l^{-}\right)\left(-I P_{1}=-3.612724 \mathrm{eV}\right)$ [126] that forms the nascent bond by the involving the electrons of the $\mathrm{C}-\mathrm{Cl}$ group of the $\mathrm{CH}_{3} \mathrm{Cl}$ moiety. Then, $E_{\text {initial }}\left(c_{\mathrm{c}} А О / Н о\right)(\mathrm{eV})$ is -3.612724 eV corresponding to the initial energy of the outer $\mathrm{Cl}^{-}$electron. Also, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ in Eq. $(15.61)$ is -1.85836 eV due to the charge donation from the $C \mathrm{HO}$ to the MO based on the energy match between the $C 2 s p^{3}$ HOs corresponding to the energy contribution of methylene, -0.92918 eV (Eq. (14.513)). $\quad E_{m a g}=0$ since the $\mathrm{Cl}^{-}$electrons are paired upon dissociation, and the vibrational energy of the transition state is appropriate for $\mathrm{Cl}^{-} \cdot C^{\delta^{+}}$. Otherwise, all of the parameters of Eq. (15.51) remain the same as those of chloromethane given in Table 15.36. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters are given in Tables 16.45, 16.46, and 16.47, respectively. The color scale, translucent view of the charge density of the negatively-charged molecular ion complex $\mathbb{C}$ comprising the $\mathrm{Cl}^{-} \cdot \mathrm{C}^{\delta^{+}}$ functional group is shown in Figure 16.18. The bonding in the $\mathbb{C}$ complex comprises two paired electrons in the $\mathrm{Cl}^{-} \cdot \mathrm{C}^{\delta^{+}}$MO with $1 / 2$ of the charge density from $\mathrm{Cl}^{-}$and the other half from $\mathrm{CH}_{3}$. The central bonding species are a Cl bound to a central $\mathrm{CH}_{3}^{+}$with a continuous current onto the $\mathrm{C}-\mathrm{H} \mathrm{MO}$ at the intersection of the $\mathrm{Cl}^{-} \cdot \mathrm{C}^{\delta^{+}} \mathrm{MO}$ with the $\mathrm{CH}_{3}^{+}$group. Due to the two electrons and the valence of the chlorine, the latter possess a negative charge of $-e$ distributed on the $C l^{-} \cdot C^{\delta^{+}}$MO such that the far field is equivalent to that of the corresponding point charge at the Cl nucleus. The bonding in the $\mathrm{CH}_{3} \mathrm{Cl}$ moiety is equivalent to that of chloromethane except that the $\mathrm{C}-\mathrm{H}$ bonds are in a plane to accommodate the $\mathrm{Cl}^{-} \cdot \mathrm{C}^{\delta^{+}} \mathrm{MO}$.

The bond energies of the $\mathrm{CH}_{3} \mathrm{Cl}$ moiety are unchanged to the limit of the formation of the $\mathrm{Cl}^{-} \cdot \mathrm{C}^{\delta^{+}}$functional group of the negatively-charged molecular ion complex $\mathbb{C}$. Thus, the energy of stabilization of forming the ion-dipole complex is equivalent to the bond energy of the $\mathrm{Cl}^{-} \cdot \mathrm{C}^{\delta^{+}}$functional group. Experimentally $\mathbb{C}$ is $12.2 \pm 2 \mathrm{kcal} / \mathrm{mole}$ more stable than the isolated reactants and products $[125,127,128], \mathrm{Cl}^{-}$and $\mathrm{CH}_{3} \mathrm{Cl}$. The bond energy of the $\mathrm{Cl}^{-} \cdot \mathrm{C}^{\delta^{+}}$functional group of the negatively-charged molecular ion complex $\mathbb{C}$ of $E_{D}($ Group $)=12.08900 \mathrm{kcal} /$ mole $(0.52422 \mathrm{eV})$ given in Table 16.47 matches the experimental stabilization energy very well. A simulation of the reaction of Eq. (16.181) is available on the internet [130].

## Chapter 17

## NATURE OF THE SOLID MOLECULAR BOND OF THE THREE ALLOTROPES OF CARBON

## GENERAL CONSIDERATIONS OF THE SOLID MOLECULAR BOND

The solid molecular bond of a material comprising an arbitrary number of atoms can be solved using similar principles and procedures as those used to solve organic molecules of arbitrary length. Molecular solids are also comprised of functional groups. Depending on the material, exemplary groups are $C-C, C=C, C-O, C-N, C-S$, and others given in the Organic Molecular Functional Groups and Molecules section. The solutions of these functional groups or any others corresponding to the particular solid can be conveniently obtained by using generalized forms of the geometrical and energy equations given in the Derivation of the General Geometrical and Energy Equations of Organic Chemistry section. The appropriate functional groups with their geometrical parameters and energies can be added as a linear sum to give the solution of any molecular solid.

## DIAMOND

It is demonstrated in this Diamond section as well as the Fullerene ( $C_{60}$ ) and Graphite sections, that very complex macromolecules can be simply solved from the groups at each vertex carbon atom of the structure. Specifically, for fullerene a $C=C$ group is bound to two $C-C$ bonds at each vertex carbon atom of $C_{60}$. The solution of the macromolecule is given by superposition of the geometrical and energy parameters of the corresponding two groups. In graphite, each sheet of joined hexagons can be constructed with a $C=C$ group bound to two $C-C$ bonds at each vertex carbon atom that hybridize to an aromatic-like functional group, $C \stackrel{8 / 3 e}{=} C$, with $\frac{8}{3}$ electron-number per bond compared to the pure aromatic functional group,
$C \stackrel{3 e}{=} C$, with 3 electron-number per bond as given the Aromatics section. Similarly, diamond comprising, in principle, an infinite network of carbons can be solved using the functional group solutions where the task is also simple since diamond has only one functional group, the diamond $C-C$ functional group.

The diamond $C-C$ bonds are all equivalent, and each $C-C$ bond can be considered bound to a t-butyl group at the corresponding vertex carbon. Thus, the parameters of the diamond $C-C$ functional group are equivalent to those of the t-butyl $C-C$ group of branched alkanes given in the Branched Alkanes section. Based on symmetry, the parameter $R$ in Eqs. (15.56) and (15.61) is the semimajor axis $a$, and the vibrational energy in the $\bar{E}_{\text {osc }}$ term is that of diamond. Also, the $C 2 s p^{3} \mathrm{HO}$ magnetic energy $E_{\text {mag }}$ given by Eq. (15.67) was subtracted for each t-butyl group of alkyl fluorides, alkyl chlorides, alkyl iodides, thiols, sulfides, disulfides, and nitroalkanes as given in the corresponding sections of Chapter 15 due to a set of unpaired electrons being created by bond breakage. Since each $C-C$ group of diamond bonds with a t-butyl group at each vertex carbon, $c_{3}$ of Eq. (15.65) is one, and $E_{\text {mag }}$ is given by Eq. (15.67).

The symbol of the functional group of diamond is given in Table 17.1. The geometrical (Eqs. (15.1-15.5) and (15.51)) parameters of diamond are given in Table 17.2. The lattice parameter $a_{l}$ was calculated from the bond distance using the law of cosines:

$$
\begin{equation*}
s_{1}{ }^{2}+s_{2}{ }^{2}-2 s_{1} s_{2} \operatorname{cosine} \theta=s_{3}{ }^{2} \tag{17.1}
\end{equation*}
$$

With the bond angle $\theta_{\angle C C C}=109.5^{\circ}$ [1] and $s_{1}=s_{2}=2 c_{C-C}^{\prime}$, the internuclear distance of the $C-C$ bond, $s_{3}=2 c_{C_{t}-C_{t}}^{\prime}$, the internuclear distance of the two terminal $C$ atoms is given by:

$$
\begin{equation*}
2 c_{C_{t}-C_{t}}^{\prime}=\sqrt{2\left(2 c_{C-C}^{\prime}\right)^{2}\left(1-\operatorname{cosine}\left(109.5^{\circ}\right)\right)} \tag{17.2}
\end{equation*}
$$

Two times the distance $2 c_{C_{t}-C_{t}}^{\prime}$ is the hypotenuse of the isosceles triangle having equivalent sides of length equal to the lattice parameter $a_{l}$. Using Eq. (17.2) and $2 c_{C-C}^{\prime}=1.53635 \AA$ from Table 17.2, the lattice parameter $a_{l}$ for the cubic diamond structure is given by:

$$
\begin{equation*}
a_{l}=\frac{2\left(2{c_{c_{t}-C_{t}}^{\prime}}_{\prime}\right)}{\sqrt{2}}=\sqrt{2} \sqrt{2\left(2{c^{\prime}}_{C-C}^{\prime}\right)^{2}\left(1-\operatorname{cosine}\left(109.5^{\circ}\right)\right)}=3.54867 \AA \tag{17.3}
\end{equation*}
$$

The intercept (Eqs. (15.80-15.87)) and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of diamond are given in Tables 17.2, 17.3, and 17.4, respectively. The total energy of diamond given in Table 17.5 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 17.4 corresponding to functional-group composition of the molecular solid. The experimental $C-C$ bond energy of diamond, $E_{D_{\text {cxp }}}(C-C)$ at 298 K , is given by the difference between the enthalpy of formation of gaseous carbon atoms from graphite $\left(\Delta H_{f}\left(C_{\text {graphite }}(g a s)\right)\right.$ ) and the heat of formation of diamond $\left(\Delta H_{f}(C(\right.$ diamond $\left.))\right)$ wherein graphite has a defined heat of formation of zero $\left(\Delta H_{f}(C(\right.$ graphite $)=0)$ :

$$
\begin{equation*}
E_{D_{\text {exp }}}(C-C)=\frac{1}{2}\left[\Delta H_{f}\left(C_{\text {grappite }}(\text { gas })\right)-\Delta H_{f}(C(\text { diamond }))\right] \tag{17.4}
\end{equation*}
$$

where the heats of formation of atomic carbon and diamond are [2]:

$$
\begin{align*}
& \Delta H_{f}\left(C_{\text {graphite }}(\text { gas })\right)=716.68 \mathrm{~kJ} / \text { mole }(7.42774 \mathrm{eV} / \text { atom })  \tag{17.5}\\
& \Delta H_{f}(C(\text { diamond }))=1.9 \mathrm{~kJ} / \text { mole }(0.01969 \mathrm{eV} / \text { atom }) \tag{17.6}
\end{align*}
$$

Using Eqs. (17.4-17.6), $E_{D_{\text {exp }}}(C-C)$ is:

$$
\begin{equation*}
E_{D_{\text {exp }}}(C-C)=\frac{1}{2}[7.42774 \mathrm{eV}-0.01969 \mathrm{eV}]=3.704 \mathrm{eV} \tag{17.7}
\end{equation*}
$$

where the factor of one half corresponds to the ratio of two electrons per bond and four electrons per carbon atom. The bond angle parameters of diamond determined using Eqs. $(15.88-15.117)$ are given in Table 17.6. The structure of diamond is shown in Figure 17.1.

## FULLERENE ( $C_{60}$ )

$C_{60}$ comprises 60 equivalent carbon atoms that are bound as 60 single bonds and 30 double bonds in the geometric form of a truncated icosahedron: twelve pentagons and twenty hexagons joined such that no two pentagons share an edge. To achieve this minimum energy structure each equivalent carbon atom serves as a vertex incident with one double and two single bonds. Each type of bond serves as a functional group which has aromatic character. The aromatic bond is uniquely stable and requires the sharing of the electrons of multiple $\mathrm{H}_{2}$-type MOs. The results of the derivation of the parameters of the benzene molecule given in the Benzene Molecule $\left(C_{6} H_{6}\right)$ section was generalized to any aromatic functional group of aromatic and heterocyclic compounds in the Aromatic and Heterocyclic Compounds section. Ethylene serves as a basis element for the $C={ }_{=}^{3 e} C$ bonding of the aromatic bond wherein each of the $C \stackrel{3 e}{=} C$ aromatic bonds comprises $(0.75)(4)=3$ electrons according to Eq. (15.161) wherein $C_{2}$ of Eq. (15.51) for the aromatic $C=C$-bond MO given by Eq. (15.162) is $C_{2}\left(\right.$ aromatic $\left.C 2 s p^{3} \mathrm{HO}\right)=c_{2}\left(\right.$ aromatic $\left.C 2 s p^{3} \mathrm{HO}\right)=0.85252$ and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} \cdot \mathrm{AO}\right)=-2.26759 \mathrm{eV}$. In $C_{60}$, the minimum energy structure with equivalent carbon atoms wherein each carbon forms bonds with three other such carbons requires a redistribution of charge within an aromatic system of bonds. The $C=C$ functional group of $C_{60}$ comprises the aromatic bond with the exception that it comprises four electrons. Thus, $E_{T}(G r o u p)$ and $E_{D}($ Group $)$ are given by Eqs. (15.165) and (15.166), respectively, with $f_{1}=1, c_{4}=4$, and $\bar{E}_{\text {Kvib }}(\mathrm{eV})$ is that of $C_{60}$.

In addition to the $C=C$ bond, each vertex carbon atom of $C_{60}$ is bound to two $C-C$ bonds that substitute for the aromatic $C \stackrel{3 e}{=} C$ and $C-H$ bonds. As in the case of the $C-C$-bond MO of naphthalene, to match energies within the MO that bridges single and double-bond MOs, $E(\mathrm{AO} / \mathrm{HO})$ and $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}(\mathrm{AO} / \mathrm{HO})$ in Eq. $(15.51)$ are -14.63489 eV and -2.26759 eV , respectively.

To meet the equipotential condition of the union of the $C 2 s p^{3} \mathrm{HOs}$ of the $C-C$ single bond bridging double bonds, the parameters $c_{1}, C_{2}$, and $C_{2 o}$ of Eq. (15.51) are one for the $C-C$ group, $C_{1 o}$ and $C_{1}$ are 0.5 , and $c_{2}$ given by Eq. (13.430) is $c_{2}\left(C 2 s p^{3} H O\right)=0.91771$. To match the energies of the functional groups with the electron-density shift to the double bond, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of each of the equivalent $C-C$-bond MOs in Eq. (15.61) due to the charge donation from the $C$ atoms to the MO can be considered a linear combination of that of $C-C$-bond MO of toluene, -1.13379 eV and the that of the aromatic $C-H$-bond MO, $\frac{-1.13379 \mathrm{eV}}{2}$. Thus, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of each $C-C$-bond MO of $C_{60}$ is $\frac{-1.13379 \mathrm{eV}+0.5(-1.13379 \mathrm{eV})}{2}=0.75(-1.13379 \mathrm{eV})=-0.85034 \mathrm{eV}$. As in the case of the aromatic $C-H$ bond, $c_{3}=1 \mathrm{in}$ Eq. (15.65) with $E_{\text {mag }}$ given by Eq. (15.67), and $\bar{E}_{K v i b}(\mathrm{eV})$ is that of $C_{60}$.

The symbols of the functional groups of $C_{60}$ are given in Table 17.7. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of $C_{60}$ are given in Tables $17.8,17.9$, and 17.10 , respectively. The total energy of $C_{60}$ given in Table 17.11 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 17.10 corresponding to functional-group composition of the molecule. The bond angle parameters of $C_{60}$ determined using Eqs. (15.87-15.117) are given in Table 17.12. The structure of $C_{60}$ is shown in Figures 17.2 A and B . The fullerene vertex-atom group comprising a double and two single bonds can serve as a basis element to form other higher-order fullerene-type macromolecules, hyperfullerenes, and complex hybrid conjugated carbon and aromatic structures comprising a mixture of elements from the group of fullerene, graphitic, and diamond carbon described in the corresponding sections.

Figure 17.2. $C_{60}$ MO comprising a hollow cage of sixty carbon atoms bound with the linear combination of sixty sets of $C-C$-bond MOs bridged by 30 sets of $C=C$-bond MOs. A $C=C$ group is bound to two $C-C$ groups at each vertex carbon atom of $C_{60}$. Color scale, translucent pentagonal view (A), and hexagonal view (B), of the charge-density of the $C_{60}$-bond MO with each $C 2 s p^{3}$ HO shown transparently. For each $C-C$ and $C=C$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C 2 s p^{3} \mathrm{HO}$, the $C 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown.

## FULLERENE DIHEDRAL ANGLES

For $C_{60}$, the bonding at each vertex atom $C_{b}$ comprises two single bonds, $C_{a}-C_{b}-C_{a}$, and a double bond, $C_{b}=C_{c}$. The dihedral angle $\theta_{\angle C=C / C-C-C}$ between the plane defined by the $C_{a}-C_{b}-C_{a}$ moiety and the line defined by the corresponding $C_{b}=C_{c}$ moiety is calculated using the results given in Table 17.12 and Eqs. (15.114-15.117). The distance $d_{1}$ along the bisector of $\theta_{\angle C_{a}-C_{b}-C a}$ from $C_{b}$ to the internuclear-distance line between one $C_{a}$ and the other $C_{a}, 2 c^{\prime}{ }_{C_{a}-C_{a}}$, is given by:

$$
\begin{equation*}
d_{1}=2{c^{\prime}}_{C_{b}-C_{a}}^{\prime} \cos \frac{\theta_{\angle C_{a}-C_{b}-C a}}{2}=2.74663 a_{0} \cos \frac{108.00^{\circ}}{2}=1.61443 a_{0} \tag{17.8}
\end{equation*}
$$

where $2{c^{\prime}}_{C_{b}-C_{a}}$ is the internuclear distance between $C_{b}$ and $C_{a}$. The atoms $C_{a}, C_{a}$, and $C_{c}$ define the base of a pyramid. Then, the pyramidal angle $\theta_{\left\langle C_{a} C_{c} C_{a}\right.}$ can be solved from the internuclear distances between $C_{c}$ and $C_{a}, 2 c^{\prime}{ }_{C_{c}-C_{a}}$, and between $C_{a}$ and $C_{a}, 2{c^{\prime}}_{C_{a}-C_{a}}$, using the law of cosines (Eq. (15.115)).

$$
\begin{equation*}
=57.01^{\circ} \tag{17.9}
\end{equation*}
$$

Then, the distance $d_{2}$ along the bisector of $\theta_{\angle C_{a} C_{c} C_{a}}$ from $C_{c}$ to the internuclear-distance line $2 c^{\prime}{ }_{C_{a}-C_{a}}$, is given by:

$$
\begin{equation*}
d_{2}=2 c_{C_{c}-C_{a}}^{\prime} \cos \frac{\theta_{\angle C_{a} C_{c} C_{a}}}{2}=4.65618 a_{0} \cos \frac{57.01^{\circ}}{2}=4.09176 a_{0} \tag{17.10}
\end{equation*}
$$

The lengths $d_{1}, d_{2}$, and $2 c_{C_{b}=C_{c}}^{\prime}$ define a triangle wherein the angle between $d_{1}$ and the internuclear distance between $C_{b}$ and $C_{c}, 2 c^{\prime}{ }_{C_{b}=C_{c}}$, is the dihedral angle $\theta_{\angle C=C / C-C-C}$ that can be solved using the law of cosines (Eq. (15.117)).

$$
\begin{align*}
\theta_{\angle C=C / C-C-C} & =\cos ^{-1}\left(\frac{d_{1}^{2}+\left(2{c^{\prime}}_{C_{b}=C_{c}}\right)^{2}-d_{2}^{2}}{2 d_{1}\left(2{c^{\prime}}_{C_{b}=C_{c}}\right)}\right)=\cos ^{-1}\left(\frac{\left(1.61443 \mathrm{a}_{0}\right)^{2}+\left(2.62936 \mathrm{a}_{0}\right)^{2}-\left(4.09176 \mathrm{a}_{0}\right)^{2}}{2\left(1.61443 \mathrm{a}_{0}\right)\left(2.62936 \mathrm{a}_{0}\right)}\right)  \tag{17.11}\\
& =148.29^{\circ}
\end{align*}
$$

The dihedral angle for a truncated icosahedron corresponding to $\theta_{\angle C=C / C-C-C}$ is:

$$
\begin{equation*}
\theta_{\angle C=C / C-C-C}=148.28^{\circ} \tag{17.12}
\end{equation*}
$$

The dihedral angle $\theta_{\angle C-C / C-C=C}$ between the plane defined by the $C_{a}-C_{b}=C_{c}$ moiety and the line defined by the corresponding $C_{b}-C_{a}$ moiety is calculated using the results given in Table 17.12 and Eqs. (15.118-15.127). The parameter $d_{1}$ is the distance from $C_{b}$ to the internuclear-distance line between $C_{a}$ and $C_{c}, 2 c^{\prime}{ }_{C_{a}-C_{c}}$. The angle between $d_{1}$ and the $C_{b}-C_{a}$ bond, $\theta_{\angle C_{a} C_{b} d_{1}}$, can be solved reiteratively using Eq. (15.121).

$$
\begin{align*}
& \binom{\left.\left(2 c^{\prime}{ }_{C_{b}-C_{a}}\right)^{2}+\left(\frac{\left(2{\left.c^{\prime}{ }_{C_{b}-C_{a}}\right)^{2}-\left(2 c^{\prime}{ }_{C_{b}-C_{c}}\right.}\right)^{2}}{2\left(\left(2 c^{\prime}{ }_{C_{b}-C_{a}}\right) \operatorname{cosine} \theta_{\angle C_{a} C_{b} d_{1}}-\left(2 c^{\prime}{ }_{C_{b}-C_{c}}\right) \operatorname{cosine}\left(\theta_{\angle C_{a} C_{b} C_{c}}-\theta_{\angle C_{a} C_{b} d_{1}}\right)\right)}\right)^{2}\right) \operatorname{cosine} \theta_{\angle C_{a} C_{b} d_{1}}}{-2\left(2{\left.c^{\prime}{ }_{C_{b}-C_{a}}\right)}\right)\binom{2\left(2 c^{\prime}{ }^{\prime}{ }_{C_{b}-C_{a}}\right) \operatorname{cosine} \theta_{\angle C_{a} C_{b} d_{1}}}{-\left(2 c^{\prime}{ }_{C_{b}-C_{c}}\right) \operatorname{cosine}\left(\theta_{\angle C_{a} C_{b} C_{c}}-\theta_{\angle C_{a} C_{b} d_{1}}\right)}}=0 \\
& \left(\begin{array}{l}
\left.\left.\left(2.74663 \mathrm{a}_{0}\right)^{2}+\left(\frac{\left(2.74663 \mathrm{a}_{0}\right)^{2}-\left(2.62936 \mathrm{a}_{0}\right)^{2}}{2\left(\left(2.74663 \mathrm{a}_{0}\right) \operatorname{cosine} \theta_{\angle C_{a} C_{b} d_{1}}-\left(2.62936 \mathrm{a}_{0}\right) \operatorname{cosine}\left(120.00^{\circ}-\theta_{\angle C_{a} C_{b} d_{1}}\right)\right)}\right)^{2}\right) \operatorname{cosine} \theta_{\angle C_{a} C_{b} d_{1}}\right) \\
-\left(2\left(2.74663 \mathrm{a}_{0}\right)\left(\frac{\left(2.74663 \mathrm{a}_{0}\right)^{2}-\left(2.62936 \mathrm{a}_{0}\right)^{2}}{2\binom{\left(2.74663 \mathrm{a}_{0}\right) \operatorname{cosine} \theta_{\angle C_{a} C_{b} d_{1}}}{-\left(2.62936 \mathrm{a}_{0}\right) \operatorname{cosine}\left(120.00^{\circ}-\theta_{\angle C_{a} C_{b} d_{1}}\right)}}\right)\right. \\
-\left(\frac{4.6562 \mathrm{a}_{0}}{2}\right)^{2}
\end{array}\right)=0 \tag{17.13}
\end{align*}
$$

The solution of Eq. (17.13) is:

$$
\begin{equation*}
\theta_{\angle C_{a} C_{a} d_{2}}=57.810^{\circ} \tag{17.14}
\end{equation*}
$$

Eq. (17.14) can be substituted into Eq. (15.120) to give $d_{1}$ :

$$
\begin{align*}
d_{1} & =\frac{\left(2{c^{\prime}}_{C_{b}-C_{a}}\right)^{2}-\left(2{c^{\prime}}_{C_{b}-C_{c}}\right)^{2}}{2\left(\left(2{c^{\prime}{ }_{C_{b}-C_{a}}}\right) \operatorname{cosine} \theta_{\angle C_{a} C_{b} d_{1}}-\left(2{c^{\prime}}_{C_{b}-C_{c}}\right) \operatorname{cosine}\left(\theta_{\angle C_{a} C_{b} C_{c}}-\theta_{\angle C_{a} C_{b} d_{1}}\right)\right)}  \tag{17.15}\\
& =\frac{\left(2.74663 \mathrm{a}_{0}\right)^{2}-\left(2.62936 \mathrm{a}_{0}\right)^{2}}{2\left(\left(2.74663 \mathrm{a}_{0}\right) \operatorname{cosine}\left(57.810^{\circ}\right)-\left(2.62936 \mathrm{a}_{0}\right) \operatorname{cosine}\left(120.00^{\circ}-57.810^{\circ}\right)\right)}=1.33278 \mathrm{a}_{0}
\end{align*}
$$

The atoms $C_{a}, C_{a}$, and $C_{c}$ define the base of a pyramid. Then, the pyramidal angle $\theta_{\angle C_{a} C_{a} C_{c}}$ can be solved from the internuclear distances between $C_{a}$ and $C_{a}, 2 c^{\prime}{ }_{C_{a}-C_{a}}$, and between $C_{a}$ and $C_{c}, 2 c^{\prime}{ }_{C_{a}-C_{c}}$, using the law of cosines (Eq. (15.115)).

$$
\begin{align*}
& \theta_{\angle C_{a} C_{a} C_{c}}=\cos ^{-1}\left(\frac{\left(2 c_{C_{a}-C_{a}}\right)^{2}+\left(2{c^{\prime}}_{C_{a}-C_{c}}\right)^{2}-\left(2{\left.c^{\prime}{ }_{C_{a}-C_{c}}\right)^{2}}_{2\left(2 c^{\prime}{ }_{C_{a}-C_{a}}\right)\left(2 c^{\prime}{ }_{C_{a}-C_{c}}\right)}\right)}{}\right)  \tag{17.16}\\
& =\cos ^{-1}\left(\frac{\left(4.44410 \mathrm{a}_{0}\right)^{2}+\left(4.65618 \mathrm{a}_{0}\right)^{2}-\left(4.65618 \mathrm{a}_{0}\right)^{2}}{2\left(4.44410 \mathrm{a}_{0}\right)\left(4.65618 \mathrm{a}_{0}\right)}\right)=61.50^{\circ}
\end{align*}
$$

The parameter $d_{2}$ is the distance from $C_{a}$ to the bisector of the internuclear-distance line between $C_{a}$ and $C_{c}, 2 c^{\prime}{ }_{C_{a}-C_{c}}$. The angle between $d_{2}$ and the $C_{a}-C_{a}$ axis, $\theta_{\left\langle C_{a} C_{a} d_{2}\right.}$, can be solved reiteratively using Eq. (15.126).

$$
\begin{aligned}
& \left(\begin{array}{l}
\left.\left(4.44410 \mathrm{a}_{0}\right)^{2}+\left(\frac{\left(4.44410 \mathrm{a}_{0}\right)^{2}-\left(4.65618 \mathrm{a}_{0}\right)^{2}}{2\left(\left(4.44410 \mathrm{a}_{0}\right) \operatorname{cosine} \theta_{\angle C_{a} C_{a} d_{2}}-\left(4.65618 \mathrm{a}_{0}\right) \operatorname{cosine}\left(61.50^{\circ}-\theta_{\angle C_{a} C_{a} d_{2}}\right)\right)}\right)^{2}\right) \\
-\left(2\left(4.44410 \mathrm{a}_{0}\right)\left(\frac{\left(4.44410 \mathrm{a}_{0}\right)^{2}-\left(4.65618 \mathrm{a}_{0}\right)^{2}}{2\binom{\left(4.44410 \mathrm{a}_{0}\right) \operatorname{cosine} \theta_{\angle C_{a} C_{a} d_{2}}}{-\left(4.65618 \mathrm{a}_{0}\right) \operatorname{cosine}\left(61.50^{\circ}-\theta_{\angle C_{a} C_{a} d_{2}}\right)}}\right){\operatorname{cosine} \theta_{\angle C_{a} C_{a} d_{2}}}^{2}\right) \\
-\left(\frac{4.6562 \mathrm{a}_{0}}{2}\right)^{2}
\end{array}\right)=0
\end{aligned}
$$

The solution of Eq. (17.17) is:

$$
\begin{equation*}
\theta_{\angle C_{a} C_{a} d_{2}}=31.542^{\circ} \tag{17.18}
\end{equation*}
$$

Eq. (17.18) can be substituted into Eq. (15.125) to give $d_{2}$ :

$$
\begin{align*}
d_{2} & =\frac{\left(2{c^{\prime}}_{C_{a}-C_{a}}\right)^{2}-\left(2 c_{C_{a}-C_{c}}^{\prime}\right)^{2}}{2\left(\left(2{c^{\prime}{ }_{C_{a}-C_{a}}}\right) \operatorname{cosine} \theta_{\angle C_{a} C_{a} d_{2}}-\left(2{c^{\prime}{ }_{C_{a}-C_{c}}}\right) \operatorname{cosine}\left(\theta_{\angle C_{a} C_{a} C_{c}}-\theta_{\angle C_{a} C_{a} d_{2}}\right)\right)}  \tag{17.19}\\
& =\frac{\left(4.44410 \mathrm{a}_{0}\right)^{2}-\left(4.65618 \mathrm{a}_{0}\right)^{2}}{2\left(\left(4.44410 \mathrm{a}_{0}\right) \operatorname{cosine}\left(31.542^{\circ}\right)-\left(4.65618 \mathrm{a}_{0}\right) \operatorname{cosine}\left(61.50^{\circ}-31.542^{\circ}\right)\right)}=3.91101 \mathrm{a}_{0}
\end{align*}
$$

The lengths $d_{1}, d_{2}$, and $2 c^{\prime}{ }_{c_{b}-C_{a}}$ define a triangle wherein the angle between $d_{1}$ and the internuclear distance between $C_{b}$ and $C_{a}, 2 c^{\prime}{ }_{C_{b}-C_{a}}$, is the dihedral angle $\theta_{\angle C-C / C-C=C}$ that can be solved using the law of cosines (Eq. (15.117)).

$$
\begin{align*}
\theta_{\angle C-C / C-C=C} & =\cos ^{-1}\left(\frac{d_{1}^{2}+\left(2 c_{C_{b}-C_{a}}^{\prime}\right)^{2}-d_{2}^{2}}{2 d_{1}\left(2{c^{C_{b}-C_{a}}}^{\prime}\right)}\right)  \tag{17.20}\\
& =\cos ^{-1}\left(\frac{\left(1.33278 \mathrm{a}_{0}\right)^{2}+\left(2.74663 \mathrm{a}_{0}\right)^{2}-\left(3.91101 \mathrm{a}_{0}\right)^{2}}{2\left(1.33278 \mathrm{a}_{0}\right)\left(2.74663 \mathrm{a}_{0}\right)}\right)=144.71^{\circ}
\end{align*}
$$

The dihedral angle for a truncated icosahedron corresponding to $\theta_{\angle C-C / C-C=C}$ is:

$$
\begin{equation*}
\theta_{\angle C-C / C-C=C}=144.24^{\circ} \tag{17.21}
\end{equation*}
$$

## GRAPHENE AND GRAPHITE

In addition to fullerene and diamond described in the corresponding sections, graphite is the third allotrope of carbon. It comprises planar sheets of covalently bound carbon atoms arranged in hexagonal aromatic rings of a macromolecule of indefinite size. Each sheet comprises graphene. The sheets, in turn, are bound together by weaker intermolecular forces. It was demonstrated in the Fullerene $\left(C_{60}\right)$ section, that a very complex macromolecule, fullerene, could be simply solved from the groups at each vertex carbon atom of the structure. Specifically, a $C=C$ group is bound to two $C-C$ bonds at each vertex carbon atom of $C_{60}$. The solution of the macromolecule is given by superposition of the geometrical and energy parameters of the corresponding two groups. Similarly, diamond comprising, in principle, an infinite network of carbons was also solved in the Diamond section using the functional group solutions, the diamond $C-C$ functional group which is the only functional group of diamond.

The structure of the indefinite network of aromatic hexagons of a sheet of graphite can also be solved by considering the vertex atom. As in the case of fullerene, each sheet of joined hexagons can be constructed with a $C=C$ group bound to two $C-C$ bonds at each vertex carbon atom of graphite. However, an alternative bonding to that of $C_{60}$ is possible for graphite due to the structure comprising repeating hexagonal units. In this case, the lowest energy structure is achieved with a single functional group, one which has aromatic character. The aromatic bond is uniquely stable and requires the sharing of the electrons of multiple $\mathrm{H}_{2}$-type MOs. The results of the derivation of the parameters of the benzene molecule given in the Benzene Molecule ( $C_{6} H_{6}$ ) section was generalized to any aromatic functional group of aromatic and heterocyclic compounds in the Aromatic and Heterocyclic Compounds section. Ethylene serves as a basis element for the $C=C$ bonding of the aromatic bond wherein each of the $C \stackrel{3 e}{=} C$ aromatic bonds comprises $(0.75)(4)=3$ electrons according to Eq. (15.161) wherein $C_{2}$ of Eq. (15.51) for the aromatic $C \stackrel{3 e}{=} C$-bond MO given by Eq. (15.162) is $C_{2}\left(\right.$ aromatic $\left.C 2 s p^{3} H O\right)=c_{2}\left(\right.$ aromatic $\left.C 2 s p^{3} H O\right)=0.85252$ and $E_{T}\left(\right.$ atom-atom, msp $\left.^{3} . A O\right)=-2.26759 \mathrm{eV}$.

In graphite, the minimum energy structure with equivalent carbon atoms wherein each carbon forms bonds with three other such carbons requires a redistribution of charge within an aromatic system of bonds. Considering that each carbon contributes four bonding electrons, the sum of electrons of a vertex-atom group is four from the vertex atom plus two from each of the two atoms bonded to the vertex atom where the latter also contribute two each to the juxtaposed group. These eight electrons are distributed equivalently over the three bonds of the group such that the electron number assignable to each bond is $\frac{8}{3}$. Thus, the $C \stackrel{8 / 3 e}{=} C$ functional group of graphite comprises the aromatic bond with the exception that the electron-number per bond is $\frac{8}{3}$. $E_{T}($ Group $)$ and $E_{D}($ Group $)$ are given by Eqs. (15.165) and (15.166), respectively, with $f_{1}=\frac{2}{3}$ and $c_{4}=\frac{8}{3}$. As in the case of diamond comprising equivalent carbon atoms, the $C 2 s p^{3} \mathrm{HO}$ magnetic energy $E_{\text {mag }}$ given by Eq. (15.67) was subtracted due to a set of unpaired electrons being created by bond breakage such that $c_{3}$ of Eqs. (15.165) and (15.166) is one.

The symbol of the functional group of graphite is given in Table 17.13. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of graphite are given in Tables 17.14, 17.15, and 17.16, respectively. The total energy of graphite given in Table 17.17 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 17.16 corresponding to functional-group composition of the molecular solid. The experimental $C \stackrel{8 / 3 e}{=} C$ bond energy of graphite at $0 \mathrm{~K}, E_{D_{\text {exp }}}(C \stackrel{8 / 3 e}{=} C)$, is given by the difference between the enthalpy of formation of gaseous carbon atoms from graphite, $\Delta H_{f}\left(C_{\text {graphite }}(\right.$ gas $\left.)\right)$, and the interplanar binding energy, $E_{x}$, wherein graphite solid has a defined heat of formation of zero $\left(\Delta H_{f}(C(\right.$ graphite $)=0)$ :

$$
\begin{equation*}
E_{D_{\text {exp }}}(C \stackrel{8 / 3 e}{=} C)=\frac{2}{3}\left[\Delta H_{f}\left(C_{\text {graphite }}(\text { gas })\right)-E_{x}\right] \tag{17.22}
\end{equation*}
$$

The factor of $\frac{2}{3}$ corresponds to the ratio of $\frac{8}{3}$ electrons per bond and 4 electrons per carbon atom. The heats of formation of atomic carbon from graphite [9] and $E_{x}$ [10] are:

$$
\begin{align*}
& \Delta H_{f}\left(C_{\text {graphite }}(\text { gas })\right)=711.185 \mathrm{~kJ} / \text { mole }(7.37079 \mathrm{eV} / \text { atom })  \tag{17.23}\\
& E_{x}=0.0228 \mathrm{eV} / \text { atom } \tag{17.24}
\end{align*}
$$

Using Eqs. (17.21-17.23), $E_{D_{\text {exp }}}(C \stackrel{8 / 3 e}{=} C)$ is:

$$
\begin{equation*}
E_{D_{\text {cxp }}}(C \stackrel{8 / 3 e}{=} C)=\frac{2}{3}[7.37079 \mathrm{eV}-0.0228 \mathrm{eV}]=4.89866 \mathrm{eV} \tag{17.25}
\end{equation*}
$$

The bond angle parameters of graphite determined using Eqs. (15.87-15.117) are given in Table 17.18. The inter-plane distance for graphite of $3.5 \AA$ is calculated in the Geometrical Parameters Due to the Interplane van der Waals Cohesive Energy of Graphite section. The structure of graphite is shown in Figure 17.3A and B. The graphite $C \stackrel{8 / 3 e}{=} C$ functional group can serve as a basis element to form additional complex polycyclic aromatic carbon structures such as nanotubes [11-15].

## Chapter 18

# NATURE OF THE IONIC BOND OF ALKALI HYDRIDES AND HALIDES 

## ALKALI-HYDRIDE CRYSTAL STRUCTURES

The alkali hydrides are lithium hydride ( $L i H$ ), sodium hydride ( $N a H$ ), potassium hydride ( $K H$ ), rubidium hydride $(\mathrm{RbH}$ ), and cesium hydride ( CsH ). These saline or salt-like alkali-metal hydrides each comprise an equal number of alkali cations and hydride ions [1] in unit cells of a crystalline lattice. The crystal structure of these ionic compounds is the face-centered cubic NaCl structure [2]. This close-packed structure is expected since it gives the optimal approach of the positive and negative ions [3]. The structure comprises face-centered cubes of both $M^{+}$and $H^{-}$ions combined, but offset by half a unit cell length in one direction so that $M^{+}$ions are centered in the edges of the $H^{-}$lattice and vice versa. Each $M^{+}$is surrounded by six nearest neighbor $H^{-}$ions and vice versa. The resulting unit cell consists of anions (or cations) at the midpoint of each edge and at the center of the cell such that the unit cell contains four cations and four anions.

The interionic radius of each hydride can be derived by considering the radii of the alkali ion and the hydride ion, the electron energies at these radii, and the conditions for stability of the ions as the internuclear distance changes and the ions are mutually influenced by Coulombic forces. Then, the lattice energy is given by the sum over the crystal of the minimum energy of the interacting ion pairs at the radius of minimum approach for which the ions are stable. The sum is further over all Coulombic interactions of the ions of the crystal.

Each hydride $M H$ ( $M=L i, N a, K, R b, C s)$ is comprised of $M^{+}$and $H^{-}$ions. From Coulomb's Law, the lattice energy $\Delta U$ for point charges is given by the Born-Mayer equation [3]

$$
\begin{equation*}
\Delta U=N M_{c} Z_{+} Z_{-} \frac{e^{2}}{4 \pi \varepsilon_{0} r_{0}}\left(1-\frac{\rho}{r_{0}}\right) \tag{18.1}
\end{equation*}
$$

where $N$ is Avogadro's number, $M_{c}$ is the Madelung constant (the convergent sum of all Coulombic interactions of any given ion with the lattice of ions), $Z_{+}$and $Z_{-}$are the ionic charges in elementary charge units, $r_{0}$ is the distance between ion centers, and $\rho$ is a constant that corrects for higher-order terms (e.g. $1 / r_{0}^{6}$ to $1 / r_{0}^{12}$ terms) in repulsion between close neighbor ions. The $M-H$ distance can be calculated from the minimum energy packing of the ions, which is stable. Each ion is surrounded in a symmetrical octahedral field of six counterions. From Eq. (18.1), the lattice energy increases as the interionic distance decreases. But, the interionic distance cannot be the sum of the contact radii. This is easily appreciated by considering that the energies of the outer electron of $M^{+}$and the outer two electrons of $H^{-}$are very different. For sufficiently small interionic distances, the most energetic reaction that can occur which eliminates the cation and consequently the lattice energy is the following :

$$
\begin{equation*}
M^{+}+e^{-} \rightarrow M \tag{18.2}
\end{equation*}
$$

For shorter distances, the spherically symmetrical ${ }^{1} S_{0}$ state of the hydride ion is distorted by $M^{+}$, and it is not stable in the ionic crystal when the $M-H$ distance is given by the condition that the total Coulombic energy of attractive terms of $H^{-}$in the field of $M^{+}$as well as the repulsive terms between like-charged ions is equal to the binding energy of $M, B E(M)$, for the cations of the crystal. Then, the lattice energy is given by the product of Avogadro's number, $B E(M)$, and the Madelung constant which takes into account all inverse $r_{0}$ (point-like) Coulombic interactions of the crystal:

$$
\begin{equation*}
\Delta U=N M_{c} B E(M) \tag{18.3}
\end{equation*}
$$

Thus, $M_{c}$ is the factor of stability of forming the crystal from $M^{+}$and $H^{-}$ions. The value for the NaCl structure is $M_{c}=1.74756$ [3].

Since the Coulombic potential of the ions is equivalent to that of point charges with some higher order ion-ion-interaction repulsive terms, the $M-H$ distance $r_{0}(M H)$ given using Eq. (18.1), Eq. (18.3), and $B E(M)$ is:

$$
\begin{equation*}
r_{0}(M H)=\frac{\frac{Z_{+} Z_{-} e^{2}}{B E(M) 4 \pi \varepsilon_{0}}+\sqrt{\left(\frac{Z_{+} Z_{-} e^{2}}{B E(M) 4 \pi \varepsilon_{0}}\right)^{2}-\frac{4 \rho Z_{+} Z_{-} e^{2}}{B E(M) 4 \pi \varepsilon_{0}}}}{2} \tag{18.4}
\end{equation*}
$$

wherein $\rho=0.4 \times 10^{-10} \mathrm{~m}$ for alkali hydrides [4-5]. The parameters of the hydride ion are given in the corresponding section.

## LITHIUM HYDRIDE

The calculated ionic radii for $\mathrm{Li}^{+}$and $\mathrm{H}^{-}$ions given in Tables 7.1 and 7.2 are $0.35566 a_{0}$ and $1.8660 a_{0}$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of $\mathrm{Li}^{+}$(Eqs. (7.35), (7.45-7.46), and (7.63)) and $H^{-}$(Eq. (7.69)) are 75.665 eV and 0.75471 eV , respectively. Furthermore, since the calculated ionization energy (Eq. (10.25)) of Li to $\mathrm{Li}^{+}$is 5.40381 eV as shown in Table 10.1 and the ionization energy (Eq. (7.69)) of $H^{-}$to $H$ is $0.75471 \mathrm{eV}\left(1.20836 \times 10^{-19} \mathrm{~J}\right)$, for sufficiently small interionic distances, the lithium ion may be reduced.

Substitution of $B E(L i)=8.65786 \times 10^{-19} J$ into Eq. (18.3) gives the calculated lattice energy of
$\Delta U=N M_{c} B E(L i)=1.74756 N 8.65786 \times 10^{-19} \mathrm{~J}=911.1 \mathrm{~kJ} /$ mole $(217.8 \mathrm{kcal} / \mathrm{mole})$
This agrees well with the experimental lattice energy of $\Delta U=217.95 \mathrm{kcal} /$ mole [1] and confirms that the ionic compound LiH comprises a precise packing of discrete ions.

The calculated radius of Li (Eq. (10.13)) given in Table 10.1 is $2.55606 a_{0}$, and the calculated binding energy is $5.40381 \mathrm{eV}\left(8.65786 \times 10^{-19} J\right)$ (Eq. (10.25)). The $L i-H$ distance, $r_{0}(L i H)$, calculated using Eq. (18.4) with the substitution of $B E(L i)=8.65786 \times 10^{-19} J$ is:

$$
\begin{equation*}
r_{0}(L i H)=2.17 \times 10^{-10} \mathrm{~m} \tag{18.6}
\end{equation*}
$$

The calculated $L i-H$ is in reasonable agreement with the experimental distance of $r_{0}(L i H)=2.04 \times 10^{-10} \mathrm{~m}$ [1] given the experimental difficulty of performing X-ray diffraction on lithium and hydrogen due to the low electron densities. Furthermore, there is a $15 \%$ variation in experimental measurements of the density of LiH [1] that affects the internuclear spacing. Using the $L i-H$ distance and the calculated ionic radii, the lattice structure of $L i H$ is shown in Figure 18.1A.

## SODIUM HYDRIDE

The calculated ionic radii for $\mathrm{Na}^{+}$and $\mathrm{H}^{-}$ions given in Tables 10.8 and 7.2 are $0.560945 a_{0}$ and $1.8660 a_{0}$, respectively. But, the interionic distance can not be the sum of the contact radii since the calculated ionization energies of $\mathrm{Na}^{+}$(Eqs. (10.21210.213)) and $H^{-}$(Eq. (7.69)) are 48.5103 eV and 0.75471 eV , respectively. Furthermore, since the calculated ionization energy (Eqs. (10.226-10.227)) of Na to $\mathrm{Na}^{+}$is 5.12592 eV as shown in Table 10.10 and the ionization energy (Eq. (7.69)) of $H^{-}$to $H$ is $0.75471 \mathrm{eV}\left(1.20836 \times 10^{-19} \mathrm{~J}\right)$, for sufficiently small interionic distances, the sodium ion may be reduced.

Substitution of $B E(N a)=8.21263 \times 10^{-19} J$ into Eq. (18.3) gives the calculated lattice energy of
$\Delta U=N M_{c} B E(N a)=1.74756 N 8.21263 \times 10^{-19} \mathrm{~J}=864.3 \mathrm{~kJ} /$ mole $(206.6 \mathrm{kcal} / \mathrm{mole})$
This agrees well with the experimental lattice energy of $\Delta U=202.0 \mathrm{kcal} /$ mole [2] and confirms that the ionic compound NaH comprises a precise packing of discrete ions.

The calculated radius of $N a$ (Eq. (10.226)) given in Table 10.10 is $2.65432 a_{0}$, and the calculated binding energy is $5.12592 \mathrm{eV}\left(8.21263 \times 10^{-19} J\right)$ (Eqs. (10.226-10.227)). The $N a-H$ distance, $r_{0}(N a H)$, calculated using Eq. (18.4) with the substitution of $B E(N a)=8.21263 \times 10^{-19} J$ is:

$$
\begin{equation*}
r_{0}(\mathrm{NaH})=2.33 \times 10^{-10} \mathrm{~m} \tag{18.8}
\end{equation*}
$$

The calculated $N a-H$ is in good agreement with the experimental distance of $r_{0}(N a H)=2.44 X 10^{-10} \mathrm{~m}$ [2]. Using the $N a-H$ distance and the calculated ionic radii, the lattice structure of $N a H$ is shown in Figure 18.1B.

Figure 18.1. The crystal structures of $M H$ all to the same scale. $\left(L i^{+}=\right.$green, $N a^{+}=$yellow, $K^{+}=$purple, and $H^{-}$and $H^{-}\left(\frac{1}{4}\right)=$ blue). (A) The crystal structure of $L i H$. (B) The crystal structure of NaH. (C) The crystal structure of KH. (D) The crystal structure of $K H\left(\frac{1}{4}\right)$.

## POTASSIUM HYDRIDE

The calculated ionic radii for $K^{+}$and $H^{-}$ions given in Tables 10.17 and 7.2 are $0.85215 a_{0}$ and $1.8660 a_{0}$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of $K^{+}$(Eqs. (10.39910.400)) and $\mathrm{H}^{-}$(Eq. (7.69)) are 31.9330 eV and 0.75471 eV , respectively. Furthermore, since the calculated ionization energy (Eqs. (10.414-10.415)) of $K$ to $K^{+}$is 4.33 eV as shown in Table 10.19 and the ionization energy (Eq. (7.69)) of $\mathrm{H}^{-}$to $H$ is $0.75471 \mathrm{eV}\left(1.20836 \times 10^{-19} \mathrm{~J}\right)$, for sufficiently small interionic distances, the potassium ion may be reduced.

Substitution of $B E(K)=6.93095 \times 10^{-19} J$ into Eq. (18.3) gives the calculated lattice energy of:

$$
\begin{equation*}
\Delta U=N M_{c} B E(K)=1.74756 N 6.93095 \times 10^{-19} J=729.4 \mathrm{~kJ} / \text { mole }(174.3 \mathrm{kcal} / \mathrm{mole}) \tag{18.9}
\end{equation*}
$$

This agrees well with the experimental lattice energy of $\Delta U=177.2 \mathrm{kcal} /$ mole [2] and confirms that the ionic compound $K H$ comprises a precise packing of discrete ions.

The calculated radius of $K$ (Eq. (10.414)) given in Table 10.19 is $3.14515 a_{0}$, and the calculated binding energy is $4.32596 \mathrm{eV}\left(6.93095 \times 10^{-19} J\right)$ (Eqs. (10.414-10.415)). The $K-H$ distance, $r_{0}(K H)$, calculated using Eq. (18.4) with the substitution of $B E(K)=6.93095 \times 10^{-19} J$ is:

$$
\begin{equation*}
r_{0}(K H)=2.86 \times 10^{-10} \mathrm{~m} \tag{18.10}
\end{equation*}
$$

The calculated $K-H$ is in good agreement with the experimental distance of $r_{0}(K H)=2.85 \times 10^{-10} \mathrm{~m}$ [2]. Using the $K-H$ distance and the calculated ionic radii, the lattice structure of $K H$ is shown in Figure 18.1C. An aggregate crystal of unit cells is shown in Figure 18.2.

Figure 18.2. The crystal structure of $K H .\left(K^{+}=\right.$purple and $H^{-}=$blue). (A) Opaque view showing the external geometrical crystal structure of an aggregate of unit cells of $K H$. (B) The crystal structure of $K H$ showing an aggregate of units cells.

## RUBIDIUM AND CESIUM HYDRIDE

As further tests of the boundary condition, the lattice energies of RbH and CsH are given by the product of Avogadro's number, the Madelung constant of $M_{c}=1.74756$, and the binding energy of $R b$ and $C s$ of 4.17713 eV and 3.89390 eV [6], respectively. Using Eq. (18.3), the calculated lattice energy of $R b H$ is:

$$
\begin{equation*}
\Delta U=1.74756 \mathrm{~N}(\mathrm{e} 4.17713 \mathrm{eV})=704.3 \mathrm{~kJ} / \text { mole }=168.3 \mathrm{kcal} / \mathrm{mole} \tag{18.11}
\end{equation*}
$$

This agrees well with the experimental lattice energy of $\Delta U=168.6 \mathrm{kcal} /$ mole [2] and confirms that the ionic compound RbH comprises a precise packing of discrete ions.

Substitution of $B E(R b)=6.6925 \times 10^{-19} J$ into Eq. (18.4) gives the $R b-H$ distance $r_{0}(R b H)$ :

$$
\begin{equation*}
r_{0}(R b H)=2.99 \times 10^{-10} \mathrm{~m} \tag{18.12}
\end{equation*}
$$

The calculated $R b-H$ is in good agreement with the experimental distance of $r_{0}(R b H)=3.02 \times 10^{-10} \mathrm{~m}$ [2].

Using Eq. (18.3), the calculated lattice energy of $C s H$ is: $\Delta U=1.74756 \mathrm{~N}(e 3.89390 \mathrm{eV})=656.6 \mathrm{~kJ} /$ mole $=156.9 \mathrm{kcal} /$ mole $\quad$ (18.13)
This agrees well with the experimental lattice energy of $\Delta U=154.46 \mathrm{kcal} / \mathrm{mole}$ [1] and $\Delta U=162.0 \mathrm{kcal} / \mathrm{mole}$ [2] and confirms that the ionic compound CsH comprises a precise packing of discrete ions.

$$
\begin{align*}
& \text { Substitution of } B E(C s)=6.23872 \times 10^{-19} J \text { into Eq. (18.4) gives the } C s-H \text { distance } r_{0}(C s H) \text { : } \\
& r_{0}(C s H)=3.24 \times 10^{-10} \mathrm{~m} \tag{18.14}
\end{align*}
$$

The calculated $C s-H$ is in good agreement with the experimental distance of $r_{0}(C s H)=3.19 \times 10^{-10} \mathrm{~m}$ [2].

## POTASSIUM HYDRINO HYDRIDE ( $K H\left(\frac{1}{4}\right)$ )

The crystal structure of each alkali hydrino hydride $M H\left(\frac{1}{p}\right)$ is the same as that of the corresponding ordinary alkali hydride except that the radii of the hydride ions $H^{-}\left(\frac{1}{p}\right)$ are each a reciprocal integer times that of ordinary hydride as given by Eq. (7.73). Thus, the lattice energy of $K H\left(\frac{1}{4}\right)$ is the same as that of $K H$ given by Eq. (18.9), and the $K-H\left(\frac{1}{4}\right)$ distance $r_{0}\left(K H\left(\frac{1}{4}\right)\right)$ is the same as that of $K H$ given by Eq. (18.10). Using the $K-H\left(\frac{1}{4}\right)$ distance (Eq. (18.10)), the radius of $K^{+}$ of $0.85215 a_{0}$ (Eq. (10.399)) and the radius of $H^{-}\left(\frac{1}{4}\right)$ of $\frac{1.8660}{4} a_{0}=0.4665 a_{0}$ (Eq. (7.73)), the lattice structure of $K H\left(\frac{1}{4}\right)$ is shown in Figure 18.1D.

## ALKALI-HALIDE CRYSTAL STRUCTURES

The alkali halides ( $M X$ ) are lithium, sodium, potassium, rubidium, and cesium cations, $M^{+}$, with fluoride, chloride, bromide, and iodide anions, $X^{-}$. These saline or salt-like alkali-metal halides each comprise an equal number of alkali cations and halide ions [3] in unit cells of a crystalline lattice. The crystal structure of these ionic compounds is the face-centered cubic NaCl structure except for $C s C l, C s B r$, and $C s I$ that have the $C s C l$ structure at ordinary temperatures and pressures [3]. These close-packed structures are expected since it gives the optimal approach of the positive and negative ions [3]. The NaCl structure comprises face-centered cubes of both $M^{+}$and $X^{-}$ions combined, but offset by half a unit cell length in one direction so that $M^{+}$ions are centered in the edges of the $X^{-}$lattice and vice versa. Each $M^{+}$is surrounded by six nearest neighbor $X^{-}$ ions and vice versa. The resulting unit cell consists of anions (or cations) at the midpoint of each edge and at the center of the cell such that the unit cell contains four cations and four anions. The CsCl structure comprises body-centered cubes of both $\mathrm{M}^{+}$ and $X^{-}$ions wherein $M^{+}$is in the center of cubes of $X^{-}$and vice versa.

## ALKALI-HALIDE LATTICE PARAMETERS AND ENERGIES

The interionic radius of each alkali halide can be derived by considering the radii of the alkali ion and the halide ion, the electron energies at these radii, and the conditions for stability of the ions as the internuclear distance changes and the ions are mutually influenced by the Coulombic fields. Then, the lattice energy is given by the sum over the crystal of the minimum energy of the interacting ion pairs at the radius of minimum approach for which the ions are stable. The sum is further over all Coulombic interactions of the ions of the crystal.

As in the case with alkali hydrides, each alkali halide $M X(M=L i, N a, K, R b, C s$ and $X=F, C l, B r, I)$ is comprised of $M^{+}$and $X^{-}$ions. From Coulomb's law, the lattice energy $\Delta U$ for point charges is given by Eq. (18.1), the Born-Mayer equation. The $M-X$ distance can be calculated from the minimum energy packing of the ions, which is stable. Each ion of the NaCl and CsCl structure is surrounded in a symmetrical octahedral or cubic field of six or four counterions, respectively. From Eq. (18.1), the lattice energy increases as the interionic distance decreases. But, the interionic distance cannot be the sum of the contact radii. This is easily appreciated by considering that the energies of the outer electron of $M^{+}$and the outer electrons of $X^{-}$are very different. For sufficiently small interionic distances, the most energetic reaction that can occur which eliminates the cation and consequently the lattice energy is given by Eq. (18.2). For shorter distances, the spherically symmetrical ${ }^{1} S_{0}$ state of the halide ion is distorted by $M^{+}$, and it is not stable in the ionic crystal when the $M-X$ distance is sufficiently small. To first order, this distance is given by the condition that the total Coulombic energy of attractive terms of $X^{-}$in the field of $M^{+}$as well as the repulsive terms between like-charged ions is equal to the binding energy of $M, B E(M)$, for the cations of the crystal.

As in the case of the alkali hydrides, the lattice energies of alkali halides are determined by the binding energy of the corresponding metal atom. However, for each alkali halide an additional energy term arises corresponding to the effect of the electric field of the metal ion on the magnetic forces and energy of the halide ion. With the binding of the ions in both alkali hydrides and halides, the electric field lines of the metal ions end on those of the negative ions. But, each electron of the hydride ion occupies a symmetrically symmetrical $s$ orbital, and the electrons collectively comprise a filled $s$ shell only such that there is no dipole to interact with the external electric field of the positive ions. Whereas, the outer shell of the halide ions comprise $p$-orbital electrons having magnetic dipoles. These dipoles can interact with the external electric field having dipole components. Thus, the cation-anion separation in ionic compounds having electrons with magnetic dipole moments due to orbital angular momentum is dependent on the effect of the electric field on the magnetic forces of the anion.

Since the magnetic field is a relativistic effect of the electric field and the electron's charge, $e$, charge-to-mass ratio, $\frac{e}{m_{e}}$, angular momentum of $\hbar$, and the magnetic moment of $\mu_{B}$ are relativistically invariant, it is not surprising as shown in the Stark Effect section that the energy, $E_{\text {Stark }}$, of a one-electron atom in an electric field follows from that of a magnetic dipole in a magnetic field Eqs. (2.68-2.69) with the magnetic dipole moment replaced by the electric dipole moment and the magnetic flux replaced by the electric field $\mathbf{E}_{\text {applied }}$. Thus, in alkali halides, the change in Coulombic lattice energy due to the Stark effect is given by the change in magnetic energy of the anion. The Stark-effect energy can be expressed in terms of the magnetic-dipole energy according to Eqs. (2.73-2.75):

$$
\begin{equation*}
E=\mu_{B} B \tag{18.15}
\end{equation*}
$$

The corresponding force $\mathbf{F}_{\text {Stark }}$ on the outer nth electron of the anion is given by Eqs. (7.27-7.31).

$$
\begin{equation*}
\mathbf{F}_{\text {Stark }}=\frac{1}{Z} \frac{\hbar^{2}}{m_{e} r_{n}^{3}} \sqrt{s(s+1)} \mathbf{i}_{r} \tag{18.16}
\end{equation*}
$$

From the radius change and the magnetic energy change, the Stark energy component $\Delta E$ (ionization; $X^{-}$) is calculated. Then, the lattice energy is given by the product of Avogadro's number, the Madelung constant which takes into account all inverse $r_{0}$ (point-like) Coulombic interactions of the crystal, and the sum of $B E(M)$, and $\Delta E$ (ionization; $X^{-}$):

$$
\begin{equation*}
\Delta U=N M_{c}\left(B E(M)+\Delta E\left(\text { ionization } ; X^{-}\right)\right) \tag{18.17}
\end{equation*}
$$

Thus, $M_{c}$ is the factor of stability of forming the crystal from $M^{+}$and $X^{-}$ions. The values for the NaCl and CsCl structures are $M_{c}=1.74756$ and $M_{c}=1.76267$ [3], respectively.

Since the Coulombic potential of the ions is equivalent to that of point charges with some higher order ion-ion-interaction repulsive terms, the $M-X$ distance $r_{0}(M X)$ given using Eq. (18.1), Eq. (18.3), $B E(M)$ and $\Delta E$ (ionization; $\left.X^{-}\right)$is:

$$
\begin{equation*}
r_{0}(M X)=\frac{\frac{Z_{+} Z_{-} e^{2}}{\left(B E(M)+\Delta E\left(\text { ionization } ; X^{-}\right)\right) 4 \pi \varepsilon_{0}}+\sqrt{\left(\frac{Z_{+} Z_{-} e^{2}}{\left(\frac{\left(B E(M)+\Delta E\left(\text { ionization; } X^{-}\right)\right) 4 \pi \varepsilon_{0}}{\left(-\frac{4 \rho Z_{+} Z_{-} e^{2}}{\left(B E(M)+\Delta E\left(\text { ionization; } X^{-}\right)\right) 4 \pi \varepsilon_{0}}\right.}\right.}\right)^{2}}}{2} \tag{18.18}
\end{equation*}
$$

wherein $\rho=0.2 \times 10^{-10} \mathrm{~m}$ for alkali halides [5, 7]. The parameters of the gas-phase halide ions are derived next following the same procedure as that used to solve multielectron atoms.

## RADIUS AND IONIZATION ENERGY OF THE OUTER ELECTRON OF THE FLUORIDE ION

The fluoride atom comprises a nine-electron atom having a central charge of $Z=9$ times that of the proton. There are two indistinguishable spin-paired electrons in an orbitsphere with radii $r_{1}$ and $r_{2}$ both given by Eq. (7.35) (Eq. (10.51)), two indistinguishable spin-paired electrons in an orbitsphere with radii $r_{3}$ and $r_{4}$ both given by Eq. (10.62), and two sets of paired and an unpaired electron in an orbitsphere at $r_{9}$ given by Eq. (10.182). The next electron which binds to form the corresponding ten-electron fluoride ion is attracted by the net magnetic force between the pairing (electron 10) and unpaired (electron 9) to form three pairs of electrons of opposite spin in $p_{x}, p_{y}$, and $p_{z}$ orbitals of an orbitsphere at the same radius $r_{10}$. The resulting electron configuration is $1 s^{2} 2 s^{2} 2 p^{6}$, and the orbital arrangement is:

\[

\]

corresponding to the ground state ${ }^{1} S_{0}$.

Unlike the case of the hydride ion comprising a filled $s$ shell only, the outer shell of the fluoride ion comprises additional orbitals to the one filled by the electron which binds to form the negative ion. The forces are purely magnetic in order to maintain the boundary conditions of an equipotential minimum energy for electrons of the additional orbitals. Thus, the central Coulomb force acts on the outer electron to cause it to bind wherein this electric force on the outer-most electron due to the nucleus and the inner nine electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{\text {ele }}=\frac{(Z-9) e^{2}}{4 \pi \varepsilon_{0} r_{10}^{2}} \mathbf{i}_{\mathbf{r}}=0 \tag{18.20}
\end{equation*}
$$

for $r>r_{9}$ with $Z=9$.
As in the case with the closed-shell $s$ orbitals, the spin-pairing force $\mathbf{F}_{\text {mag }}$ between electron 9 and electron 10 given by Eq. (7.24) is:

$$
\begin{equation*}
\mathbf{F}_{m a g}=\frac{1}{Z} \frac{\hbar^{2}}{m_{e} r_{10}^{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathrm{r}} \tag{18.21}
\end{equation*}
$$

Due to the spin-pairing force the diamagnetic forces and paramagnetic forces are altered relative to those of the isoelectronic neon atom. The energy of the fluoride ion is minimized and the angular momentum is conserved with the pairing of electron ten to fill the $2 p_{y}$ orbital. Then, the orbital angular momentum of each set of the $2 p_{x}$ and $p_{z}$ spin-paired electrons give rise to the diamagnetic force (Eq. (10.82)), $\mathbf{F}_{\text {diamagnetic }}$ :

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic }}=-\left(\frac{1}{3}+\frac{2}{3}\right) \frac{\hbar^{2}}{4 m_{e} r_{10}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}}=-\frac{\hbar^{2}}{4 m_{e} r_{10}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{18.22}
\end{equation*}
$$

From Eq. (10.84), $\mathbf{F}_{\operatorname{mag} 2}$ due to spin and orbital angular momentum is:

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 2}=\frac{1}{Z} \frac{4 \hbar^{2}}{m_{e} r_{10}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{18.23}
\end{equation*}
$$

The outward centrifugal force on electron 10 is balanced by the electric force and the magnetic forces (on electron 10). The radius of the outer electron is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (18.20)), diamagnetic (Eq. (18.22)), and paramagnetic (Eqs. (18.21) and (18.23)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{10}^{2}}{r_{10}}=\frac{(Z-9) e^{2}}{4 \pi \varepsilon_{0} r_{10}^{2}}-\frac{\hbar^{2}}{4 m_{e} r_{10}^{2} r_{3}} \sqrt{s(s+1)}+\frac{4 \hbar^{2}}{Z m_{e} r_{10}^{2} r_{3}} \sqrt{s(s+1)}+\frac{\hbar^{2}}{Z m_{e} r_{10}^{3}} \sqrt{s(s+1)} \tag{18.24}
\end{equation*}
$$

Substitution of $v_{10}=\frac{\hbar}{m_{e} r_{10}}$ (Eq. (1.35)), $Z=9$, and $s=\frac{1}{2}$ into Eq. (18.24) gives:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} r_{10}^{3}}=-\frac{\hbar^{2}}{4 m_{e} r_{10}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{4 \hbar^{2}}{9 m_{e} r_{10}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{\hbar^{2}}{9 m_{e} r_{10}^{3}} \sqrt{\frac{3}{4}} \tag{18.25}
\end{equation*}
$$

$$
\begin{equation*}
r_{10}=\frac{\frac{\hbar^{2}}{m_{e}}\left(1-\frac{\sqrt{\frac{3}{4}}}{9}\right)}{-\frac{\hbar^{2}}{4 m_{e} r_{3}} \sqrt{\frac{3}{4}}+\frac{4 \hbar^{2}}{9 m_{e} r_{3}} \sqrt{\frac{3}{4}}} \tag{18.26}
\end{equation*}
$$

$$
\begin{equation*}
r_{10}=\frac{a_{0}\left(1-\frac{\sqrt{\frac{3}{4}}}{9}\right)}{(4-1) \sqrt{\frac{3}{4}}}, r_{3} \text { in units of } a_{0} \tag{18.27}
\end{equation*}
$$

$$
\left(\frac{4}{9}-\frac{1}{4}\right) \frac{\sqrt{\frac{J}{4}}}{r_{3}}
$$

Substitution of $\frac{r_{3}}{a_{0}}=0.51382$ (Eq. (10.62)) into Eq. (18.27) gives:

$$
\begin{equation*}
r_{10}=2.75769 a_{0} \tag{18.28}
\end{equation*}
$$

The ionization energy of the fluoride ion is given by the magnetic energy of the outer electron calculated by integrating the sum of the diamagnetic (Eq. (18.22)) and paramagnetic (Eqs. (18.21) and (18.23)) forces from $r_{10}$ to $\infty$ :

$$
\begin{equation*}
E_{\text {magwork }}=-\int_{r_{0}}^{\infty}-\frac{\hbar^{2}}{4 m_{e} r_{10}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{4 \hbar^{2}}{Z m_{e} r_{10}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{\hbar^{2}}{Z m_{e} e_{10}^{3}} \sqrt{\frac{3}{4}} d r=\frac{\hbar^{2} \sqrt{\frac{3}{4}}}{m_{e} r_{10}}\left(\left(\frac{4}{Z}-\frac{1}{4}\right) \frac{1}{r_{3}}+\frac{1}{2 Z r_{10}}\right) \tag{18.29}
\end{equation*}
$$

Eq. (18.29) with $r_{3}=0.51382 a_{0}$ (Eq. (10.62)), $r_{10}=2.75769 a_{0}$ (Eq. (18.28)), and $Z=9$ gives:

$$
\begin{equation*}
E\left(\text { ionization } ; F^{-}\right)=3.40603 \mathrm{eV} \tag{18.30}
\end{equation*}
$$

The experimental ionization energy of the fluoride ion is [8]:

$$
\begin{equation*}
E\left(\text { ionization } ; F^{-}\right)=3.4011895 \mathrm{eV} \tag{18.31}
\end{equation*}
$$

## RADIUS AND IONIZATION ENERGY OF THE OUTER ELECTRON OF THE CHLORIDE ION

The chlorine atom comprises a seventeen-electron atom having a central charge of $Z=17$ times that of the proton. There are two indistinguishable spin-paired electrons in an orbitsphere with radii $r_{1}$ and $r_{2}$ both given by Eq. (7.35) (Eq. (10.51)), two indistinguishable spin-paired electrons in an orbitsphere with radii $r_{3}$ and $r_{4}$ both given by Eq. (10.62), three sets of paired electrons in an orbitsphere at $r_{10}$ given by Eq. (10.212), two indistinguishable spin-paired electrons in an orbitsphere with radii $r_{11}$ and $r_{12}$ both given by Eq. (10.255), and two sets of paired and an unpaired electron in an orbitsphere with radius $r_{17}$ given by Eq. (10.363). The next electron which binds to form the corresponding eighteen-electron chloride ion is attracted by the net magnetic force between the pairing (electron 18) and unpaired (electron 17) to form three pairs of electrons of opposite spin in $p_{x}, p_{y}$, and $p_{z}$ orbitals of an orbitsphere at the same radius $r_{18}$. The resulting electron configuration is $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6}$, and the orbital arrangement is:

$$
\begin{equation*}
3 \mathrm{p} \text { state } \tag{18.32}
\end{equation*}
$$

corresponding to the ground state ${ }^{1} S_{0}$.
Unlike the case of the hydride ion, the outer shell of the chloride ion comprises additional orbitals to the one filled by the electron which binds to form the negative ion. The forces are purely magnetic in order to maintain the boundary conditions of an equipotential minimum energy for electrons of the additional orbitals. Thus, the central Coulomb force acts on the outer electron to cause it to bind wherein this electric force on the outer-most electron due to the nucleus and the inner seventeen electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{\text {ele }}=\frac{(Z-17) e^{2}}{4 \pi \varepsilon_{0} r_{18}^{2}} \mathbf{i}_{\mathrm{r}}=0 \tag{18.33}
\end{equation*}
$$

for $r>r_{17}$ with $Z=17$.
As in the case with the closed-shell $s$ orbitals, the spin-pairing force $\mathbf{F}_{m a g}$ between electron 18 and electron 17 given by: Eq. (7.24) is

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag}}=\frac{1}{Z} \frac{\hbar^{2}}{m_{e} r_{18}^{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathrm{r}} \tag{18.34}
\end{equation*}
$$

Due to the spin-pairing force the diamagnetic forces and paramagnetic forces are altered relative to those of the isoelectronic argon atom. The energy of the chloride ion is minimized and the angular momentum is conserved with the pairing of electron eighteen to fill the $3 p_{y}$ orbital when the orbital angular momentum of each set of the $p_{x}, p_{y}$, and $p_{z}$ spin-paired electrons add negatively to cancel. Then, the diamagnetic force (Eq. (10.82)), $\mathbf{F}_{\text {diamagnetic }}$, is zero as in the case of the closed- $p$ shell atom neon:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic }}=0 \tag{18.35}
\end{equation*}
$$

The orbital angular momentum of each set of the $3 p_{x}$ and $p_{z}$ spin-paired electrons and the spin and orbital angular momentum of electrons 17 and 18 that pair upon the binding to fill the $3 p_{y}$ shell give rise to the magnetic force $\mathbf{F}_{\operatorname{mag} 2}$ with the corresponding contributions given by Eqs. (10.83) and (10.84), respectively:

$$
\begin{equation*}
\mathbf{F}_{\text {mag } 2}=(1+1) \frac{1}{Z} \frac{\hbar^{2}}{m_{e} r_{18}^{2} r_{12}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}}+\frac{1}{Z} \frac{4 \hbar^{2}}{m_{e} r_{18}^{2} r_{12}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}}=\frac{1}{Z} \frac{6 \hbar^{2}}{m_{e} r_{18}^{2} r_{12}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{18.36}
\end{equation*}
$$

The outward centrifugal force on electron 18 is balanced by the electric force and the magnetic forces (on electron 18). The radius of the outer electron is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (18.33)), diamagnetic (Eq. (18.35)), and paramagnetic (Eqs. (18.34) and (18.36)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{18}^{2}}{r_{18}}=\frac{(Z-17) e^{2}}{4 \pi \varepsilon_{0} r_{18}^{2}}+\frac{6 \hbar^{2}}{Z m_{e} r_{18}^{2} r_{12}} \sqrt{s(s+1)}+\frac{\hbar^{2}}{Z m_{e} r_{18}^{3}} \sqrt{s(s+1)} \tag{18.37}
\end{equation*}
$$

Substitution of $v_{18}=\frac{\hbar}{m_{e} r_{18}}$ (Eq. (1.35)), $Z=17$, and $s=\frac{1}{2}$ into Eq. (18.37) gives:

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} r_{18}^{3}}=\frac{6 \hbar^{2}}{17 m_{e} r_{18}^{2} r_{12}} \sqrt{\frac{3}{4}}+\frac{\hbar^{2}}{17 m_{e} r_{18}^{3}} \sqrt{\frac{3}{4}}  \tag{18.38}\\
& r_{18}=\frac{\frac{\hbar^{2}}{m_{e}}\left(1-\frac{\sqrt{\frac{3}{4}}}{17}\right)}{\frac{6 \hbar^{2}}{17 m_{e} r_{12}} \sqrt{\frac{3}{4}}}  \tag{18.39}\\
& r_{18}=\frac{a_{0}\left(1-\frac{\sqrt{\frac{3}{4}}}{17}\right)}{6 \sqrt{\frac{3}{4}}}, r_{12} \text { in units of } a_{0}  \tag{18.40}\\
& 17 r_{12}
\end{align*}
$$

Substitution of $\frac{r_{12}}{a_{0}}=0.86545$ (Eq. (10.255)) into Eq. (18.40) gives:

$$
\begin{equation*}
r_{18}=2.68720 a_{0} \tag{18.41}
\end{equation*}
$$

The ionization energy of the chloride ion is given by the magnetic energy of the outer electron calculated by integrating the sum of the diamagnetic (Eq. (18.35)) and paramagnetic (Eqs. (18.34) and (18.36)) forces from $r_{18}$ to $\infty$ :

$$
\begin{equation*}
E_{\text {magwork }}=-\int_{\mathrm{r}_{18}}^{\infty} \frac{6 \hbar^{2}}{Z m_{e} r_{18}^{2} r_{12}} \sqrt{\frac{3}{4}}+\frac{\hbar^{2}}{Z m_{e} r_{18}^{3}} \sqrt{\frac{3}{4}} d r=\frac{\hbar^{2} \sqrt{\frac{3}{4}}}{Z m_{e} r_{18}}\left(\frac{6}{r_{12}}+\frac{1}{2 r_{18}}\right) \tag{18.42}
\end{equation*}
$$

Eq. (18.42) with $r_{12}=0.86545 a_{0}$ (Eq. (10.255)), $r_{18}=2.68720 a_{0}$ (Eq. (18.41)), and $Z=17$ gives:

$$
\begin{equation*}
E\left(\text { ionization } ; \mathrm{Cl}^{-}\right)=3.67238 \mathrm{eV} \tag{18.43}
\end{equation*}
$$

The experimental ionization energy of the chloride ion is [8]:

$$
\begin{equation*}
\text { E(ionization } \left.; \mathrm{Cl}^{-}\right)=3.612724 \mathrm{eV} \tag{18.44}
\end{equation*}
$$

## CHANGE IN THE RADIUS AND IONIZATION ENERGY OF THE FLUORIDE ION DUE TO THE ION FIELD

As in the case of the alkali hydrides, the lattice energies of alkali halides are equivalent to the binding energy of the corresponding metal atom, except for an additional energy term corresponding to the Stark effect of the metal ion on the magnetic forces and energy of the halide ion. The corresponding force $\mathbf{F}_{\text {Stark }}$ on the outer electron of the fluoride ion given by Eq. (18.16) is

$$
\begin{equation*}
\mathbf{F}_{S t a r k}=\frac{1}{Z} \frac{\hbar^{2}}{m_{e} r_{10}^{3}} \sqrt{s(s+1)} \mathbf{i}_{r} \tag{18.45}
\end{equation*}
$$

Then, the outward centrifugal force on electron 10 is balanced by the electric force and the magnetic forces (on electron 10). The radius of the outer electron is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (18.20)), diamagnetic (Eq. (18.22)), and paramagnetic (Eqs. (18.21), (18.23), and (18.45)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{10}^{2}}{r_{10}}=\frac{(Z-9) e^{2}}{4 \pi \varepsilon_{0} r_{10}^{2}}-\frac{\hbar^{2}}{4 m_{e} r_{10}^{2} r_{3}} \sqrt{s(s+1)}+\frac{4 \hbar^{2}}{Z m_{e} r_{10}^{2} r_{3}} \sqrt{s(s+1)}+\frac{2 \hbar^{2}}{Z m_{e} r_{10}^{3}} \sqrt{s(s+1)} \tag{18.46}
\end{equation*}
$$

Substitution of $v_{10}=\frac{\hbar}{m_{e} r_{10}}$ (Eq. (1.35)), $Z=9$, and $s=\frac{1}{2}$ into Eq. (18.46) gives:

$$
\begin{equation*}
r_{10}=\frac{a_{0}\left(1-\frac{2 \sqrt{\frac{3}{4}}}{9}\right)}{\left(\frac{4}{9}-\frac{1}{4}\right) \frac{\sqrt{\frac{3}{4}}}{r_{3}}}, r_{3} \text { in units of } a_{0} \tag{18.47}
\end{equation*}
$$

Substitution of $\frac{r_{3}}{a_{0}}=0.51382$ (Eq. (10.62)) into Eq. (18.47) gives:

$$
\begin{equation*}
r_{10}=2.46408 a_{0} \tag{18.48}
\end{equation*}
$$

The ionization energy of the fluoride ion is given by the magnetic energy of the outer electron calculated by integrating the sum of the diamagnetic (Eq. (18.22)) and paramagnetic (Eqs. (18.21), (18.23), and (18.45)) forces from $r_{10}$ to $\infty$ :

$$
\begin{equation*}
E_{\text {magwork }}=-\int_{r_{10}}^{\infty}-\frac{\hbar^{2}}{4 m_{e} r_{10}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{4 \hbar^{2}}{Z m_{e} r_{10}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{2 \hbar^{2}}{Z m_{e} r_{10}^{3}} \sqrt{\frac{3}{4}} d r=\frac{\hbar^{2} \sqrt{\frac{3}{4}}}{m_{e} r_{10}}\left(\left(\frac{4}{Z}-\frac{1}{4}\right) \frac{1}{r_{3}}+\frac{1}{Z r_{10}}\right) \tag{18.49}
\end{equation*}
$$

Eq. (18.49) with $r_{3}=0.51382 a_{0}$ (Eq. (10.62)), $r_{10}=2.46408 a_{0}$ (Eq. (18.48)), and $Z=9$ gives:

$$
\begin{equation*}
E\left(\text { ionization } ; F^{-}\right)=4.05046 \mathrm{eV} \tag{18.50}
\end{equation*}
$$

The energy change of the fluoride ion $\Delta E$ (ionization; $F^{-}$) due to the Stark effect is given by the difference between Eqs. (18.50) and (18.30):
$\Delta E\left(\right.$ ionization $\left.; F^{-}\right)=4.05046 \mathrm{eV}-3.40603 \mathrm{eV}=0.64444 \mathrm{eV}$

## CHANGE IN THE RADIUS AND IONIZATION ENERGY OF THE CHLORIDE ION DUE TO THE ION FIELD

Similar to the case of the alkali fluorides, the lattice energies of alkali chlorides are equivalent to the binding energy of the corresponding metal atom, except for those cases where there is an additional energy term corresponding to the Stark effect of the metal ion on the magnetic forces and energy of the chloride ion. The selection rules for the Stark effect in one-electron atoms given by Eq. (2.78) is:

$$
\begin{align*}
n & =1,2,3,4, \ldots \\
\ell & =n-1 \\
m_{\ell} & =-\ell,-\ell+1, \ldots, 0, \ldots,+\ell  \tag{18.52}\\
m_{s} & = \pm \frac{1}{2}
\end{align*}
$$

The corresponding energies are given in Table 2.3. For fluoride having an outer 2 p shell:

$$
\begin{equation*}
m_{\ell}=1 \tag{18.53}
\end{equation*}
$$

corresponding to the force $\mathbf{F}_{\text {Stark }}$ on the outer electron of the fluoride ion given by Eq. (18.45) and the binding energy change $\Delta E$ (ionization; $F^{-}$) given by Eq. (18.50).
In the case of the chloride ion, the outer shell is $3 p$. For cations having an outer filled $n s$ or $n p ; n<3$ shell, the interaction of the $3 p$ and $2 p$ shells of $C l^{-}$due to the field of the cation gives rise to a diamagnetic Stark force $\mathbf{F}_{\text {Stark }}$ corresponding to the selection rule:

$$
\begin{equation*}
m_{\ell}=-1 \tag{18.54}
\end{equation*}
$$

wherein the cation's electrons cannot compensate for the diamagnetism by changing orientation. Thus, for $\mathrm{Li}^{+}$and $\mathrm{Na}^{+}$

$$
\begin{equation*}
\mathbf{F}_{\text {Stark }}=-\frac{1}{Z} \frac{\hbar^{2}}{m_{e} r_{18}^{3}} \sqrt{s(s+1)} \mathbf{i}_{r} \tag{18.55}
\end{equation*}
$$

and for $\mathrm{K}^{+}, \mathrm{Rb}^{+}$, and $\mathrm{Cs}^{+}$with ns or $n p ; n \geq 3$

$$
\begin{equation*}
\mathbf{F}_{\text {Stark }}=0 \tag{18.56}
\end{equation*}
$$

Then, the outward centrifugal force on electron 18 is balanced by the electric force and the magnetic forces (on electron 18). The radius of the outer electron is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (18.33)), diamagnetic (Eq. (18.35)), and paramagnetic (Eqs. (18.34), (18.36), and (18.55)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{18}^{2}}{r_{18}}=\frac{(Z-17) e^{2}}{4 \pi \varepsilon_{0} r_{18}^{2}}+\frac{6 \hbar^{2}}{Z m_{e} r_{18}^{2} r_{12}} \sqrt{s(s+1)} \tag{18.57}
\end{equation*}
$$

Substitution of $v_{18}=\frac{\hbar}{m_{e} r_{18}}$ (Eq. (1.35)), $Z=17$, and $s=\frac{1}{2}$ into Eq. (18.57) gives:

$$
\begin{equation*}
r_{18}=\frac{a_{0}}{\frac{6 \sqrt{\frac{3}{4}}}{17 r_{12}}}, r_{12} \text { in units of } a_{0} \tag{18.58}
\end{equation*}
$$

Substitution of $\frac{r_{12}}{a_{0}}=0.86545$ (Eq. (10.255)) into Eq. (18.58) gives:

$$
\begin{equation*}
r_{18}=2.83145 a_{0} \tag{18.59}
\end{equation*}
$$

The ionization energy of the chloride ion is given by the magnetic energy of the outer electron calculated by integrating the sum of the diamagnetic (Eq. (18.35)) and paramagnetic (Eqs. (18.34), (18.36), and (18.55)) forces from $r_{18}$ to $\infty$ :

$$
\begin{equation*}
E_{\text {magwork }}=-\int_{r_{i 8}}^{\infty} \frac{6 \hbar^{2}}{Z m_{e} r_{18}^{2} r_{12}} \sqrt{\frac{3}{4}} d r=\frac{6 \hbar^{2} \sqrt{\frac{3}{4}}}{Z m_{e} r_{18} r_{12}} \tag{18.60}
\end{equation*}
$$

Eq. (18.60) with $r_{12}=0.86545 a_{0}$ (Eq. (10.255)), $r_{18}=2.83145 a_{0}$ (Eq. (18.59)), and $Z=17$ gives:
$E\left(\right.$ ionization; $\left.\mathrm{Cl}^{-}\right)=3.39420 \mathrm{eV}$
For $\mathrm{Li}^{+}$and $\mathrm{Na}^{+}$chlorides, the energy change of the chloride ion $\Delta E$ (ionization; $\mathrm{Cl}^{-}$) due to the Stark effect is given by the difference between Eqs. (18.61) and (18.43).
$\Delta E\left(\right.$ ionization; $\left.\mathrm{Cl}^{-}\right)=3.39420 \mathrm{eV}-3.67238 \mathrm{eV}=-0.27818 \mathrm{eV}$

## LITHIUM FLUORIDE

The calculated ionic radii for $L i^{+}$and $F^{-}$ions in $L i F$ given by Eqs. (10.49) and (18.48) are $0.35566 a_{0}$ and 2.46408a $a_{0}$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of $\mathrm{Li}^{+}$ (Eqs. (7.35), (7.45-7.46), and (7.63)) and $F^{-}$(Eq. (18.50)) are 75.665 eV and 4.05046 eV , respectively. Furthermore, since the calculated ionization energy (Eq. (10.25)) of Li to $\mathrm{Li}^{+}$is 5.40381 eV as shown in Table 10.1 and the ionization energy (Eq. (18.50)) of $F^{-}$to $F$ is 4.05046 eV , for sufficiently small interionic distances, the lithium ion may be reduced.

Substitution of $B E(L i)=8.65786 \times 10^{-19} \mathrm{~J}$ and $\Delta E\left(\right.$ ionization; $\left.F^{-}\right)=0.64444 \mathrm{eV}\left(1.03251 \mathrm{X} 10^{-19} \mathrm{~J}\right)$ (Eq. (18.51)) into Eq. (18.17) gives the calculated lattice energy of:

$$
\begin{align*}
\Delta U & =N M_{c}\left(B E(\text { Li })+\Delta E\left(\text { ionization } ; F^{-}\right)\right) \\
& =1.74756 \mathrm{~N}\left(8.65786 \times 10^{-19} \mathrm{~J}+1.03251 \times 10^{-19} \mathrm{~J}\right)  \tag{18.63}\\
& =1019.8 \mathrm{~kJ} / \text { mole }(243.7 \mathrm{kcal} / \mathrm{mole})
\end{align*}
$$

This agrees well with the experimental lattice energy of $\Delta U=250.7 \mathrm{kcal} /$ mole [9] and confirms that the ionic compound LiF comprises a precise packing of discrete ions.

The $L i-F$ distance, $r_{0}(L i F)$, calculated using Eq. (18.18) with the substitution of $B E(L i)=8.65786 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization $\left.; F^{-}\right)=1.03251 \times 10^{-19} J$ is:

$$
\begin{equation*}
r_{0}(L i F)=2.16 \times 10^{-10} \mathrm{~m} \tag{18.64}
\end{equation*}
$$

The calculated $L i-F$ is in reasonable agreement with the experimental distance of $r_{0}(L i F)=2.01 \times 10^{-10} \mathrm{~m}$ [10]. Using the $L i-F$ distance and the calculated ionic radii, the lattice structure of $L i F$ is shown in Figure 18.3A.

## SODIUM FLUORIDE

The calculated ionic radii for $\mathrm{Na}^{+}$and $\mathrm{F}^{-}$ions in NaF given by Eqs. (10.212) and (18.48) are $0.560945 a_{0}$ and $2.46408 a_{0}$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of $\mathrm{Na}^{+}$ (Eqs. (10.212-10.213)) and $F^{-}$(Eq. (18.50)) are 48.5103 eV and 4.05046 eV , respectively. Furthermore, since the calculated ionization energy (Eqs. (10.226-10.227)) of $\mathrm{Na}^{2}$ to $\mathrm{Na}^{+}$is 5.12592 eV as shown in Table 10.10 and the ionization energy (Eq. (18.50)) of $F^{-}$to $F$ is 4.05046 eV , for sufficiently small interionic distances, the sodium ion may be reduced.

Substitution of $B E(N a)=8.21263 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization; $\left.F^{-}\right)=1.03251 \times 10^{-19} J$ (Eq. (18.51)) into Eq. (18.17) gives the calculated lattice energy of:

$$
\begin{align*}
\Delta U & =N M_{c}\left(B E(N a)+\Delta E\left(\text { ionization } ; F^{-}\right)\right) \\
& =1.74756 \mathrm{~N}\left(8.21263 \times 10^{-19} \mathrm{~J}+1.03251 \times 10^{-19} \mathrm{~J}\right)  \tag{18.65}\\
& =972.95 \mathrm{~kJ} / \text { mole }(232.54 \mathrm{kcal} / \mathrm{mole})
\end{align*}
$$

This agrees well with the experimental lattice energy of $\Delta U=222 \mathrm{kcal} /$ mole [9] and confirms that the ionic compound NaF comprises a precise packing of discrete ions.

The $N a-F$ distance, $r_{0}(N a F)$, calculated using Eq. (18.18) with the substitution of $B E(N a)=8.21263 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization $\left.; F^{-}\right)=1.03251 \times 10^{-19} J$ is:

$$
\begin{equation*}
r_{0}(N a F)=2.28 \times 10^{-10} \mathrm{~m} \tag{18.66}
\end{equation*}
$$

The calculated $N a-F$ is in reasonable agreement with the experimental distance of $r_{0}(N a F)=2.32 \times 10^{-10} \mathrm{~m}$ [10]. Using the $N a-F$ distance and the calculated ionic radii, the lattice structure of $N a F$ is shown in Figure 18.3B.

Figure 18.3. The crystal structures of $M F$ all to the same scale. ( $L i^{+}=$green, $N a^{+}=$yellow, $\mathrm{K}^{+}=$purple, $\mathrm{Rb}^{+}=\mathrm{blue}, \mathrm{Cs}^{+}=$ red, and $F^{-}=$gold). (A) The crystal structure of LiF . (B) The crystal structure of NaF. (C) The crystal structure of KF . (D) The crystal structure of $R b F$. (E) The crystal structure of CsF .

## POTASSIUM FLUORIDE

The calculated ionic radii for $K^{+}$and $F^{-}$ions in $K F$ given by Eqs. (10.399) and (18.48) are $0.85215 a_{0}$ and $2.46408 a_{0}$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of $K^{+}$ (Eqs. (10.399-10.400)) and $F^{-}$(Eq. (18.50)) are 31.9330 eV and 4.05046 eV , respectively. Furthermore, since the calculated ionization energy (Eqs. (10.414-10.415)) of $K$ to $K^{+}$is 4.33 eV as shown in Table 10.19 and the ionization energy (Eq. (18.50)) of $F^{-}$to $F$ is 4.05046 eV , for sufficiently small interionic distances, the potassium ion may be reduced.

Substitution of $B E(K)=6.93095 \times 10^{-19} J$ and $\Delta E$ (ionization; $F^{-}$) $=1.03251 \times 10^{-19} J$ (Eq. (18.51)) into Eq. (18.17) gives the calculated lattice energy of:

$$
\begin{align*}
\Delta U & =N M_{c}\left(B E(K)+\Delta E\left(\text { ionization } ; F^{-}\right)\right) \\
& =1.74756 \mathrm{~N}\left(6.93095 \times 10^{-19} \mathrm{~J}+1.03251 \times 10^{-19} \mathrm{~J}\right)  \tag{18.67}\\
& =838.06 \mathrm{~kJ} / \text { mole }(200.30 \mathrm{kcal} / \text { mole })
\end{align*}
$$

This agrees well with the experimental lattice energy of $\Delta U=198 \mathrm{kcal} /$ mole [9] and confirms that the ionic compound $K F$ comprises a precise packing of discrete ions.

The $K-F$ distance, $r_{0}(K F)$, calculated using Eq. (18.18) with the substitution of $B E(K)=6.93095 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization $\left.; F^{-}\right)=1.03251 \times 10^{-19} J$ is:
$r_{0}(K F)=2.68 \times 10^{-10} \mathrm{~m}$
The calculated $K-F$ is in reasonable agreement with the experimental distance of $r_{0}(K F)=2.67 \times 10^{-10} \mathrm{~m}$ [10]. Using the $K-F$ distance and the calculated ionic radii, the lattice structure of $K F$ is shown in Figure 18.3C.

## RUBIDIUM FLUORIDE

The $R b^{+}$ionic radius calculated using Eq. (10.102) and the experimental ionization energy of $R b^{+}, 27.2895 \mathrm{eV}$ [6] is $0.99714 a_{0}$ and the calculated ionic radius $F^{-}$ions in $R b F$ given by Eq. (18.48) is $2.46408 a_{0}$. But, the interionic distance cannot be the sum of the contact radii since the experimental and calculated ionization energies of $R b^{+}$[6] and $F^{-}$(Eq. (18.50)) are 27.2895 eV and 4.05046 eV , respectively. Furthermore, since the experimental ionization energy of $R b$ to $R b^{+}$is 4.177128 eV [6] and the ionization energy (Eq. (18.50)) of $F^{-}$to $F$ is 4.05046 eV , for sufficiently small interionic distances, the rubidium ion may be reduced.

Substitution of $B E(R b)=6.6925 \times 10^{-19} J$ and $\Delta E$ (ionization; $F^{-}$) $=1.03251 \times 10^{-19} J$ (Eq. (18.51)) into Eq. (18.17) gives the calculated lattice energy of:

$$
\begin{align*}
\Delta U & =N M_{c}\left(B E(R b)+\Delta E\left(\text { ionization } ; F^{-}\right)\right) \\
& =1.74756 \mathrm{~N}\left(6.6925 \times 10^{-19} \mathrm{~J}+1.03251 \times 10^{-19} \mathrm{~J}\right)  \tag{18.69}\\
& =812.97 \mathrm{~kJ} / \text { mole }(194.30 \mathrm{kcal} / \text { mole })
\end{align*}
$$

This agrees well with the experimental lattice energy of $\Delta U=190 \mathrm{kcal} /$ mole [9] and confirms that the ionic compound $R b F$ comprises a precise packing of discrete ions.

The $R b-F$ distance, $r_{0}(R b F)$, calculated using Eq. (18.18) with the substitution of $B E(R b)=6.6925 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization $\left.; F^{-}\right)=1.03251 \times 10^{-19} J$ is:

$$
\begin{equation*}
r_{0}(R b F)=2.77 \times 10^{-10} \mathrm{~m} \tag{18.70}
\end{equation*}
$$

The calculated $R b-F$ is in reasonable agreement with the experimental distance of $r_{0}(R b F)=2.83 \times 10^{-10} \mathrm{~m}$ [10]. Using the $R b-F$ distance and the ionic radii, the lattice structure of $R b F$ is shown in Figure 18.3D.

## CESIUM FLUORIDE

The $\mathrm{Cs}^{+}$ionic radius calculated using Eq. (10.102) and the experimental ionization energy of $\mathrm{Cs}^{+}$, 23.15744 eV [6] is $1.17506 a_{0}$ and the calculated ionic radius $F^{-}$ions in CsF given by Eq. (18.48) is $2.46408 a_{0}$. But, the interionic distance cannot be the sum of the contact radii since the experimental and calculated ionization energies of $\mathrm{Cs}^{+}$[6] and $\mathrm{F}^{-}$(Eq. (18.50)) are 23.15744 eV and 4.05046 eV , respectively. Furthermore, since the experimental ionization energy of $\mathrm{Cs}^{\text {to }} \mathrm{Cs}^{+}$is 3.893905 eV [6] and the ionization energy (Eq. (18.50)) of $F^{-}$to $F$ is 4.05046 eV , for sufficiently small interionic distances, the cesium ion may be reduced.

Substitution of $B E(C s)=6.23872 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization; $\left.F^{-}\right)=1.03251 \times 10^{-19} J$ (Eq. (18.51)) into Eq. (18.17) gives the calculated lattice energy of:

$$
\begin{align*}
\Delta U & =N M_{c}\left(B E(C s)+\Delta E\left(\text { ionization } ; F^{-}\right)\right) \\
& =1.74756 \mathrm{~N}\left(6.23872 \times 10^{-19} \mathrm{~J}+1.03251 \times 10^{-19} \mathrm{~J}\right)  \tag{18.71}\\
& =765.21 \mathrm{~kJ} / \text { mole }(182.89 \mathrm{kcal} / \text { mole })
\end{align*}
$$

This agrees well with the experimental lattice energy of $\Delta U=181 \mathrm{kcal} /$ mole [9] and confirms that the ionic compound CsF comprises a precise packing of discrete ions.

The $C s-F$ distance, $r_{0}(C s F)$, calculated using Eq. (18.18) with the substitution of $B E(C s)=6.23872 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization $\left.; F^{-}\right)=1.03251 \times 10^{-19} J$ is:

$$
\begin{equation*}
r_{0}(C s F)=2.96 \times 10^{-10} \mathrm{~m} \tag{18.72}
\end{equation*}
$$

The calculated $C s-F$ is in reasonable agreement with the experimental distance of $r_{0}(C s F)=3.01 \times 10^{-10} \mathrm{~m}$ [10]. Using the $C s-F$ distance and the ionic radii, the lattice structure of $C s F$ is shown in Figure 18.3E.

## LITHIUM CHLORIDE

The calculated ionic radii for $\mathrm{Li}^{+}$and $\mathrm{Cl}^{-}$ions in LiCl given by Eqs. (10.49) and (18.59) are $0.35566 a_{0}$ and $2.83145 a_{0}$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of $L i^{+}$ (Eqs. (7.35), (7.45-7.46), and (7.63)) and $\mathrm{Cl}^{-}$(Eq. (18.61)) are 75.665 eV and 3.39420 eV , respectively. Furthermore, since the calculated ionization energy (Eq. (10.25)) of Li to $\mathrm{Li}^{+}$is 5.40381 eV as shown in Table 10.1 and the ionization energy (Eq. (18.61)) of $\mathrm{Cl}^{-}$to Cl is 3.39420 eV , for sufficiently small interionic distances, the lithium ion may be reduced.

$$
\text { Substitution of } B E(L i)=8.65786 \times 10^{-19} \mathrm{~J} \text { and } \Delta E\left(\text { ionization; } \mathrm{Cl}^{-}\right)=-0.27818 \mathrm{eV}\left(-4.45691 \times 10^{-20} \mathrm{~J}\right) \quad \text { (Eq. }
$$

(18.62)) into Eq. (18.17) gives the calculated lattice energy of:

$$
\begin{align*}
\Delta U & =N M_{c}\left(B E(L i)+\Delta E\left(\text { ionization } ; \mathrm{Cl}^{-}\right)\right) \\
& =1.74756 \mathrm{~N}\left(8.65786 \times 10^{-19} \mathrm{~J}-4.45691 \times 10^{-20} \mathrm{~J}\right)  \tag{18.73}\\
& =864.24 \mathrm{~kJ} / \text { mole }(206.56 \mathrm{kcal} / \text { mole })
\end{align*}
$$

This agrees well with the experimental lattice energy of $\Delta U=207 \mathrm{kcal} /$ mole [9] and confirms that the ionic compound LiCl comprises a precise packing of discrete ions.

The $\mathrm{Li}-\mathrm{Cl}$ distance, $r_{0}(\mathrm{LiCl})$, calculated using Eq. (18.18) with the substitution of $B E(L i)=8.65786 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization $\left.; \mathrm{Cl}^{-}\right)=-4.45691 \times 10^{-20} \mathrm{~J}$ is:

$$
\begin{equation*}
r_{0}(\mathrm{LiCl})=2.59 \times 10^{-10} \mathrm{~m} \tag{18.74}
\end{equation*}
$$

The calculated $\mathrm{Li}-\mathrm{Cl}$ is in reasonable agreement with the experimental distance of $r_{0}(\mathrm{LiCl})=2.57 \mathrm{X} 10^{-10} \mathrm{~m}$ [10]. Using the $\mathrm{Li}-\mathrm{Cl}$ distance and the calculated ionic radii, the lattice structure of LiCl is shown in Figure 18.4A.

Figure 18.4. The crystal structures of MCl all to the same scale. ( $L i^{+}=$green, $N a^{+}=$yellow, $K^{+}=$purple, $R b^{+}=$blue, $\mathrm{Cs}^{+}=$red, and $\mathrm{Cl}^{-}=$brown). (A) The crystal structure of LiCl . (B) The crystal structure of NaCl . (C) The crystal structure of $K C l$. (D) The crystal structure of RbCl . (E) The crystal structure of $C s C l$.

## SODIUM CHLORIDE

The calculated ionic radii for $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions in NaCl given by Eqs. (10.212) and (18.59) are $0.560945 a_{0}$ and $2.83145 a_{0}$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of $\mathrm{Na}^{+}$ (Eqs. (10.212-10.213)) and $\mathrm{Cl}^{-}$(Eq. (18.61)) are 48.5103 eV and 3.39420 eV , respectively. Furthermore, since the calculated ionization energy (Eqs. (10.226-10.227)) of $\mathrm{Na}^{\text {to }} \mathrm{Na}^{+}$is 5.12592 eV as shown in Table 10.10 and the ionization energy (Eq. (18.61)) of $\mathrm{Cl}^{-}$to Cl is 3.39420 eV , for sufficiently small interionic distances, the sodium ion may be reduced.

Substitution of $B E(N a)=8.21263 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization; $\left.C l^{-}\right)=-4.45691 \times 10^{-20} J$ (Eq. (18.62)) into Eq. (18.17) gives the calculated lattice energy of:

$$
\begin{align*}
\Delta U & =N M_{c}\left(B E(N a)+\Delta E\left(\text { ionization } ; \mathrm{Cl}^{-}\right)\right) \\
& =1.74756 \mathrm{~N}\left(8.21263 \times 10^{-19} \mathrm{~J}-4.45691 \times 10^{-20} \mathrm{~J}\right)  \tag{18.75}\\
& =817.38 \mathrm{~kJ} / \text { mole }(195.36 \mathrm{kcal} / \text { mole })
\end{align*}
$$

This agrees well with the experimental lattice energy of $\Delta U=189 \mathrm{kcal} /$ mole [9] and confirms that the ionic compound NaCl comprises a precise packing of discrete ions.

The $\mathrm{Na}-\mathrm{Cl}$ distance, $r_{0}(\mathrm{NaCl})$, calculated using Eq. (18.18) with the substitution of $B E(N a)=8.21263 \times 10^{-19} J$ and $\Delta E$ (ionization; $\mathrm{Cl}^{-}$) $=-4.45691 \times 10^{-20} J$ is:

$$
\begin{equation*}
r_{0}(\mathrm{NaCl})=2.75 \times 10^{-10} \mathrm{~m} \tag{18.76}
\end{equation*}
$$

The calculated $\mathrm{Na}-\mathrm{Cl}$ is in reasonable agreement with the experimental distance of $r_{0}(\mathrm{NaCl})=2.82 \times 10^{-10} \mathrm{~m}$ [10]. Using the $\mathrm{Na}-\mathrm{Cl}$ distance and the calculated ionic radii, the lattice structure of NaCl is shown in Figure 18.4B.

## POTASSIUM CHLORIDE

The calculated ionic radii for $\mathrm{K}^{+}$and $\mathrm{Cl}^{-}$ions in KCl given by Eqs. (10.399) and (18.59) are $0.85215 a_{0}$ and $2.83145 a_{0}$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of $K^{+}$ (Eqs. (10.399-10.400)) and $\mathrm{Cl}^{-}$(Eq. (18.61)) are 31.9330 eV and 3.39420 eV , respectively. Furthermore, since the calculated ionization energy (Eqs. (10.414-10.415)) of $K$ to $K^{+}$is 4.33 eV as shown in Table 10.19 and the ionization energy (Eq. (18.61)) of $\mathrm{Cl}^{-}$to Cl is 3.39420 eV , for sufficiently small interionic distances, the potassium ion may be reduced.

Substitution of $B E(K)=6.93095 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization; $\left.C l^{-}\right)=-4.45691 \times 10^{-20} J$ (Eq. (18.62)) into Eq. (18.17) gives the calculated lattice energy of:

$$
\begin{align*}
\Delta U & =N M_{c}\left(B E(K)+\Delta E\left(\text { ionization } ; \mathrm{Cl}^{-}\right)\right) \\
& =1.74756 \mathrm{~N}\left(6.93095 \times 10^{-19} \mathrm{~J}-4.45691 \times 10^{-20} \mathrm{~J}\right)  \tag{18.77}\\
& =729.41 \mathrm{~kJ} / \text { mole }(174.33 \mathrm{kcal} / \text { mole })
\end{align*}
$$

This agrees well with the experimental lattice energy of $\Delta U=172 \mathrm{kcal} /$ mole [9] and confirms that the ionic compound KCl comprises a precise packing of discrete ions.

The $\mathrm{K}-\mathrm{Cl}$ distance, $r_{0}(\mathrm{KCl})$, calculated using Eq. (18.18) with the substitution of $B E(K)=6.93095 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization $\left.; \mathrm{Cl}^{-}\right)=-4.45691 \times 10^{-20} \mathrm{~J}$ is:

$$
\begin{equation*}
r_{0}(\mathrm{KCl})=3.11 \times 10^{-10} \mathrm{~m} \tag{18.78}
\end{equation*}
$$

The calculated $\mathrm{K}-\mathrm{Cl}$ is in reasonable agreement with the experimental distance of $r_{0}(\mathrm{KCl})=3.15 \times 10^{-10} \mathrm{~m}$ [10]. Using the $\mathrm{K}-\mathrm{Cl}$ distance and the calculated ionic radii, the lattice structure of KCl is shown in Figure 18.4C.

## RUBIDIUM CHLORIDE

The $R b^{+}$ionic radius calculated using Eq. (10.102) and the experimental ionization energy of $R b^{+}, 27.2895 \mathrm{eV}$ [6] is $0.99714 a_{0}$ and the calculated ionic radius $\mathrm{Cl}^{-}$ions in RbCl given by Eq. (18.59) is $2.83145 a_{0}$. But, the interionic distance cannot be the sum of the contact radii since the experimental and calculated ionization energies of $\mathrm{Rb}^{+}$[6] and $\mathrm{Cl}^{-}$(Eq. (18.61)) are 27.2895 eV and 3.39420 eV , respectively. Furthermore, since the experimental ionization energy of $R b$ to $R b^{+}$is 4.177128 eV [6] and the ionization energy (Eq. (18.61)) of $\mathrm{Cl}^{-}$to Cl is 3.39420 eV , for sufficiently small interionic distances, the rubidium ion may be reduced.

Substitution of $B E(R b)=6.6925 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization; $\left.C l^{-}\right)=-4.45691 \times 10^{-20} J$ (Eq. (18.62)) into Eq. (18.17) gives the calculated lattice energy of:

$$
\begin{align*}
\Delta U & =N M_{c}\left(B E(R b)+\Delta E\left(\text { ionization } ; \mathrm{Cl}^{-}\right)\right) \\
& =1.74756 \mathrm{~N}\left(6.6925 \times 10^{-19} \mathrm{~J}-4.45691 \times 10^{-20} \mathrm{~J}\right)  \tag{18.79}\\
& =704.31 \mathrm{~kJ} / \text { mole }(168.33 \mathrm{kcal} / \text { mole })
\end{align*}
$$

This agrees well with the experimental lattice energy of $\Delta U=166 \mathrm{kcal} /$ mole [9] and confirms that the ionic compound RbCl comprises a precise packing of discrete ions.

The $R b-C l$ distance, $r_{0}(R b C l)$, calculated using Eq. (18.18) with the substitution of $B E(R b)=6.6925 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization; $\left.\mathrm{Cl}^{-}\right)=-4.45691 \times 10^{-20} \mathrm{~J}$ is:

$$
\begin{equation*}
r_{0}(R b C l)=3.23 \times 10^{-10} \mathrm{~m} \tag{18.80}
\end{equation*}
$$

The calculated $\mathrm{Rb}-\mathrm{Cl}$ is in reasonable agreement with the experimental distance of $r_{0}(\mathrm{RbCl})=3.29 \times 10^{-10} \mathrm{~m}$ [10]. Using the $\mathrm{Rb}-\mathrm{Cl}$ distance and the ionic radii, the lattice structure of RbCl is shown in Figure 18.4D.

## CESIUM CHLORIDE

The $\mathrm{Cs}^{+}$ionic radius calculated using Eq. (10.102) and the experimental ionization energy of $\mathrm{Cs}^{+}, 23.15744 \mathrm{eV}$ [6] is $1.17506 a_{0}$ and the calculated ionic radius $C l^{-}$ions in $C s C l$ given by Eq. (18.59) is $2.83145 a_{0}$. But, the interionic distance cannot be the sum of the contact radii since the experimental and calculated ionization energies of $\mathrm{Cs}^{+}$[6] and $\mathrm{Cl}^{-}$(Eq. (18.61)) are 23.15744 eV and 3.39420 eV , respectively. Furthermore, since the experimental ionization energy of $\mathrm{Cs}^{\text {to }} \mathrm{Cs}^{+}$is 3.893905 eV [6] and the ionization energy (Eq. (18.61)) of $\mathrm{Cl}^{-}$to Cl is 3.39420 eV , for sufficiently small interionic distances, the cesium ion may be reduced.

$$
\text { Substitution of } B E(C s)=6.23872 \times 10^{-19} J \text { and } \Delta E\left(\text { ionization; } C l^{-}\right)=-4.45691 \times 10^{-20} J \quad \text { (Eq. (18.62)) into Eq. }
$$

(18.17) gives the calculated lattice energy of:

$$
\begin{align*}
\Delta U & =N M_{c}\left(B E(C s)+\Delta E\left(\text { ionization } ; C l^{-}\right)\right) \\
& =1.76267 N\left(6.23872 \times 10^{-19} \mathrm{~J}-4.45691 \times 10^{-20} \mathrm{~J}\right)  \tag{18.81}\\
& =662.23 \mathrm{~kJ} / \text { mole }(158.28 \mathrm{kcal} / \text { mole })
\end{align*}
$$

This agrees well with the experimental lattice energy of $\Delta U=160 \mathrm{kcal} /$ mole [9] and confirms that the ionic compound CsCl comprises a precise packing of discrete ions.

The $C s-C l$ distance, $r_{0}(C s C l)$, calculated using Eq. (18.18) with the substitution of $B E(C s)=6.23872 \times 10^{-19} J$ and $\Delta E\left(\right.$ ionization; $\left.\mathrm{Cl}^{-}\right)=-4.45691 \times 10^{-20} \mathrm{~J}$ is:

$$
\begin{equation*}
r_{0}(C s C l)=3.49 \times 10^{-10} \mathrm{~m} \tag{18.82}
\end{equation*}
$$

The calculated $\mathrm{Cs}-\mathrm{Cl}$ is in reasonable agreement with the experimental distance of $r_{0}(C s C l)=3.54 X 10^{-10} \mathrm{~m}$ [10]. Using the $\mathrm{Cs}-\mathrm{Cl}$ distance and the ionic radii, the lattice structure of CsCl is shown in Figure 18.4E.

## Chapter 19

## THE NATURE OF THE METALLIC BOND OF ALKALI METALS

## GENERALIZATION OF THE NATURE OF THE METALLIC BOND

Common metals comprise alkali, alkaline earth, and transition elements and have the properties of high electrical and thermal conductivity, opacity, surface luster, ductility, and malleability. From Maxwell's equations, the electric field inside of a metal conductor is zero. As shown in Appendix II, the bound electron exhibits this feature. The charge is confined to a two dimensional layer and the field is normal and discontinuous at the surface. The relationship between the electric field equation and the electron source charge-density function is given by Maxwell's equation in two dimensions [1-3].

$$
\begin{equation*}
\mathbf{n} \bullet\left(\mathbf{E}_{1}-\mathbf{E}_{2}\right)=\frac{\sigma}{\varepsilon_{0}} \tag{19.1}
\end{equation*}
$$

where $\mathbf{n}$ is the normal unit vector, $\mathbf{E}_{1}=0\left(\mathbf{E}_{1}\right.$ is the electric field inside of the MO), $\mathbf{E}_{2}$ is the electric field outside of the MO and $\sigma$ is the surface charge density. The properties of metals can be accounted for the existence of free electrons bound to the corresponding lattice of positive ions. Based on symmetry, the natural coordinates are Cartesian. Then, the problem of the solution of the nature of the metal bonds reduces to a familiar electrostatics problem - the fields and the two-dimensional surface charge density induced on a planar conductor by a point charge such that a zero potential inside of the conductor is maintained according to Maxwell's equations.

There are many examples of charges located near a conductor such as an electron emitted from a cathode or a power line suspended above the conducting earth. Consider a point charge $+e$ at a position $(0,0, d)$ near an infinite planar conductor as shown in Figure 19.1.

Figure 19.1. A point charge above an infinite planar conductor.

With the potential of the conductor set equal to zero, the potential $\Phi$ in the upper half space $(z>0)$ is given by Poisson's equation (Eq. (3.9)), subject to the boundary condition that $\Phi=0$ at $z=0$ and at $z=\infty$. The potential for the point charge in free space is:

$$
\begin{equation*}
\Phi(x, y, z)=\frac{e}{4 \pi \varepsilon_{0}}\left(\frac{1}{\sqrt{x^{2}+y^{2}+(z-d)^{2}}}\right) \tag{19.2}
\end{equation*}
$$

The Poisson solution that meets the boundary condition that the potential is zero at the surface of the infinite planar conductor is
that due to the point charge and an image charge of $-e$ at the position $(0,0,-d)$ as shown in Figure 19.2.
Figure 19.2. A point charge above an infinite planar conductor and the image charge to meet the boundary condition $\Phi=0$ at $z=0$.

The potential for the corresponding electrostatic dipole in the positive half space is:

$$
\Phi(x, y, z)=\left\{\begin{array}{ll}
\frac{e}{4 \pi \varepsilon_{0}}\left(\frac{1}{\sqrt{x^{2}+y^{2}+(z-d)^{2}}}-\frac{1}{\sqrt{x^{2}+y^{2}+(z+d)^{2}}}\right) & \text { for } z>0  \tag{19.3}\\
0 & \text { for } z \leq 0
\end{array}\right\}
$$

The electric field shown in Figure 19.3 is nonzero only in the positive half space and is given by:

$$
\begin{equation*}
\mathbf{E}=-\nabla \Phi=\frac{e}{4 \pi \varepsilon_{0}}\left(\frac{x \mathbf{i}_{x}+y \mathbf{i}_{y}+(z-d) \mathbf{i}_{z}}{\left(x^{2}+y^{2}+(z-d)^{2}\right)^{3 / 2}}-\frac{x \mathbf{i}_{\mathbf{x}}+y \mathbf{i}_{y}+(z+d) \mathbf{i}_{z}}{\left(x^{2}+y^{2}+(z+d)^{2}\right)^{3 / 2}}\right) \tag{19.4}
\end{equation*}
$$

Figure 19.3. Electric field lines from a positive point charge near an infinite planar conductor.

At the surface $(z=0)$, the electric field is normal to the conductor as required by Gauss' and Faraday's laws:

$$
\begin{equation*}
\mathbf{E}(x, y, 0)=\frac{-e d \mathbf{i}_{z}}{2 \pi \varepsilon_{0}\left(x^{2}+y^{2}+d^{2}\right)^{3 / 2}} \tag{19.5}
\end{equation*}
$$

The surface charge density shown in Figure 19.4 is given by Eq. (19.1) with $\mathbf{n}=\mathbf{i}_{z}$ and $\mathbf{E}_{2}=0$ :

$$
\begin{equation*}
\sigma=\frac{-e d}{2 \pi\left(x^{2}+y^{2}+d^{2}\right)^{3 / 2}}=\frac{-e d}{2 \pi\left(\rho^{2}+d^{2}\right)^{3 / 2}} \tag{19.6}
\end{equation*}
$$

Figure 19.4. The surface charge density distribution on the surface of the conduction planar conductor induced by the point charge at the position $(0,0, d)$. (A) The surface charge density $-\sigma(\rho)$ (shown in color-scale relief). (B) The cross-sectional view of the surface charge density.

The total induced charge is given by the integral of the density over the surface:

$$
\begin{align*}
q_{\text {induced }} & =\int \sigma d s \\
& =\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{-e d}{2 \pi\left(x^{2}+y^{2}+d^{2}\right)^{3 / 2}} d y d x \\
& =\frac{-e d}{2 \pi} \int_{-\infty}^{\infty} \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \frac{\cos \theta}{x^{2}+d^{2}} d \theta d x  \tag{19.7}\\
& =\frac{-e d}{\pi} \int_{-\infty}^{\infty} \frac{1}{x^{2}+d^{2}} d x \\
& =\frac{-e d}{\pi} \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \frac{1}{d} d \theta^{\prime} \\
& =-e
\end{align*}
$$

wherein the change of variables $y=\left(x^{2}+d^{2}\right)^{\frac{1}{2}} \tan \theta$ and $x=d \tan \theta^{\prime}$ were used. The total surface charge induced on the surface of the conductor is exactly equal to the negative of the point charge located above the conductor.

Now consider the case where the infinite planar conductor is charged with a surface charge density $\sigma$ corresponding to a total charge of a single electron, $-e$, and the point charge of $+e$ is due to a metal ion $M^{+}$. Then, according to Maxwell's
equations, the potential function of $M^{+}$is given by Eq. (19.3), the electric field between $M^{+}$and $\sigma$ is given by Eqs. (19.419.5), and $\sigma$ is given by Eq. (19.6). The field lines of $M^{+}$end on $\sigma$, and the electric field is zero in the metal and in the negative half space. The potential energy between $M^{+}$and $\sigma$ at the surface ( $z=0$ ) given by the product of Eq. (19.2) and Eq. (19.6) is

$$
\begin{align*}
& V=\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{e}{4 \pi \varepsilon_{0}}\left(\frac{1}{\sqrt{x^{2}+y^{2}+d^{2}}}\right)\left(\frac{-e d}{2 \pi\left(x^{2}+y^{2}+d^{2}\right)^{3 / 2}}\right) d x d y  \tag{19.8}\\
& V=\frac{-e^{2} d}{8 \pi^{2} \varepsilon_{0}} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{1}{\left(x^{2}+y^{2}+d^{2}\right)^{2}} d x d y \tag{19.9}
\end{align*}
$$

Using a change of coordinates to cylindrical and integral \# 47 of Lide [4] gives:

$$
\begin{align*}
& V=\int_{0}^{\infty} \int_{0}^{\infty} \frac{-e^{2} d}{8 \pi^{2} \varepsilon_{0}\left(\rho^{2}+d^{2}\right)^{2}} \rho d \phi d \rho  \tag{19.10}\\
& V=\frac{-e^{2} d}{4 \pi \varepsilon_{0}} \int_{0}^{\infty} \frac{\rho}{\left(\rho^{2}+d^{2}\right)^{2}} d \rho  \tag{19.11}\\
& V=\frac{-e^{2} d}{4 \pi \varepsilon_{0}}\left(\frac{-1}{2\left(\rho^{2}+d^{2}\right)}\right)_{0}^{\infty}  \tag{19.12}\\
& V=\frac{-e^{2}}{4 \pi \varepsilon_{0}(2 d)} \tag{19.13}
\end{align*}
$$

The corresponding force from the negative gradient as well as the integral of the product of the electric field (Eq. (19.5)) and the charge density (Eq. (19.6)) is:

$$
\begin{align*}
\mathbf{F} & =-\nabla V \\
& =\int_{A} \mathbf{E}(x, y, 0) \sigma d A \\
& =\left(\frac{e^{2} d^{2}}{(2 \pi)^{2} \varepsilon_{0}} \mathbf{i}_{z} \int_{0}^{\infty} \int_{0}^{\infty} \frac{\rho d \phi d \rho}{\left(\rho^{2}+d^{2}\right)^{3}}\right. \\
& =2 \pi\left(\frac{e^{2} d^{2}}{(2 \pi)^{2} \varepsilon_{0}} \mathbf{i}_{z} \int_{0}^{\infty} \frac{\rho d \rho}{\left(\rho^{2}+d^{2}\right)^{3}}\right.  \tag{19.14}\\
& =2 \pi\left(\frac{e^{2} d^{2}}{(2 \pi)^{2} \varepsilon_{0}} \mathbf{i}_{z}\right) \frac{1}{4 d^{4}} \\
& =\frac{e^{2}}{8 \pi \varepsilon_{0} d^{2}} \mathbf{i}_{z}
\end{align*}
$$

where $d$ is treated as a variable to be solved as discussed below. The potential is equivalent to that of the charge and its image charge located a distance $2 d$ apart. In addition, the potential and force are equivalent to those of the charge $+e$ and an image charge $\frac{-e}{2}$ located a distance $d$ apart.

In addition to the infinite planar conductor at $z=0$ and the point charge $+e$ at a position $(0,0, d)$ near the infinite planar conductor as shown in Figure 19.1, next consider the introduction of a second infinite planar conductor located at position $z=2 d$ as shown in Figure 19.5.

Figure 19.5. A point charge located between two infinite planar conductors.

As shown, by Kong [5], an image charge at $(0,0,-d)$ meets the boundary condition of zero potential at the bottom plate, but it gives rise to a potential at the top. Similarly, an image charge at $(0,0,3 d)$, meets the boundary condition of zero potential at the top plate, but it gives rise to a potential at the bottom. Satisfaction of the boundary condition of zero potential at both plates due to the presence of the initial real charge requires an infinite series of alternating positive and negative image charges spaced a distance $d$ apart with the potential given by the summation over the real point source and its point-source image charges of $+e$ and $-e$. Since fields superimpose, by adding real charges in a periodic lattice, the image charges cancel except for one per each real charge at a distance $2 d$ apart as in the original case considered in Figure 19.1.

In the real world, the idealized infinite planar conductor is a planar metal sheet experimentally comprised of an essentially infinite lattice of metal ions $M^{+}$and free electrons that provide surface densities $\sigma$ in response to an applied external field such as that due to an external charge of $+e$ due to a metal ion $M^{+}$. Then, it is required that the solutions of the external point charge at an infinite planar conductor are also those of the metal ions and free electrons of metals based on the uniqueness of solutions of Maxwell's equations and the constraint that the individual electrons in a metal conserve the classical physical laws of the macro-scale conductor. In metals, a superposition of planar free electrons given in the Electron in Free Space section replaces the infinite planar conductor. Then, the nature of the metal bond is a lattice of metal ions with field lines that end on the corresponding lattice of electrons wherein each has the two-dimensional charge density $\sigma$ given by Eq. (19.6) to match the boundary conditions of equipotential, minimum energy, and conservation of charge and angular momentum for an ionized electron. Consider an infinite lattice of positive charges in the hollow Cartesian cavities whose walls are the intersecting planes of conductors and that each planar conductor comprises an electron. By Gauss' law, the field lines of each real charge end on each of the $n$ planar-electron walls of the cavity wherein the surface charge density of contribution of each electron is that of image charge of $\frac{-e}{n}$ equidistant across each wall from a given charge $+e$. Then, each electron contributes the charge $\frac{-e}{n}$ to the corresponding ion where each is equivalent electrostatically to an image point charge at twice the distance from the point charge of $+e$ due to $M^{+}$.

Thus, the metallic bond is equivalent to the ionic bond given in the Alkali-Hydride Crystal Structures section with a Madelung constant of one with each negative ion at a position of one half the distance between the corresponding positive ions, but electrostatically equivalent to being positioned at twice this distance, the $M^{+}-M^{+}$-separation distance. The surface charge density of a planar electron having an electric field equivalent to that of image point charge for the corresponding positive ion of the lattice is shown in Figure 19.6.

Figure 19.6. The surface charge density $-\sigma(\rho)$ of a planar electron shown in color scale.

## ALKALI-METAL CRYSTAL STRUCTURES

The alkali metals are lithium ( $L i$ ), sodium ( $N a$ ), potassium $(K)$, rubidium ( $R b$ ), and cesium ( $C s$ ). These alkali metals each comprise an equal number of alkali cations and electrons in unit cells of a crystalline lattice. The crystal structure of these metals is the body-centered cubic CsCl structure [6-8]. This close-packed structure is expected since it gives the optimal approach of the positive ions and negative electrons. For a body-centered cell, there is an identical atom at $x+\frac{a}{2}, y+\frac{a}{2}, z+\frac{a}{2}$ for each atom at $x, y, z$. The structure of the ions with lattice parameters $a=b=c$ and electrons at the diagonal positions centered at $\left(x+\frac{a}{4}, y+\frac{a}{4}, z+\frac{a}{4}\right)$ are shown in Figure 19.7. In this case $n=8$ electron planes per body-centered ion are perpendicular to the four diagonal axes running from each corner of the cube through the center to the opposite corner. The planes intersect these diagonals at one half the distance from each corner to the center of the body-centered atom. The mutual intersection of the planes forms a hexagonal cavity about each ion of the lattice. The length $l_{1}$ to a perpendicular electron plane along the axis from a corner atom to a body-centered atom that is the midpoint of this axis is:

$$
\begin{equation*}
l_{1}=\sqrt{\left(\frac{a}{4}\right)^{2}+\left(\frac{a}{4}\right)^{2}+\left(\frac{a}{4}\right)^{2}}=\frac{a \sqrt{3}}{4} \tag{19.15}
\end{equation*}
$$

The angle $\theta_{d}$ of each diagonal axis from the xy-plane of the unit cell is:

$$
\begin{equation*}
\theta_{d}=\tan ^{-1}\left(\frac{\frac{1}{4}}{\frac{\sqrt{2}}{4}}\right)=35.26^{\circ} \tag{19.16}
\end{equation*}
$$

The angle $\theta_{p}$ from the horizontal to the electron plane that is perpendicular to the diagonal axis is:

$$
\begin{equation*}
\theta_{p}=180^{\circ}-90^{\circ}-35.26^{\circ}=54.73^{\circ} \tag{19.17}
\end{equation*}
$$

The length $l_{3}$ along a diagonal axis in the xy-plane from a corner atom to another at which point an electron plane intersects the xy-plane is:

$$
\begin{equation*}
l_{3}=\frac{l_{1}}{\cos \theta_{d}}=\frac{\frac{a \sqrt{3}}{4}}{\cos \left(35.26^{\circ}\right)}=\frac{\frac{a \sqrt{3}}{4}}{\sqrt{\frac{2}{3}}}=a \frac{3}{4 \sqrt{2}} \tag{19.18}
\end{equation*}
$$

The length $l_{2}$ of the octagonal edge of the electron plane from a body-centered atom to the xy-plane defined by four corner atoms is:

$$
\begin{equation*}
l_{2}=l_{3} \sin \theta_{d}=a \frac{3}{4 \sqrt{2}} \sin \left(35.26^{\circ}\right)=a \frac{3}{4 \sqrt{2}} \frac{1}{\sqrt{3}}=\frac{a}{4} \sqrt{\frac{3}{2}} \tag{19.19}
\end{equation*}
$$

The length $l_{4}$ along the edge of the unit cell in the xy-plane from a corner atom to another at which point an electron plane intersects the xy-plane at this axis is:

$$
\begin{equation*}
l_{4}=\frac{l_{3}}{\cos \left(45^{\circ}\right)}=\frac{a \frac{3}{4 \sqrt{2}}}{\cos \left(45^{\circ}\right)}=\frac{3}{4} a \tag{19.20}
\end{equation*}
$$

The dimensions and angles given by Eqs. (19.15-19.20) are shown in Figure 19.7.
Each $M^{+}$is surrounded by six planar two-dimensional membranes that are comprised of electron density $\sigma$ on which the electric field lines of the positive charges end. The resulting unit cell consists cations at the end of each edge and at the center of the cell with an electron membrane as the perpendicular bisector of the axis from an identical atom at $x+\frac{a}{2}, y+\frac{a}{2}, z+\frac{a}{2}$ for each atom at $x, y, z$ such that the unit cell contains two cations and two electrons. The ions and electrons of the unit cell are also shown in Figure 19.7. The electron membranes exist throughout the metal, but they terminate on metal atomic orbitals or MOs of bonds between metal atoms and other reacted atoms such as the MOs of metal oxide bonds at the edges of the metal.

Figure 19.7. The body-centered cubic lithium metal lattice showing the electrons as planar two-dimensional membranes of zero thickness that are each an equipotential energy surface comprised of the superposition of multiple electrons. (A) and (B) The unit-cell component of the surface charge density of a planar electron having an electric field equivalent to that of an image point charge for each corresponding positive ion of the lattice. (C) Opaque view of the ions and electrons of a unit cell. (D) Transparent view of the ions and electrons of a unit cell.

The interionic radius of each cation and electron membrane can be derived by considering the electron energies at these radii and by calculating the corresponding forces of the electrons with the ions. Then, the lattice energy is given by the sum over the crystal of the energy of the interacting ion and electron pairs at the radius of force balance between the electrons and ions.

For each point charge of $+e$ due to a metal ion $M^{+}$, the planar two-dimensional membrane comprised of electrons contributes a surface charge density $\sigma$ given by Eq. (19.6) corresponding to that of a point image charge having a total charge of a single electron, $-e$. The potential of each electron is double that of Eq. (19.13) since there are two mirror-image $M^{+}$ions per planar electron membrane:

$$
\begin{equation*}
V=\frac{-e^{2}}{4 \pi \varepsilon_{0} d} \tag{19.21}
\end{equation*}
$$

where $d$ is treated as a variable to be solved. The same result is obtained from considering the integral of the product of two times the electric field (Eq. (19.5)) and the charge density (Eq. (19.6)) according to Eq. (19.14). In order to conserve angular momentum and maintain current continuity, the kinetic energy has two components. Since the free electron of a metal behaves as a point mass, one component using Eq. (1.35) with $r=d$ is:

$$
\begin{equation*}
T=\frac{1}{2} m_{e} v^{2}=\frac{1}{2} \frac{\hbar^{2}}{m_{e} d^{2}} \tag{19.22}
\end{equation*}
$$

The other component of kinetic energy is given by integrating the mass density $\sigma_{m}(r)$ (Eq. (19.6)) with $e$ replaced by $m_{e}$ and velocity $v(r)$ (Eq. (1.35)) over their radial dependence $\left(r=\sqrt{x^{2}+y^{2}+z^{2}}=\sqrt{\rho^{2}+d^{2}}\right)$ :

$$
\begin{align*}
T & =\frac{1}{2} \int \sigma v^{2} d A \\
& =\frac{1}{2} \int_{0}^{\infty} \int_{0}^{2 \pi} \frac{m_{e} d}{2 \pi\left(\rho^{2}+d^{2}\right)^{3 / 2}} \frac{\hbar^{2}}{m_{e}^{2}\left(\rho^{2}+d^{2}\right)} \rho d \phi d \rho \\
& =\frac{\hbar^{2} d}{4 \pi m_{e}} \int_{0}^{\infty} \int_{0}^{2 \pi} \frac{\rho}{\left(\rho^{2}+d^{2}\right)^{5 / 2}} d \phi d \rho  \tag{19.23}\\
& =\frac{2 \pi \hbar^{2} d}{4 \pi m_{e}}\left(\frac{-1}{2\left(\frac{3}{2}\right)\left(\rho^{2}+d^{2}\right)^{3 / 2}}\right)_{0}^{\infty} \\
& =\left(\frac{1}{3}\right)\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e} d^{2}}\right)
\end{align*}
$$

where integral \#47 of Lide [4] was used. Thus, the total kinetic energy given by the sum of Eqs. (19.22) and (19.23) is:

$$
\begin{equation*}
T=\left(1+\frac{1}{3}\right)\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e} d^{2}}\right)=\frac{4}{3}\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e} d^{2}}\right) \tag{19.24}
\end{equation*}
$$

Each metal $M(M=L i, N a, K, R b, C s)$ is comprised of $M^{+}$and $e^{-}$ions. The structure of the ions comprises lattice parameters $a=b=c$ and electrons at the diagonal positions centered at $\left(x+\frac{a}{4}, y+\frac{a}{4}, z+\frac{a}{4}\right)$. Thus, the separation distance $d$ between each $M^{+}$and the corresponding electron membrane is:

$$
\begin{equation*}
d=\sqrt{\left(\frac{\Delta x}{2}\right)^{2}+\left(\frac{\Delta y}{2}\right)^{2}+\left(\frac{\Delta z}{2}\right)^{2}}=\sqrt{\left(\frac{1}{4} a\right)^{2}+\left(\frac{1}{4} a\right)^{2}+\left(\frac{1}{4} a\right)^{2}}=\frac{\sqrt{3}}{4} a \tag{19.25}
\end{equation*}
$$

where $\Delta x=\Delta y=\Delta z=\frac{a}{2}$. Thus, the lattice parameter $a$ is given by:

$$
\begin{equation*}
a=\frac{4 d}{\sqrt{3}} \tag{19.26}
\end{equation*}
$$

The molar metal bond energy $E_{D}$ is given by Avogadro's number $N$ times the negative sum of the potential energy, kinetic energy, and ionization or binding energy $(B E(M))$ of $M$ :

$$
\begin{equation*}
E_{D}=-N(V+T+B E(M))=N\left(\frac{e^{2}}{4 \pi \varepsilon_{0} d}-\frac{4}{3}\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e} d^{2}}\right)-B E(M)\right) \tag{19.27}
\end{equation*}
$$

The separation distance $d$ between each $M^{+}$and the corresponding electron membrane is given by the force balance between the outward centrifugal force and the sum of the electric, paramagnetic and diamagnetic forces as given in the ThreeThrough Twenty-Electron Atoms section. The electric force $\mathbf{F}_{\text {ele }}$ corresponding to Eq. (19.21) given by its negative gradient is:

$$
\begin{equation*}
\mathbf{F}_{e l e}=\frac{e^{2}}{4 \pi \varepsilon_{0} d^{2}} \mathbf{i}_{z} \tag{19.28}
\end{equation*}
$$

where inward is taken as the positive direction. The centrifugal force $\mathbf{F}_{\text {centrifugal }}$ is given by negative gradient of Eq. (19.24) times two since the charge and mass density are doubled due to the presence of mirror image $M^{+}$ion pairs across the electron membrane at the origin for any given ion.

$$
\begin{equation*}
\mathbf{F}_{\text {centrifugal }}=-\frac{8}{3} \frac{\hbar^{2}}{m_{e} d^{3}} \mathbf{i}_{z} \tag{19.29}
\end{equation*}
$$

where $d$ is treated as a variable to be solved. In addition, there is an outward spin-pairing force $\mathbf{F}_{\text {mag }}$ between the electron density elements of two opposing ions that is given by Eqs. (7.24) and (10.52):

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag}}=-\frac{1}{Z} \frac{\hbar^{2}}{m_{e} d^{3}} \sqrt{s(s+1)} \mathbf{i}_{z} \tag{19.30}
\end{equation*}
$$

where $s=\frac{1}{2}$. The remaining magnetic forces are determined by the electron configuration of the particular atom as given for the examples of lithium, sodium, and potassium metals in the corresponding sections.

## LITHIUM METAL

For $\mathrm{Li}^{+}$, there are two spin-paired electrons in an orbitsphere with:

$$
\begin{equation*}
r_{1}=r_{2}=a_{0}\left[\frac{1}{2}-\frac{\sqrt{\frac{3}{4}}}{6}\right] \tag{19.31}
\end{equation*}
$$

as given by Eq. (7.35) where $r_{n}$ is the radius of electron $n$ which has velocity $v_{n}$. For the next electron that contributes to the metal-electron membrane, the outward centrifugal force on electron 3 is balanced by the electric force and the magnetic forces (on electron 3). The radius of the metal-band electron is calculated by equating the outward centrifugal force (Eq. (19.29)) to the sum of the electric (Eq. (19.28)) and diamagnetic (Eq. (19.30)) forces as follows:

$$
\begin{align*}
& \frac{8}{3} \frac{\hbar^{2}}{m_{e} d^{3}}=\frac{e^{2}}{4 \pi \varepsilon_{0} d^{2}}-\frac{\hbar^{2}}{Z m_{e} d^{3}} \sqrt{\frac{3}{4}}  \tag{19.32}\\
& d=\left(\frac{8}{3}+\frac{\sqrt{\frac{3}{4}}}{3}\right) a_{0}=2.95534 a_{0}=1.56390 \times 10^{-10} \mathrm{~m} \tag{19.33}
\end{align*}
$$

where $Z=3$. Using Eq. (19.26), the lattice parameter $a$ is:

$$
\begin{equation*}
a=6.82507 a_{0}=3.61167 \times 10^{-10} \mathrm{~m} \tag{19.34}
\end{equation*}
$$

The experimental lattice parameter $a$ [7] is:

$$
\begin{equation*}
a=6.63162 a_{0}=3.5093 \times 10^{-10} \mathrm{~m} \tag{19.35}
\end{equation*}
$$

The calculated $L i-L i$ distance is in reasonable agreement with the experimental distance given the experimental difficulty of performing X-ray diffraction on lithium due to the low electron densities.

Using Eq. (19.27) and the experimental binding energy of lithium, $B E(L i)=5.39172 \mathrm{eV}=8.63849 \times 10^{-19} \mathrm{~J}$ [9], the molar metal bond energy $E_{D}$ is:

$$
\begin{align*}
E_{D} & =N\left(\frac{e^{2}}{4 \pi \varepsilon_{0} 1.56390 \times 10^{-10} m}-\frac{4}{3}\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e}\left(1.56390 \times 10^{-10} m\right)^{2}}\right)-8.63849 \times 10^{-19} \mathrm{~J}\right)  \tag{19.36}\\
& =167.76 \mathrm{~kJ} / \mathrm{mole}
\end{align*}
$$

This agrees well with the experimental lattice [10] energy of:

$$
\begin{equation*}
E_{D}=159.3 \mathrm{~kJ} / \mathrm{mole} \tag{19.37}
\end{equation*}
$$

and confirms that $L i$ metal comprises a precise packing of discrete ions, $L i^{+}$and $e^{-}$. Using the $L i-L i$ and $L i^{+}-e^{-}$ distances and the calculated (Eq. (7.35)) $L i^{+}$ionic radius of $0.35566 a_{0}=0.18821 \AA$, the crystalline lattice structure of the unit cell of Li metal is shown in Figure 19.8, a portion of the crystalline lattice of Li metal is shown in Figure 19.9, and the Li unit cell is shown relative to the other alkali metals in Figure 19.10.

Figure 19.8. The body-centered cubic metal lattice of lithium showing the unit cell of electrons and ions. (A) Diagonal view. (B) Top view.

C

Figure 19.10. The crystalline unit cells of the alkali metals showing each lattice of ions and electrons to the same scale. ( $L i^{+}=$green, $N a^{+}=$yellow, $K^{+}=$purple, $R b^{+}=$blue, $C s^{+}=$red). (A) The crystal structure of $L i$. (B) The crystal structure of $N a$. (C) The crystal structure of $K$. (D) The crystal structure of $R b$. (E) The crystal structure of Cs.

## SODIUM METAL

For $\mathrm{Na}^{+}$, there are two indistinguishable spin-paired electrons in an orbitsphere with radii $r_{1}$ and $r_{2}$ both given by Eq. (7.35) (Eq. (10.51)), two indistinguishable spin-paired electrons in an orbitsphere with radii $r_{3}$ and $r_{4}$ both given by Eq. (10.62), and three sets of paired electrons in an orbitsphere at $r_{10}$ given by Eq. (10.212). For $Z=11$, the next electron which binds to contribute to the metal electron membrane to form the metal bond is attracted by the central Coulomb field and is repelled by diamagnetic forces due to the 3 sets of spin-paired inner electrons.

In addition to the spin-spin interaction between electron pairs, the three sets of $2 p$ electrons are orbitally paired. The metal electron of the sodium atom produces a magnetic field at the position of the three sets of spin-paired $2 p$ electrons. In order for the electrons to remain spin and orbitally paired, a corresponding diamagnetic force, $\mathbf{F}_{\text {diamagnetic } 3}$, on electron eleven from the three sets of spin-paired electrons follows from Eqs. (10.83-10.84) and (10.220):

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 3}=-\frac{1}{Z} \frac{10 \hbar^{2}}{m_{e} d^{3}} \sqrt{s(s+1)} \mathbf{i}_{z} \tag{19.38}
\end{equation*}
$$

corresponding to the $p_{x}$ and $p_{y}$ electrons with no spin-orbit coupling of the orthogonal $p_{z}$ electrons (Eq. (10.84)). The outward centrifugal force on electron 11 is balanced by the electric force and the magnetic forces (on electron 11). The radius of the outer electron is calculated by equating the outward centrifugal force (Eq. (19.29)) to the sum of the electric (Eq. (19.28)) and diamagnetic (Eqs. (19.30) and (19.38)) forces as follows:

$$
\begin{align*}
& \frac{8}{3} \frac{\hbar^{2}}{m_{e} d^{3}}=\frac{e^{2}}{4 \pi \varepsilon_{0} d^{2}}-\frac{\hbar^{2}}{Z m_{e} d^{3}} \sqrt{\frac{3}{4}}-\frac{1}{Z} \frac{10 \hbar^{2}}{m_{e} d^{3}} \sqrt{\frac{3}{4}}  \tag{19.39}\\
& d=\left(\frac{8}{3}+\frac{11 \sqrt{\frac{3}{4}}}{11}\right) a_{0}=3.53269 a_{0}=1.86942 \times 10^{-10} \mathrm{~m} \tag{19.40}
\end{align*}
$$

where $Z=11$ and $s=\frac{1}{2}$. Using Eq. (19.26), the lattice parameter $a$ is:

$$
\begin{equation*}
a=8.15840 a_{0}=4.31724 \times 10^{-10} \mathrm{~m} \tag{19.41}
\end{equation*}
$$

The experimental lattice parameter $a$ [7] is:

$$
\begin{equation*}
a=8.10806 a_{0}=4.2906 \times 10^{-10} \mathrm{~m} \tag{19.42}
\end{equation*}
$$

The calculated $N a-N a$ distance is in good agreement with the experimental distance.
Using Eq. (19.27) and the experimental binding energy of sodium, $B E(N a)=5.13908 \mathrm{eV}=8.23371 \mathrm{X} 10^{-19} \mathrm{~J}$ [9], the molar metal bond energy $E_{D}$ is:

$$
\begin{equation*}
E_{D}=N\left(\frac{e^{2}}{4 \pi \varepsilon_{0} 1.86942 \times 10^{-10} m}-\frac{4}{3}\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e}\left(1.86942 \times 10^{-10} \mathrm{~m}\right)^{2}}\right)-8.23371 \times 10^{-19} \mathrm{~J}\right)=107.10 \mathrm{~kJ} / \mathrm{mole} \tag{19.43}
\end{equation*}
$$

This agrees well with the experimental lattice [10] energy of:

$$
\begin{equation*}
E_{D}=107.5 \mathrm{~kJ} / \mathrm{mole} \tag{19.44}
\end{equation*}
$$

and confirms that Na metal comprises a precise packing of discrete ions, $\mathrm{Na} a^{+}$and $e^{-}$. Using the $\mathrm{Na}-\mathrm{Na}$ and $\mathrm{Na}^{+}-e^{-}$ distances and the calculated (Eq. (10.212)) $N a^{+}$ionic radius of $0.56094 a_{0}=0.29684 \AA$, the crystalline lattice structure of $N a$ metal is shown in Figure 19.10B.

## POTASSIUM METAL

For $K^{+}$, there are two indistinguishable spin-paired electrons in an orbitsphere with radii $r_{1}$ and $r_{2}$ both given by Eq. (7.35) (Eq. (10.51)), two indistinguishable spin-paired electrons in an orbitsphere with radii $r_{3}$ and $r_{4}$ both given by Eq. (10.62), three sets of paired electrons in an orbitsphere at $r_{10}$ given by Eq. (10.212), two indistinguishable spin-paired electrons in an orbitsphere with radii $r_{11}$ and $r_{12}$ both given by Eq. (10.255), and three sets of paired electrons in an orbitsphere with radius $r_{18}$ given by Eq. (10.399). With $Z=19$, the next electron which binds to contribute to the metal electron membrane to form the metal bond is attracted by the central Coulomb field and is repelled by diamagnetic forces due to the 3 sets of spin-paired inner 3p electrons.

The spherically symmetrical closed 3 p shell of nineteen-electron atoms produces a diamagnetic force, $\mathbf{F}_{\text {diamagnetic }}$, that is equivalent to that of a closed s shell given by Eq. (10.11) with the appropriate radii. The inner electrons remain at their initial radii, but cause a diamagnetic force according to Lenz's law that is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic }}=-\frac{\hbar^{2}}{4 m_{e} d^{2} r_{18}} \sqrt{s(s+1)} \mathbf{i}_{z} \tag{19.45}
\end{equation*}
$$

The diamagnetic force, $\mathbf{F}_{\text {diamagnetic } 3}$, on electron nineteen from the three sets of spin-paired electrons given by Eq. (10.409) is

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 3}=-\frac{1}{Z} \frac{12 \hbar^{2}}{m_{e} d^{3}} \sqrt{s(s+1)} \mathbf{i}_{z} \tag{19.46}
\end{equation*}
$$

corresponding to the $3 p_{x}, p_{y}$, and $p_{z}$ electrons.
The outward centrifugal force on electron 19 is balanced by the electric force and the magnetic forces (on electron 19). The radius of the outer electron is calculated by equating the outward centrifugal force (Eq. (19.29)) to the sum of the electric (Eq. (19.28)) and diamagnetic (Eqs. (19.30), (19.45), and (19.46)) forces as follows:

$$
\begin{equation*}
\frac{8}{3} \frac{\hbar^{2}}{m_{e} d^{3}}=\frac{e^{2}}{4 \pi \varepsilon_{0} d^{2}}-\frac{\hbar^{2}}{Z m_{e} d^{3}} \sqrt{\frac{3}{4}}-\frac{1}{Z} \frac{12 \hbar^{2}}{m_{e} d^{3}} \sqrt{\frac{3}{4}}-\frac{\hbar^{2}}{4 m_{e} d^{2} r_{18}} \sqrt{\frac{3}{4}} \tag{19.47}
\end{equation*}
$$

where $s=\frac{1}{2}$.

$$
\begin{equation*}
d=\frac{a_{0}\left(\frac{8}{3}+\frac{13}{Z} \sqrt{\frac{3}{4}}\right)}{(Z-18)-\frac{\sqrt{\frac{3}{4}}}{4 \frac{r_{18}}{a_{0}}}}=\frac{a_{0}\left(\frac{8}{3}+\frac{13}{19} \sqrt{\frac{3}{4}}\right)}{1-\frac{\sqrt{\frac{3}{4}}}{4 \frac{r_{18}}{a_{0}}}} \tag{19.48}
\end{equation*}
$$

Substitution of $\frac{r_{18}}{a_{0}}=0.85215$ (Eq. (10.399) with $Z=19$ ) into Eq. (19.48) gives:

$$
\begin{equation*}
d=4.36934 a_{0}=2.31215 \times 10^{-10} \mathrm{~m} \tag{19.49}
\end{equation*}
$$

Using Eq. (19.26), the lattice parameter $a$ is:

$$
\begin{equation*}
a=10.09055 a_{0}=5.33969 \times 10^{-10} \mathrm{~m} \tag{19.50}
\end{equation*}
$$

The experimental lattice parameter $a$ [7] is:

$$
\begin{equation*}
a=10.05524 a_{0}=5.321 \times 10^{-10} \mathrm{~m} \tag{19.51}
\end{equation*}
$$

The calculated $K-K$ distance is in good agreement with the experimental distance.
Using Eq. (19.27) and the experimental binding energy of potassium, $B E(K)=4.34066 \mathrm{eV}=6.9545 \times 10^{-19} \mathrm{~J}$ [9], the molar metal bond energy $E_{D}$ is:

$$
\begin{equation*}
E_{D}=N\left(\frac{e^{2}}{4 \pi \varepsilon_{0} 2.31215 \times 10^{-10} m}-\frac{4}{3}\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e}\left(2.31215 \times 10^{-10} \mathrm{~m}\right)^{2}}\right)-6.9545 \times 10^{-19} \mathrm{~J}\right)=90.40 \mathrm{~kJ} / \mathrm{mole} \tag{19.52}
\end{equation*}
$$

This agrees well with the experimental lattice [10] energy of

$$
\begin{equation*}
E_{D}=89 \mathrm{~kJ} / \text { mole } \tag{19.53}
\end{equation*}
$$

and confirms that $K$ metal comprises a precise packing of discrete ions, $K^{+}$and $e^{-}$. Using the $K-K$ and $K^{+}-e^{-}$distances and the calculated (Eq. (10.399)) $K^{+}$ionic radius of $0.85215 a_{0}=0.45094 A$, the crystalline lattice structure of $K$ metal is shown in Figure 19.10C.

## RUBIDIUM AND CESIUM METALS

Rubidium and cesium provide further examples of the nature of the bonding in alkali metals. The distance $d$ between each metal ion $M^{+}$and the corresponding electron membrane is calculated from the experimental parameter $a$, and then the molar metal bond energy $E_{D}$ is calculated using Eq. (19.27).

The experimental lattice parameter $a$ [7] for rubidium is:
$a=10.78089 a_{0}=5.705 \times 10^{-10} \mathrm{~m}$
Using Eq. (19.25), the lattice parameter $d$ is:

$$
\begin{equation*}
d=4.66826 a_{0}=2.47034 \times 10^{-10} \mathrm{~m} \tag{19.55}
\end{equation*}
$$

Using Eqs. (19.27) and (19.55) and the experimental binding energy of rubidium, $B E(R b)=4.17713 \mathrm{eV}=6.6925 \times 10^{-19} \mathrm{~J}$ [9], the molar metal bond energy $E_{D}$ is:

$$
\begin{equation*}
E_{D}=N\left(\frac{e^{2}}{4 \pi \varepsilon_{0} 2.47034 \times 10^{-10} m}-\frac{4}{3}\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e}\left(2.47034 \times 10^{-10} \mathrm{~m}\right)^{2}}\right)-6.6925 \times 10^{-19} \mathrm{~J}\right)=79.06 \mathrm{~kJ} / \mathrm{mole} \tag{19.56}
\end{equation*}
$$

This agrees well with the experimental lattice [10] energy of:

$$
\begin{equation*}
E_{D}=80.9 \mathrm{~kJ} / \text { mole } \tag{19.57}
\end{equation*}
$$

and confirms that $R b$ metal comprises a precise packing of discrete ions, $R b^{+}$and $e^{-}$. Using the $R b-R b$ and $R b^{+}-e^{-}$ distances and the $R b^{+}$ionic radius of $0.52766 \AA$ calculated using Eq. (10.102) and the experimental ionization energy of $R b^{+}$, 27.2895 eV [9], the crystalline lattice structure of $R b$ metal is shown in Figure 19.10D.

The experimental lattice parameter $a$ [7] for cesium is:

$$
\begin{equation*}
a=11.60481 a_{0}=6.141 \times 10^{-10} \mathrm{~m} \tag{19.58}
\end{equation*}
$$

Using Eq. (19.25), the lattice parameter $d$ is:

$$
\begin{equation*}
d=5.02503 a_{0}=2.65913 \times 10^{-10} \mathrm{~m} \tag{19.59}
\end{equation*}
$$

Using Eqs. (19.27) and (19.59) and the experimental binding energy of cesium, $B E(C s)=3.8939 \mathrm{eV}=6.23872 \times 10^{-19} \mathrm{~J}$ [9], the molar metal bond energy $E_{D}$ is:

$$
\begin{equation*}
E_{D}=N\left(\frac{e^{2}}{4 \pi \varepsilon_{0} 2.65913 \times 10^{-10} m}-\frac{4}{3}\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e}\left(2.65913 \times 10^{-10} \mathrm{~m}\right)^{2}}\right)-6.23872 \times 10^{-19} \mathrm{~J}\right)=77.46 \mathrm{~kJ} / \mathrm{mole} \tag{19.60}
\end{equation*}
$$

This agrees well with the experimental lattice [10] energy of:

$$
\begin{equation*}
E_{D}=76.5 \mathrm{~kJ} / \text { mole } \tag{19.61}
\end{equation*}
$$

and confirms that $C s$ metal comprises a precise packing of discrete ions, $C s^{+}$and $e^{-}$. Using the $C s-C s$ and $C s^{+}-e^{-}$ distances and the $C s^{+}$ionic radius of $0.62182 \AA$ calculated using Eq. (10.102) and the experimental ionization energy of $C s^{+}$, 23.15744 eV [9], the crystalline lattice structure of Cs metal is shown in Figure 19.10E.

Other metals can be solved in a similar manner. Iron, for example, is also a body-centered cubic lattice, and the solution of the lattice spacing and energies are given by Eqs. (19.21-19.30). The parameter $d$ is given by the iron force balance which has a corresponding form to those of alkali metals such as that of lithium given by Eqs. (19.32-19.35). In addition, the changes in radius and energy of the second $4 s$ electron due to the ionization of the first of the two $4 s$ electrons to the metal band is calculated in the similar manner as those of the atoms of diatomic molecules such as $N_{2}$ given by Eqs. (19.621-19.632). This energy term is added to those of Eq. (19.27) to give the molar metal bond energy $E_{D}$.

## PHYSICAL IMPLICATIONS OF THE NATURE OF FREE ELECTRONS IN METALS

The extension of the free-electron membrane throughout the crystalline lattice is the reason for the high thermal and electrical conductivity of metals. Electricity can be conduced on the extended electron membranes by the application of an electric field and a connection with a source of electrons to maintain current continuity. Heat can be transferred by radiation or by collisions, or by infrared-radiation-induced currents propagated through the crystal. The surface luster and opacity is due to the reflection of electromagnetic radiation by mirror currents on the surfaces of the free-planar electron membranes. Ductility and malleability result from the feature that the field lines of a given ion end on the induced electron surface charge of the planar, perfectly conducting electron membrane. Thus, layers of the metal lattice can slide over each other without juxtaposing charges of the same sign which causes ionic crystals to fracture.

The electrons in metals have surface-charge distributions that are merely equivalent to the image charges of the ions. When there is vibration of the ions, the thermal electron kinetic energy can be directed through channels of least resistance from collisions. The resulting kinetic energy distribution over the population of electrons can be modeled using Fermi Dirac statistics
wherein the specific heat of a metal is dominated by the motion of the ions since the electrons behave as image charges. Based on the physical solution of the nature of the metallic bond, the small electron contribution to the specific heat of a metal is predicted to be proportional to the ratio of the temperature to the electron kinetic energy [11]. Based on Fermi-Dirac statistics, the electron contribution to the specific heat of a metal given by Eq. (23.68) is:

$$
\begin{equation*}
C_{V e}=\frac{\pi^{2}}{2}\left(\frac{k T}{\varepsilon_{F}}\right) R \tag{19.62}
\end{equation*}
$$

Now that the true structure of metals has been solved, it is interesting to relate the Fermi energy to the electron kinetic energy. The relationships between the electron velocity, the de Broglie wavelength, and the lattice spacing used calculate the Fermi energy in the Electron-Energy Distribution section are also used in the kinetic energy derivation. The Fermi energy given by Eq. (23.61) is:

$$
\begin{equation*}
\varepsilon_{F}=\frac{h^{2}}{2 m}\left(\frac{3 N}{8 \pi V}\right)^{2 / 3}=\frac{h^{2}}{2 m_{e}}\left(\frac{3}{8 \pi}\right)^{2 / 3} n^{2 / 3} \tag{19.63}
\end{equation*}
$$

where the electron density parameter for alkali metals is two electrons per body-centered cubic cell of lattice spacing $a$. Since in the physical model, the field lines of two mirror-image ions $M^{+}$end on opposite sides per section of the two-dimensional electron membrane, the kinetic energy equivalent to the Fermi energy is twice that given by Eq. (19.24). Then, the ratio $R_{\varepsilon_{F} / T}$ of the Fermi energy to the kinetic energy provides a comparison of the statistical model to the solution of the nature of the metallic bond in the determination of electron contribution to the specific heat:

$$
\begin{equation*}
R_{\varepsilon_{F} / T}=\frac{\varepsilon_{F}}{T}=\frac{\frac{h^{2}}{2 m_{e}}\left(\frac{3}{8 \pi}\right)^{2 / 3} n^{2 / 3}}{\frac{8}{3}\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e} d^{2}}\right)}=\frac{\frac{h^{2}}{2 m_{e}}\left(\frac{3}{8 \pi}\right)^{2 / 3}\left(\frac{2}{a^{3}}\right)^{2 / 3}}{\frac{8}{3}\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e} d^{2}}\right)}=\frac{\frac{h^{2}}{2 m_{e}}\left(\frac{3}{8 \pi}\right)^{2 / 3}\left(\frac{2}{\left(\frac{4 d}{\sqrt{3}}\right)^{3}}\right)^{2 / 3}}{\left(\frac{8}{3}\right)\left(\frac{1}{2 \pi}\right)^{2}\left(\frac{h^{2}}{2 m_{e} d^{2}}\right)}=1.068 \tag{19.64}
\end{equation*}
$$

where Eq. (19.26) was used to convert the parameter $a$ to $d$.
From the physical nature of the current, the electrical and thermal conductivities corresponding to the currents can be determined. The electrical current is classically given by

$$
\begin{equation*}
i=e v=\sigma \frac{\varepsilon_{F}}{h e} \tag{19.65}
\end{equation*}
$$

where the energy and angular momentum of the conduction electrons are quantized according to $\hbar$ and Planck's equation (Eq. (4.8)), respectively. From Eq. (19.65), the electrical conductivity is given by:

$$
\begin{equation*}
\sigma=\frac{e^{2} h \nu}{\varepsilon_{F}} \tag{19.66}
\end{equation*}
$$

where $v$ is the frequency of the unit current carried by each electron. The thermal current is also carried by the kinetic energy of the electron plane waves. Since there are two degrees of freedom in the plane of each electron rather than three, the thermal conductivity $\kappa$ is given by:

$$
\begin{equation*}
\kappa=\frac{2}{3} \frac{C_{V e}}{N_{0} h}=\frac{\pi^{2}}{3}\left(\frac{k_{B}^{2} T}{\varepsilon_{F} / h}\right) \tag{19.67}
\end{equation*}
$$

The Wiedemann-Franz law gives the relationship of the thermal conductivity $\kappa$ to the electrical conductivity $\sigma$ and absolute temperature $T$. Thus, using Eqs. (19.66-19.67), the constant $L_{0}$ is given by:

$$
\begin{equation*}
L_{0}=\frac{\kappa}{\sigma T}=\frac{\frac{\pi^{2}}{3}\left(\frac{h k_{B}^{2}}{\varepsilon_{F}}\right)}{\frac{h e^{2}}{\varepsilon_{F}}}=\frac{\pi^{2}}{3}\left(\frac{k_{B}}{e}\right)^{2} \tag{19.68}
\end{equation*}
$$

From Eqs. (19.64) and (19.68), the statistical model is reasonably close to the physical model to be useful in modeling the specific-heat contribution of electrons in metals based on their inventory of thermal energy and the thermal-energy distribution in the crystal. However, the correct physical nature of the current carriers comprising two-dimensional electron planes is required in cases where the simplistic statistical model fails as in the case of the anisotropic violation of the Wiedemann-Franz law [1213].

Semiconductors comprise covalent bonds wherein the electrons are of sufficiently high energy that excitation creates an ion and a free electron. The free electron forms a membrane as in the case of metals. This membrane has the same planar structure throughout the crystal. This feature accounts for the high conductivity of semiconductors when the electrons are excited by the application of external fields or electromagnetic energy that causes ion-pair ( $M^{+}-e^{-}$) formation.

Superconductors comprise free-electron membranes wherein current flows in a reduced dimensionality of two or one dimensions with the bonding being covalent along the remaining directions such that electron scattering from other planes does not interfere with the current flow. In addition, the spacing of the electrons along the membrane is such that the energy is bandpassed with respect to magnetic interactions of conducting electrons as given in the superconductivity section.

## Chapter 20

## SILICON MOLECULAR FUNCTIONAL GROUPS AND MOLECULES

## GENERAL CONSIDERATIONS OF THE SILICON MOLECULAR BOND

Silane molecules comprising an arbitrary number of atoms can be solved using similar principles and procedures as those used to solve organic molecules of arbitrary length and complexity. Silanes can be considered to be comprised of functional groups such as $\mathrm{SiH}_{3}, \mathrm{SiH}_{2}, \mathrm{SiH}, \mathrm{Si}-\mathrm{Si}$, and $\mathrm{C}-\mathrm{Si}$. The solutions of these functional groups or any others corresponding to the particular silane can be conveniently obtained by using generalized forms of the force balance equation given in the Force Balance of the $\sigma$ MO of the Carbon Nitride Radical section for molecules comprised of silicon and hydrogen only and the geometrical and energy equations given in the Derivation of the General Geometrical and Energy Equations of Organic Chemistry section for silanes further comprised of heteroatoms such as carbon. The appropriate functional groups with their geometrical parameters and energies can be added as a linear sum to give the solution of any silane.

## SILANES ( $\mathrm{Si}_{n} \mathrm{H}_{2 n+2}$ )

As in the case of carbon, the bonding in the silicon atom involves four $s p^{3}$ hybridized orbitals formed from the $3 p$ and $3 s$ electrons of the outer shells. $\mathrm{Si}-\mathrm{Si}$ and $\mathrm{Si}-\mathrm{H}$ bonds form between $\mathrm{Si} 3 s p^{3} \mathrm{HOs}$ and between a $\mathrm{Si} 3 s p^{3} \mathrm{HO}$ and a $H 1 s \mathrm{AO}$ to yield silanes. The geometrical parameters of each $\mathrm{Si}-\mathrm{Si}$ and $\mathrm{SiH}_{n=1,2,3}$ functional group is solved from the force balance equation of the electrons of the corresponding $\sigma-\mathrm{MO}$ and the relationships between the prolate spheroidal axes. Then, the sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $\mathrm{Si} 3 \mathrm{sp}{ }^{3}$ shell as in the case of the corresponding carbon molecules. As in the case of ethane given in the Ethane Molecule section, the energy of the $\mathrm{Si}-\mathrm{Si}$ functional group is determined for the effect of the donation of $25 \%$ electron density from each participating $\mathrm{Si} 3 s p^{3} \mathrm{HO}$ to the $\mathrm{Si}-\mathrm{Si}$-bond MO.

The energy of silicon is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). A minimum energy is achieved while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical $(O H)$ section with the donation of $75 \%$ electron density from the participating $\mathrm{Si} 3 s p^{3} \mathrm{HO}$ to each $\mathrm{Si}-\mathrm{H}$-bond MO. As in the case of acetylene given in the Acetylene Molecule section, the energy of each $\mathrm{Si}-H_{n}$ functional group is determined for the effect of the charge donation.

The $3 s p^{3}$ hybridized orbital arrangement after Eq. (13.422) is:

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the four electrons. The sum $E_{T}\left(S i, 3 s p^{3}\right)$ of experimental energies [1] of $\mathrm{Si}, \mathrm{Si}^{+}, \mathrm{Si}^{2+}$, and $\mathrm{Si}^{3+}$ is:

$$
\begin{equation*}
E_{T}\left(S i, 3 s p^{3}\right)=45.14181 \mathrm{eV}+33.49302 \mathrm{eV}+16.34584 \mathrm{eV}+8.15168 \mathrm{eV}=103.13235 \mathrm{eV} \tag{20.2}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 s p^{3}}$ of the Si3sp ${ }^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{3 s p^{3}}=\sum_{n=10}^{13} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 103.13235 \mathrm{eV})}=\frac{10 e^{2}}{8 \pi \varepsilon_{0}(e 103.13235 \mathrm{eV})}=1.31926 a_{0} \tag{20.3}
\end{equation*}
$$

where $Z=14$ for silicon. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(S i, 3 s p^{3}\right)$ of the outer electron of the Si3sp ${ }^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(S i, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.31926 a_{0}}=-10.31324 \mathrm{eV} \tag{20.4}
\end{equation*}
$$

During hybridization, one of the spin-paired $3 s$ electrons is promoted to the $S i 3 s p^{3}$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (15.15) at the initial radius of the $3 s$ electrons. From Eq. (10.255) with $Z=14$, the radius $r_{12}$ of the Si3s shell is:

$$
\begin{equation*}
r_{12}=1.25155 a_{0} \tag{20.5}
\end{equation*}
$$

Using Eqs. (15.15) and (20.5), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{12}\right)^{3}}=\frac{8 \pi \mu_{o} \mu_{B}^{2}}{\left(1.25155 a_{0}\right)^{3}}=0.05836 \mathrm{eV} \tag{20.6}
\end{equation*}
$$

Using Eqs. (20.4) and (20.6), the energy $E\left(S i, 3 s p^{3}\right)$ of the outer electron of the $S i 3 s p^{3}$ shell is

$$
\begin{equation*}
E\left(S i, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{12}\right)^{3}}=-10.31324 \mathrm{eV}+0.05836 \mathrm{eV}=-10.25487 \mathrm{eV} \tag{20.7}
\end{equation*}
$$

Next, consider the formation of the Si-Si-bond MO of silanes wherein each silicon atom has a $S i 3 s p^{3}$ electron with an energy given by Eq. (20.7). The total energy of the state of each silicon atom is given by the sum over the four electrons. The $\operatorname{sum} E_{T}\left(S i_{\text {sliane }}, 3 s p^{3}\right)$ of energies of $S i 3 s p^{3}$ (Eq. (20.7)), $S i^{+}, S i^{2+}$, and $S i^{3+}$ is:

$$
\begin{align*}
E_{T}\left(S i_{\text {sllane }}, 3 s p^{3}\right) & =-\left(45.14181 \mathrm{eV}+33.49302 \mathrm{eV}+16.34584 \mathrm{eV}+E\left(S i, 3 s p^{3}\right)\right)  \tag{20.8}\\
& =-(45.14181 \mathrm{eV}+33.49302 \mathrm{eV}+16.34584 \mathrm{eV}+10.25487 \mathrm{eV})=-105.23554 \mathrm{eV}
\end{align*}
$$

where $E\left(S i, 3 s p^{3}\right)$ is the sum of the energy of $S i,-8.15168 \mathrm{eV}$, and the hybridization energy.
The sharing of electrons between two $S i 3 s p^{3} \mathrm{HO}$ to form a Si -Si-bond MO permits each participating orbital to decrease in size and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each Si3sp ${ }^{3}$ HO donates an excess of $25 \%$ of its electron density to the $S i-S i$-bond MO to form an energy minimum. By considering this electron redistribution in the silane molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{\text {silanessp }}$ of the Si3sp ${ }^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18):

$$
\begin{equation*}
r_{\text {silanessp }}=\left(\sum_{n=10}^{13}(Z-n)-0.25\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 105.23554 \mathrm{eV})}=\frac{9.75 e^{2}}{8 \pi \varepsilon_{0}(e 105.23554 \mathrm{eV})}=1.26057 a_{0} \tag{20.9}
\end{equation*}
$$

Using Eqs. (15.19) and (20.9), the Coulombic energy $E_{\text {Coulomb }}\left(S_{\text {silame }}, 3 s p^{3}\right)$ of the outer electron of the $S i 3 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(S i_{s_{\text {slane }},}, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {silane } 3 \text { sp }}{ }^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.26057 a_{0}}=-10.79339 \mathrm{eV} \tag{20.10}
\end{equation*}
$$

During hybridization, one of the spin-paired $3 s$ electrons is promoted to the $S i 3 s p^{3}$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (20.6). Using Eqs. (20.6) and (20.10), the energy $E\left(S i_{\text {silane }}, 3 s p^{3}\right)$ of the outer electron of the $S i 3 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(S i_{\text {silane }}, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {silanesesp3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{12}\right)^{3}}=-10.79339 \mathrm{eV}+0.05836 \mathrm{eV}=-10.73503 \mathrm{eV} \tag{20.11}
\end{equation*}
$$

Thus, $E_{T}\left(S i-S i, 3 s p^{3}\right)$, the energy change of each $S i 3 s p^{3}$ shell with the formation of the $S i-S i$-bond MO is given by the difference between Eq. (20.11) and Eq. (20.7):

$$
\begin{equation*}
E_{T}\left(S i-S i, 3 s p^{3}\right)=E\left(S i_{\text {silune }}, 3 s p^{3}\right)-E\left(S i, 3 s p^{3}\right)=-10.73503 \mathrm{eV}-(-10.25487 \mathrm{eV})=-0.48015 \mathrm{eV} \tag{20.12}
\end{equation*}
$$

Next, consider the formation of the $S i-H$-bond MO of silanes wherein each silicon atom contributes a $S i 3 s p^{3}$ electron having the sum $E_{T}\left(S i_{s i l u m e}, 3 s p^{3}\right)$ of energies of $S i 3 s p^{3}$ (Eq. (20.7)), $S i^{+}, S i^{2+}$, and $S i^{3+}$ given by Eq. (20.8). Each $S i-H$-bond MO of each functional group $S i H_{n=1,2,3}$ forms with the sharing of electrons between each $S i 3 s p^{3}$ HO and each $H 1 s$ AO. As in the case of $\mathrm{C}-\mathrm{H}$, the $\mathrm{H}_{2}$-type ellipsoidal MO comprises $75 \%$ of the $\mathrm{Si}-H$-bond MO according to Eq. (13.429). Furthermore, the donation of electron density from each Si3sp ${ }^{3}$ HO to each $\mathrm{Si}-H$-bond MO permits the participating orbital to decrease in size and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each Si3sp ${ }^{3}$ HO donates an excess of $75 \%$ of its electron density to the $S i-H$-bond MO to form an energy minimum. By considering this electron redistribution in the silane molecule as well as the fact that the central field decreases by an integer for each successive
electron of the shell, the radius $r_{\text {silanesesp }}$ of the $S i 3 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$
\begin{equation*}
r_{\text {silane3sp }}=\left(\sum_{n=10}^{13}(Z-n)-0.75\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 105.23554 \mathrm{eV})}=\frac{9.25 e^{2}}{8 \pi \varepsilon_{0}(e 105.23554 \mathrm{eV})}=1.19592 a_{0} \tag{20.13}
\end{equation*}
$$

Using Eqs. (15.19) and (20.13), the Coulombic energy $E_{\text {Coulomb }}\left(S i_{\text {silane }}, 3 s p^{3}\right)$ of the outer electron of the $S i 3 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(S i_{\text {silane }}, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {silanessp }}{ }^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.19592 a_{0}}=-11.37682 \mathrm{eV} \tag{20.14}
\end{equation*}
$$

During hybridization, one of the spin-paired $3 s$ electrons is promoted to the $S i 3 s p^{3}$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (20.6). Using Eqs. (20.6) and (20.14), the energy $E\left(S i_{\text {silane }}, 3 s p^{3}\right)$ of the outer electron of the $S i 3 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(S i_{\text {silane }}, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {silane } 3 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{12}\right)^{3}}=-11.37682 \mathrm{eV}+0.05836 \mathrm{eV}=-11.31845 \mathrm{eV} \tag{20.15}
\end{equation*}
$$

Thus, $E_{T}\left(S i-H, 3 s p^{3}\right)$, the energy change of each $S i 3 s p^{3}$ shell with the formation of the $S i-H$-bond MO is given by the difference between Eq. (20.15) and Eq. (20.7):

$$
\begin{equation*}
E_{T}\left(S i-H, 3 s p^{3}\right)=E\left(S i_{\text {silane }}, 3 s p^{3}\right)-E\left(S i, 3 s p^{3}\right)=-11.31845 \mathrm{eV}-(-10.25487 \mathrm{eV})=-1.06358 \mathrm{eV} \tag{20.16}
\end{equation*}
$$

Silane $\left(\mathrm{SiH}_{4}\right)$ involves only $\mathrm{Si}-\mathrm{H}$-bond MOs of equivalent tetrahedral structure to form a minimum energy surface involving a linear combination of all four hydrogen MOs. Here, the donation of electron density from the Si3sp ${ }^{3} \mathrm{HO}$ to each $\mathrm{Si}-\mathrm{H}$-bond MO permits the participating orbital to decrease in size and energy as well. However, given the resulting continuous electron-density surface and the equivalent MOs, the Si3sp ${ }^{3} \mathrm{HO}$ donates an excess of $100 \%$ of its electron density to the $\mathrm{Si}-\mathrm{H}$-bond MO to form an energy minimum. By considering this electron redistribution in the silane molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{\text {silane3sp }}$ of the $S i 3 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18):

$$
\begin{equation*}
r_{\text {silane } 3 \text { sp }}{ }^{3}=\left(\sum_{n=10}^{13}(Z-n)-1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 105.23554 \mathrm{eV})}=\frac{9 e^{2}}{8 \pi \varepsilon_{0}(e 105.23554 \mathrm{eV})}=1.16360 a_{0} \tag{20.17}
\end{equation*}
$$

Using Eqs. (15.19) and (20.17), the Coulombic energy $E_{\text {Coulomb }}\left(S i_{\text {silane }}, 3 s p^{3}\right)$ of the outer electron of the $S i 3 s p^{3}$ shell is

$$
\begin{equation*}
E_{\text {Coulomb }}\left(S i_{\text {silane }}, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {silanessp }}{ }^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.16360 a_{0}}=-11.69284 \mathrm{eV} \tag{20.18}
\end{equation*}
$$

During hybridization, one of the spin-paired $3 s$ electrons is promoted to the $S i 3 s p^{3}$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (20.6). Using Eqs. (20.6) and (20.18), the energy $E\left(S i_{\text {silane }}, 3 s p^{3}\right)$ of the outer electron of the $\mathrm{Si} 3 \mathrm{sp}{ }^{3}$ shell is:

$$
\begin{equation*}
E\left(S i_{\text {silane }}, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {silanessp }}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{12}\right)^{3}}=-11.69284 \mathrm{eV}+0.05836 \mathrm{eV}=-11.63448 \mathrm{eV} \tag{20.19}
\end{equation*}
$$

Thus, $E_{T}\left(S i-H, 3 s p^{3}\right)$, the energy change of each $S i 3 s p^{3}$ shell with the formation of the $S i-H$-bond MO is given by the difference between Eq. (20.19) and Eq. (20.7):

$$
\begin{equation*}
E_{T}\left(S i-H, 3 s p^{3}\right)=E\left(S i_{\text {silane }}, 3 s p^{3}\right)-E\left(S i, 3 s p^{3}\right)=-11.63448 \mathrm{eV}-(-10.25487 \mathrm{eV})=-1.37960 \mathrm{eV} \tag{20.20}
\end{equation*}
$$

Consider next the radius of the HO due to the contribution of charge to more than one bond. The energy contribution due to the charge donation at each silicon atom superimposes linearly. In general, the radius $r_{\text {mol } 3 s p^{3}}$ of the $\mathrm{Si} 3 s p^{3} \mathrm{HO}$ of a silicon atom of a given silane molecule is calculated after Eq. (15.32) by considering $\sum E_{T_{\text {mol }}}\left(M O, 3 s p^{3}\right)$, the total energy donation to all bonds with which it participates in bonding. The general equation for the radius is given by:

$$
\begin{equation*}
r_{m o l 3 s p^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0}\left(E_{\text {Coulomb }}\left(S i, 3 s p^{3}\right)+\sum E_{T_{m o l}}\left(M O, 3 s p^{3}\right)\right)}=\frac{e^{2}}{8 \pi \varepsilon_{0}\left(e 10.31324 e V+\sum\left|E_{T_{m o l}}\left(M O, 3 s p^{3}\right)\right|\right)} \tag{20.21}
\end{equation*}
$$

where $E_{\text {Coulomb }}\left(S i, 3 s p^{3}\right)$ is given by Eq. (20.4). The Coulombic energy $E_{\text {Coulomb }}\left(S i, 3 s p^{3}\right)$ of the outer electron of the $S i s p^{3}$ shell considering the charge donation to all participating bonds is given by Eq. (15.14) with Eq. (20.4). The energy $E$ ( $S i, 3 s p^{3}$ ) of the outer electron of the $S i 3 s p^{3}$ shell is given by the sum of $E_{\text {Coulomb }}\left(S i, 3 s p^{3}\right)$ and $E$ (magnetic) (Eq. (20.6)). The final values of the radius of the $S i 3 s p^{3} \mathrm{HO}, r_{3 s p^{3}}, E_{\text {Coulomb }}\left(S i, 3 s p^{3}\right)$, and $E\left(S i_{s i l a n e} 3 s p^{3}\right)$ calculated using $\sum E_{T_{m o l}}\left(M O, 3 s p^{3}\right)$, the total energy
donation to each bond with which an atom participates in bonding are given in Table 20.1. These hybridization parameters are used in Eqs. (15.88-15.117) for the determination of bond angles given in Table 20.7.

Table 20.1. Hybridization parameters of atoms for determination of bond angles with final values of $r_{3 s p^{3}}, E_{\text {Coulomb }}\left(S i, 3 s p^{3}\right)$, and $E\left(S i_{\text {silane }} 3 s p^{3}\right)$ calculated using the appropriate values of $\sum E_{T_{\text {mol }}}\left(M O, 3 s p^{3}\right)\left(E_{T_{m o l}}\left(M O, 3 s p^{3}\right)\right.$ designated as $\left.E_{T}\right)$ for each corresponding terminal bond spanning each angle.

| Atom <br> Hybridization <br> Designation | $E_{T}$ | $E_{T}$ | $E_{T}$ | $E_{T}$ | $E_{T}$ | $r_{3 s p^{3}}$ <br> Final | $E_{\text {Coulomb }}\left(S i, 3 s p^{3}\right)$ <br> $(\mathrm{eV})$ <br> Final | $E\left(S i, 3 s p^{3}\right)$ <br> $(\mathrm{eV})$ <br> Final |

The MO semimajor axis of each functional group of silanes is determined from the force balance equation of the centrifugal, Coulombic, and magnetic forces as given in the Polyatomic Molecular Ions and Molecules section and the More Polyatomic Molecules and Hydrocarbons section. The distance from the origin of the $H_{2}$-type-ellipsoidal-MO to each focus $c^{\prime}$, the internuclear distance $2 c^{\prime}$, and the length of the semiminor axis of the prolate spheroidal $H_{2}$-type MO $b=c$ are solved from the semimajor axis $a$. Then, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117).

The force balance of the centrifugal force equated to the Coulombic and magnetic forces is solved for the length of the semimajor axis. The Coulombic force on the pairing electron of the MO is:

$$
\begin{equation*}
\mathbf{F}_{\text {Coulomb }}=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D \mathbf{i}_{\xi} \tag{20.22}
\end{equation*}
$$

The spin pairing force is

$$
\begin{equation*}
\mathbf{F}_{\text {spin-pairing }}=\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{20.23}
\end{equation*}
$$

The diamagnetic force is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO1 }}=-\frac{n_{e} \hbar^{2}}{4 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{20.24}
\end{equation*}
$$

where $n_{e}$ is the total number of electrons that interact with the binding $\sigma$-MO electron. The diamagnetic force $\mathbf{F}_{\text {diamagneticMOz }}$ on the pairing electron of the $\sigma \mathrm{MO}$ is given by the sum of the contributions over the components of angular momentum:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO2 }}=-\sum_{i, j} \frac{\left|L_{i}\right| \hbar}{Z_{j} 2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{20.25}
\end{equation*}
$$

where $|L|$ is the magnitude of the angular momentum of each atom at a focus that is the source of the diamagnetism at the $\sigma$ MO. The centrifugal force is:

$$
\begin{equation*}
\mathbf{F}_{\text {centrifiugalMO }}=-\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{20.26}
\end{equation*}
$$

The force balance equation for the $\sigma$-MO of the $S i-S i$-bond MO with $n_{e}=3$ and $|L|=4 \sqrt{\frac{3}{4}} \hbar$ corresponding to four electrons of the Si3sp ${ }^{3}$ shell is:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(\frac{3}{2}+\frac{4 \sqrt{\frac{3}{4}}}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \tag{20.27}
\end{equation*}
$$

$$
\begin{equation*}
a=\left(\frac{5}{2}+\frac{4 \sqrt{\frac{3}{4}}}{Z}\right) a_{0} \tag{20.28}
\end{equation*}
$$

With $Z=14$, the semimajor axis of the $\mathrm{Si}-\mathrm{Si}$-bond MO is:

$$
\begin{equation*}
a=2.74744 a_{0} \tag{20.29}
\end{equation*}
$$

The force balance equation for each $\sigma$-MO of the $\mathrm{Si}-H$-bond MO with $n_{e}=2$ and $|L|=4 \sqrt{\frac{3}{4}} \hbar$ corresponding to four electrons of the $S i 3 s p^{3}$ shell is:

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(1+\frac{4 \sqrt{\frac{3}{4}}}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{20.30}\\
& a=\left(2+\frac{4 \sqrt{\frac{3}{4}}}{Z}\right) a_{0} \tag{20.31}
\end{align*}
$$

With $Z=14$, the semimajor axis of the $\mathrm{Si}-H$-bond MO is:
$a=2.24744 a_{0}$
Using the semimajor axis, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in the Organic Molecular Functional Groups and Molecules section. For the $\mathrm{Si}-\mathrm{Si}$ functional group, the $\mathrm{Si3sp}^{3}$ HOs are equivalent; thus, $c_{1}=1$ in both the geometry relationships (Eqs. (15.2-15.5)) and the energy equation (Eq. (15.61)). In order for the bridging MO to intersect the Si3sp ${ }^{3}$ HOs while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical ( OH ) section, for the $\mathrm{Si}-\mathrm{Si}$ functional group, $C_{1}=\frac{0.75}{2}$ in both the geometry relationships (Eqs. (15.2-15.5)) and the energy equation (Eq. (15.61)). This is the same value as $C_{1}$ of the chlorine molecule given in the corresponding section. The hybridization factor gives the parameters $c_{2}$ and $C_{2}$ for both as well. To meet the equipotential condition of the union of the two $S i 3 s p^{3} \mathrm{HOs}, c_{2}$ and $C_{2}$ of Eqs. (15.2-15.5) and Eq. (15.61) for the $\mathrm{Si}-\mathrm{Si}$-bond MO is given by Eq. (15.72) as the ratio of 10.31324 eV , the magnitude of $E_{\text {Coulomb }}\left(S i_{\text {silane }}, 3 s p^{3}\right)$ (Eq. (20.4)), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ (Eq. (1.264)):

$$
\begin{equation*}
C_{2}\left(\text { silaneSi } 3 s p^{3} \mathrm{HO}\right)=c_{2}\left(\text { silaneSi3sp }{ }^{3} \mathrm{HO}\right)=\frac{10.31324 \mathrm{eV}}{13.605804 \mathrm{eV}}=0.75800 \tag{20.33}
\end{equation*}
$$

The energy of the MO is matched to that of the Si3sp ${ }^{3} \mathrm{HO}$ such that $E(A O / H O)$ is $E\left(S i, 3 s p^{3}\right)$ given by Eq. (20.7) and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is two times $E_{T}\left(S i-S i, 3 s p^{3}\right)$ given by Eq. (20.12).

For the $\mathrm{Si}-\mathrm{H}$-bond MO of the $\mathrm{SiH}_{n=1,2,3}$ functional groups, $c_{1}$ is one and $C_{1}=0.75$ based on the orbital composition as in the case of the $C-H$-bond MO. In silanes, the energy of silicon is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{2}$ in Eq. (15.61) is also one, and the energy matching condition is determined by the $C_{2}$ parameter, the hybridization factor for the $\mathrm{Si}-\mathrm{H}$-bond MO given by Eq. (20.33). Since the energy of the MO is matched to that of the $S i 3 s p^{3} \mathrm{HO}, E(A O / H O)$ is $E\left(S i, 3 s p^{3}\right)$ given by Eq. (20.7) and $E_{T}\left(\right.$ atom-atom,msp $\left.{ }^{3} . A O\right)$ is $E_{T}\left(S i-H, 3 s p^{3}\right)$ given by Eq. (20.16). The energy $E_{D}\left(S i H_{n=1,2,3}\right)$ of the functional groups $S i H_{n=1,2,3}$ is given by the integer $n$ times that of $\mathrm{Si}-\mathrm{H}$ :

$$
\begin{equation*}
E_{D}\left(S i H_{n=1,2,3}\right)=n E_{D}(S i H) \tag{20.34}
\end{equation*}
$$

Similarly, for silane, $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ is $E_{T}\left(S i-H, 3 s p^{3}\right)$ given by Eq. (20.20). The energy $E_{D}\left(S i H_{4}\right)$ of $\mathrm{SiH}_{4}$ is given by the integer 4 times that of the $\mathrm{SiH}_{n=4}$ functional group:

$$
\begin{equation*}
E_{D}\left(S i H_{4}\right)=4 E_{D}\left(S i H_{n=4}\right) \tag{20.35}
\end{equation*}
$$

The symbols of the functional groups of silanes are given in Table 20.2. The geometrical (Eqs. (15.1-15.5), (20.1-20.16), (20.29), and (20.32-20.33)), intercept (Eqs. (15.80-15.87) and (20.21)), and energy (Eqs. (15.61), (20.1-20.16), and (20.3320.35)) parameters of silanes are given in Tables 20.3, 20.4, and 20.5, respectively. The total energy of each silane given in Table 20.6 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 20.5 corresponding to functional-group composition of the molecule. $E_{\text {mag }}$ of Table 20.5 is given by Eqs. (15.15) and (20.3). The bond angle parameters of silanes determined using Eqs. (15.88-15.117) are given in Table 20.7. In particular for silanes, the bond angle $\angle H S i H$ is given by Eq. (15.99) wherein $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ is given by Eq. (20.16) in order to match the energy donated from the Si3sp ${ }^{3}$ HO to the $\mathrm{Si}-H$-bond MO due to the energy of silicon being less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). The parameter $c_{2}^{\prime}$ is given by Eq. (15.100) as in the case of a $H-H$ terminal bond of an alkyl or alkenyl group, except that $c_{2}\left(S i 3 s p^{3}\right)$ is given by Eq. (15.63) such that $c_{2}^{\prime}$ is the ratio of $c_{2}$ of Eq. (15.72) for the $H-H$ bond which is one and $c_{2}$ of the silicon of the corresponding $\mathrm{Si}-\mathrm{H}$-bond considering the effect of the formation of the $H-H$ terminal bond:

$$
\begin{equation*}
c_{2}^{\prime}=\frac{1}{c_{2}\left(S i 3 s p^{3}\right)}=\frac{13.605804 \mathrm{eV}}{E_{\text {Coulomb }}\left(S i-H S i 3 s p^{3}\right)} \tag{20.36}
\end{equation*}
$$

The color scale, translucent view of the charge-densities of the series $\mathrm{SiH}_{n=1,2,3,4}$ comprising the concentric shells of the central Si atom of each member with the outer shell joined with one or more hydrogen MOs are shown in Figures 20.1A-D. The
charge-density of disilane is shown in Figure 20.2.

Figure 20.1. (A)-(D) Color scale, translucent view of the charge-densities of the series $\mathrm{SiH}_{n=1,2,3,4}$, showing the orbitals of each member Si atom at their radii, the ellipsoidal surface of each $H_{2}$-type ellipsoidal MO of $H$ that transitions to the outer shell of the Si atom participating in each $\mathrm{Si}-\mathrm{H}$ bond, and the hydrogen nuclei (red, not to scale).

Figure 20.2. Disilane. Color scale, translucent view of the charge-density of $\mathrm{H}_{3} \mathrm{SiSiH}_{3}$ comprising the linear combination of two sets of three $\mathrm{Si}-\mathrm{H}$-bond MOs and a $\mathrm{Si}-\mathrm{Si}$-bond MO with the $\mathrm{Si}_{\text {silane }} 3 s p^{3}$ HOs of the $\mathrm{Si}-\mathrm{Si}$-bond MO shown transparently. The $\mathrm{Si}-\mathrm{Si}$-bond MO comprises a $\mathrm{H}_{2}$-type ellipsoidal MO bridging two $\mathrm{Si}_{\text {silane }} 3 s p^{3}$ HOs. For each $\mathrm{Si}-\mathrm{H}$ and the Si - Si bond, the ellipsoidal surface of the $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the $\mathrm{Si}_{\text {silane }} 3 s p^{3} \mathrm{HO}$, the $\mathrm{Si}_{s_{\text {silane }}} 3 s p^{3} \mathrm{HO}$ shell with radius $0.97295 a_{0}$ (Eq. (20.21)), inner Sils, Si2s, and Si2p shells with radii of Sils = $0.07216 a_{0}$ (Eq. (10.51)), $S i 2 s=0.31274 a_{0}$ (Eq. (10.62)), and Si2p=0.40978 $a_{0}$ (Eq. (10.212)), respectively, and the nuclei (red, not to scale), are shown.

ALKYL SILANES AND DISILANES ( $\left.S i_{m} C_{n} H_{2(m+n)+2}, m, n=1,2,3,4,5 \ldots \infty\right)$
The branched-chain alkyl silanes and disilanes, $\mathrm{Si}_{m} \mathrm{C}_{n} \mathrm{H}_{2(m+n)+2}$, comprise at least a terminal methyl group ( $\mathrm{CH}_{3}$ ) and at least one Si bound by a carbon-silicon single bond comprising a $\mathrm{C}-\mathrm{Si}$ group, and may comprise methylene ( $\mathrm{CH}_{2}$ ), methylyne ( CH ), $\mathrm{C}-\mathrm{C}, \mathrm{SiH}_{n=1,2,3}$, and $\mathrm{Si}-\mathrm{Si}$ functional groups. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straightchain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. These groups in branched-chain alkyl silanes and disilanes are equivalent to those in branched-chain alkanes, and the $\mathrm{SiH}_{n=1,2,3}$ functional groups of alkyl silanes are equivalent to those in silanes $\left(S i_{n} H_{2 n+2}\right)$. The $\mathrm{Si}-\mathrm{Si}$ functional group of alkyl silanes is equivalent to that in silanes; however, in dialkyl silanes, the $S i-S i$ functional group is different due to an energy matching condition with the $C-S i$ bond having a mutual silicon atom.

For the $C-S i$ functional group, hybridization of the $2 s$ and $2 p$ AOs of each $C$ and the $3 s$ and $3 p$ AOs of each $S i$ to form single $2 s p^{3}$ and $3 s p^{3}$ shells, respectively, forms an energy minimum, and the sharing of electrons between the $C 2 s p^{3}$ and Si3sp ${ }^{3}$ HOs to form a MO permits each participating orbital to decrease in radius and energy. In branched-chain alkyl silanes, the energy of silane is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{2}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $C_{2}$ parameter. Then, the $C 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $S i 3 s p^{3} \mathrm{HO}$ has an energy of $E\left(S i, 3 s p^{3}\right)=-10.25487 \mathrm{eV}$ (Eq. (20.7)). To meet the equipotential condition of the union of the $\mathrm{C}-\mathrm{Si} \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $C_{2}$ of Eq. (15.61) for the $C-S i$-bond MO given by Eq. (15.77) is:

$$
\begin{equation*}
C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Si} 3 s p^{3} \mathrm{HO}\right)=\frac{E\left(S i, 3 s p^{3}\right)}{E\left(C, 2 s p^{3}\right)}=\frac{-10.25487 \mathrm{eV}}{-14.63489 \mathrm{eV}}=0.70071 \tag{20.37}
\end{equation*}
$$

For monosilanes, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-S i$-bond MO is -1.20473 eV corresponding to the single-bond contributions of carbon and silicon of -0.72457 eV given by Eq. (14.151) and -0.48015 eV given by Eq. (14.151) with $s=1$ in Eq. (15.18). The energy of the $\mathrm{C}-\mathrm{Si}$-bond MO is the sum of the component energies of the $\mathrm{H}_{2}$-type ellipsoidal MO given in Eq. (15.51) with $E(A O / H O)=E\left(S i, 3 s p^{3}\right)$ given by Eq. (20.7) and $\Delta E_{H_{2} M O}(A O / H O)=E_{T}\left(\right.$ atom -atom, $\left.m s p^{3} . A O\right)$ in order to match the energies of the carbon and silicon HOs.

For the co-bonded $\mathrm{Si}-\mathrm{Si}$ group of the $\mathrm{C}-\mathrm{Si}$ group of disilanes, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -0.96031 eV , two times $E_{T}\left(S i-S i, 3 s p^{3}\right)$ given by Eq. (20.12). Thus, in order to match the energy between these groups, $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)$ of the $\mathrm{C}-\mathrm{Si}$-bond MO is -0.92918 eV corresponding to the single-bond methylene-type contribution of carbon given by Eq. (14.513). As in the case of monosilanes, $E(A O / H O)=E\left(S i, 3 s p^{3}\right)$ given by Eq. (20.7) and $\Delta E_{H_{2} M O}(A O / H O)=E_{T}\left(\right.$ atom -atom, $\left.m s p^{3} . A O\right)$ in order to match the energies of the carbon and silicon HOs.

The symbols of the functional groups of alkyl silanes and disilanes are given in Table 20.8. The geometrical (Eqs. (15.115.5), (20.1-20.16), (20.29), (20.32-20.33) and (20.37)) and intercept (Eqs. (15.80-15.87) and (20.21)) parameters of alkyl silanes and disilanes are given in Tables 20.9 and 20.10, respectively. Since the energy of the Si3sp ${ }^{3} \mathrm{HO}$ is matched to that of the $C 2 s p^{3} \mathrm{HO}$, the radius $r_{\text {mol } 2 s p^{3}}$ of the $S i 3 s p^{3} \mathrm{HO}$ of the silicon atom and the $C 2 s p^{3} \mathrm{HO}$ of the carbon atom of a given $C-S i-$ bond MO is calculated after Eq. (15.32) by considering $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$, the total energy donation to all bonds with which each atom participates in bonding. In the case that the MO does not intercept the Si HO due to the reduction of the radius from the donation of $\mathrm{Si} 3 s p^{3} \mathrm{HO}$ charge to additional MO's, the energy of each MO is energy matched as a linear sum to the Si HO by contacting it through the bisector current of the intersecting MOs as described in the Methane Molecule ( $\mathrm{CH}_{4}$ ) section. The energy (Eqs. (15.61), (20.1-20.16), and (20.33-20.37)) parameters of alkyl silanes and disilanes are given in Table 20.11. The total energy of each alkyl silane and disilane given in Table 20.12 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 20.11 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl silanes and disilanes determined using Eqs. (15.88-15.117) and Eq. (20.36) are given in Table 20.13. The charge-densities of exemplary alkyl silane, dimethylsilane and alkyl disilane, hexamethyldisilane comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 20.3 A and B , respectively.

Figure 20.3. (A) Dimethylsilane and (B) Hexamethyldisilane, color scale, translucent views of the charge-density of each silane showing the orbitals of the Si and C atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 20.13. The bond angle parameters of alkyl silanes and disilanes and experimental values. In the calculation of $\theta_{v}$, the parameters from the preceding angle were

## SILICON OXIDES, SILICIC ACIDS, SILANOLS, SILOXANES AND DISILOXANES

The silicon oxides, silicic acids, silanols, siloxanes, and disiloxanes each comprise at least one $\mathrm{Si}-\mathrm{O}$ group, and this group in disiloxanes is part of the $\mathrm{Si}-\mathrm{O}-\mathrm{Si}$ moiety. Silicic acids may have up to three $\mathrm{Si}-\mathrm{H}$ bonds corresponding to the $\mathrm{SiH}_{n=1,2,3}$ functional groups of alkyl silanes, and silicic acids and silanols further comprise at least one $O H$ group equivalent to that of alcohols. In addition to the $\mathrm{SiH}_{n=1,2,3}$ group of alkyl silanes, silanols, siloxanes, and disiloxanes may comprise the functional groups of organic molecules as well as the $C-S i$ group of alkyl silanes. The alkyl portion of the alkyl silanol, siloxane, or disiloxane may comprise at least one terminal methyl group $\left(\mathrm{CH}_{3}\right)$ the end of each alkyl chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne ( CH ) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $\mathrm{C}-\mathrm{C}$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and tbutyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in silanols, siloxanes, and disiloxanes are equivalent to those in branchedchain alkanes. The alkene groups when present such as the $C=C$ group are equivalent to those of the corresponding alkene. Siloxanes further comprise two types of $C-O$ functional groups, one for methyl or t-butyl groups corresponding to the $C$ and the other for general alkyl groups as given for ethers.

The distinguishing aspect of silicon oxides, silicic acids, silanols, siloxanes, and disiloxane is the nature of the corresponding $\mathrm{Si}-\mathrm{O}$ functional group. In general, the sharing of electrons between a $\mathrm{Si} 3 \mathrm{sp}{ }^{3} \mathrm{HO}$ and an O 2 p AO to form a $\mathrm{Si}-\mathrm{O}$-bond MO permits each participating orbital to decrease in size and energy. Consider the case wherein the Si3sp ${ }^{3} \mathrm{HO}$ donates an excess of $50 \%$ of its electron density to the $\mathrm{Si}-\mathrm{O}$-bond MO to form an energy minimum while further satisfying the potential, kinetic, and orbital energy relationships. By considering this electron redistribution in the molecule comprising a $\mathrm{Si}-\mathrm{O}$ bond as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{S i-O 3 s p^{3}}$ of the $S i 3 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$
\begin{equation*}
r_{S i-O 3 s p^{3}}=\left(\sum_{n=10}^{13}(Z-n)-0.5\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 105.23554 \mathrm{eV})}=\frac{9.5 e^{2}}{8 \pi \varepsilon_{0}(e 105.23554 \mathrm{eV})}=1.22825 a_{0} \tag{20.38}
\end{equation*}
$$

Using Eqs. (15.19) and (20.38), the Coulombic energy $E_{\text {Coulomb }}\left(S i_{S i-O}, 3 s p^{3}\right)$ of the outer electron of the $S i 3 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(S i_{S i-O}, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{S i-O 3 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.22825 a_{0}}=-11.07743 \mathrm{eV} \tag{20.39}
\end{equation*}
$$

During hybridization, the spin-paired $3 s$ electrons are promoted to the $S i 3 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (20.6). Using Eqs. (20.6) and (20.39), the energy $E\left(S i_{S i-O}, 3 s p^{3}\right)$ of the outer electron of the $S i 3 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(S i_{S i-O}, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {silane } 3 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{12}\right)^{3}}=-11.07743 \mathrm{eV}+0.05836 \mathrm{eV}=-11.01906 \mathrm{eV} \tag{20.40}
\end{equation*}
$$

Thus, $E_{T}\left(S i-O, 3 s p^{3}\right)$, the energy change of each $S i 3 s p^{3}$ shell with the formation of the $S i-O$-bond MO is given by the difference between Eq. (20.40) and Eq. (20.7):

$$
\begin{equation*}
E_{T}\left(S i-O, 3 s p^{3}\right)=E\left(S i_{S i-O}, 3 s p^{3}\right)-E\left(S i, 3 s p^{3}\right)=-11.01906 \mathrm{eV}-(-10.25487 \mathrm{eV})=-0.76419 \mathrm{eV} \tag{20.41}
\end{equation*}
$$

Using Eq. (15.28), to meet the energy matching condition in silanols and siloxanes for all $\sigma$ MOs at the Si3sp ${ }^{3} \mathrm{HO}$ and $O 2 p \mathrm{AO}$ of each $\mathrm{Si}-\mathrm{O}$-bond MO as well as with the $C 2 s p^{3} \mathrm{HOs}$ of the molecule, the energy $E\left(S i_{R S i-O R^{\prime}}, 3 s p^{3}\right)$ ( $R, R^{\prime}$ are alkyl or $H$ ) of the outer electron of the $S i 3 s p^{3}$ shell of the silicon atom must be the average of $E\left(S i_{\text {silane }}, 3 s p^{3}\right)$ (Eq. (20.11)) and $E_{T}\left(S i-O, 3 s p^{3}\right)($ Eq. (20.40)).

$$
\begin{equation*}
E\left(S i_{R S i-O R^{\prime}}, 3 s p^{3}\right)=\frac{E\left(S i_{\text {silane }}, 3 s p^{3}\right)+E\left(S i_{S i-O}, 3 s p^{3}\right)}{2}=\frac{(-10.73503 \mathrm{eV})+(-11.01906 \mathrm{eV})}{2}=-10.87705 \mathrm{eV} \tag{20.42}
\end{equation*}
$$

Using Eq. (15.29), $E_{T_{\text {slimono sisloxane }}}\left(S i-O, 3 s p^{3}\right)$, the energy change of each $S i 3 s p^{3}$ shell with the formation of each $R S i-O R^{\prime}$-bond MO, must be the average of $E_{T}\left(S i-S i, 3 s p^{3}\right)$ (Eq. (20.12)) and $E_{T}\left(S i-O, 3 s p^{3}\right)$ (Eq. (20.41)).

$$
\begin{equation*}
E_{T_{\text {Sllanol, ,lilaxane }}}\left(S i-O, 3 s p^{3}\right)=\frac{E_{T}\left(S i-S i, 3 s p^{3}\right)+E_{T}\left(S i-O, 3 s p^{3}\right)}{2}=\frac{(-0.48015 \mathrm{eV})+(-0.76419 \mathrm{eV})}{2}=-0.62217 \mathrm{eV} \tag{20.43}
\end{equation*}
$$

To meet the energy matching condition in silicic acids for all $\sigma$ MOs at the $\operatorname{Si3sp^{3}} \mathrm{HO}$ and O 2 p AO of each $\mathrm{Si}-\mathrm{O}$ bond MO as well as all $H$ AOs, the energy $E\left(S i_{H_{n} S i-(O H)_{4-n}}, 3 s p^{3}\right)$ of the outer electron of the $S i 3 s p^{3}$ shell of the silicon atom must be the average of $E\left(S i_{\text {silane }}, 3 s p^{3}\right)$ (Eq. (20.15)) and $E_{T}\left(S i-O, 3 s p^{3}\right)$ (Eq. (20.40)).

$$
\begin{equation*}
E\left(S i_{H_{n} S i-(O H)_{4-n}}, 3 s p^{3}\right)=\frac{E\left(S i_{\text {silane }}, 3 s p^{3}\right)+E\left(S i_{S i-O}, 3 s p^{3}\right)}{2}=\frac{(-11.37682 \mathrm{eV})+(-11.01906 \mathrm{eV})}{2}=-11.16876 \mathrm{eV} \tag{20.44}
\end{equation*}
$$

Using Eq. (15.29), $E_{T_{\text {silicic acid }}}\left(S i-O, 3 s p^{3}\right)$, the energy change of each $S i 3 s p^{3}$ shell with the formation of each $R S i-O R^{\prime}$-bond MO, must be the average of $E_{T}\left(S i-H, 3 s p^{3}\right)$ (Eq. (20.16)) and $E_{T}\left(S i-O, 3 s p^{3}\right)$ (Eq. (20.41)).

$$
\begin{equation*}
E_{T_{\text {slicica caid }}}\left(S i-O, 3 s p^{3}\right)=\frac{E_{T}\left(S i-H, 3 s p^{3}\right)+E_{T}\left(S i-O, 3 s p^{3}\right)}{2}=\frac{(-1.06358 \mathrm{eV})+(-0.76419 \mathrm{eV})}{2}=-0.91389 \mathrm{eV} \tag{20.45}
\end{equation*}
$$

Using Eqs. (20.22-22.26), the general force balance equation for the $\sigma$-MO of the silicon to oxygen $\mathrm{Si}-\mathrm{O}$-bond MO in terms of $n_{e}$ and $\left|L_{i}\right|$ corresponding to the angular momentum terms of the $3 s p^{3} \mathrm{HO}$ shell is:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(\frac{n_{e}}{2}+\sum_{i} \frac{\left|L_{i}\right|}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \tag{20.46}
\end{equation*}
$$

Having a solution for the semimajor axis $a$ of:

$$
\begin{equation*}
a=\left(1+\frac{n_{e}}{2}+\sum_{i} \frac{\left|L_{i}\right|}{Z}\right) a_{0} \tag{20.47}
\end{equation*}
$$

In terms of the angular momentum $L$, the semimajor axis $a$ is:

$$
\begin{equation*}
a=\left(1+\frac{n_{e}}{2}+\frac{L}{Z}\right) a_{0} \tag{20.48}
\end{equation*}
$$

Using the semimajor axis, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in the Organic Molecular Functional Groups and Molecules section. The semimajor axis $a$ solutions given by Eq. (20.48) of the force balance equation, Eq. (20.46), for the $\sigma$-MO of the $\mathrm{Si}-\mathrm{O}$-bond MO of each functional group of silicon oxide, silicon dioxide, silicic acids, silanols, siloxanes, and disiloxanes are given in Table 20.15 with the force-equation parameters $Z=14, n_{e}$, and $L$ corresponding to the angular momentum of the $\mathrm{Si}_{\mathrm{sip}}{ }^{3} \mathrm{HO}$ shell.

For the $\mathrm{Si}-\mathrm{O}$ functional groups, hybridization of the $3 s$ and $3 p$ AOs of Si to form a single $3 s p^{3}$ shell forms an energy minimum, and the sharing of electrons between the $S i 3 s p^{3} \mathrm{HO}$ and the $O$ AO to form a MO permits each participating orbital to decrease in radius and energy. The $O$ AO has an energy of $E(O)=-13.61805 \mathrm{eV}$, and the Si3sp ${ }^{3}$ HO has an energy of $E\left(S i, 3 s p^{3}\right)=-10.25487 \mathrm{eV}$ (Eq. (20.7)). To meet the equipotential condition of the union of the $\mathrm{Si}-\mathrm{O} \mathrm{H}_{2}$-type-ellipsoidalMO with these orbitals, the corresponding hybridization factors $c_{2}$ and $C_{2}$ of Eq. (15.61) for silicic acids, silanols, siloxanes, and disiloxanes and the hybridization factor $C_{2}$ of silicon oxide and silicon dioxide given by Eq. (15.77) are:

$$
\begin{equation*}
c_{2}\left(O \text { to Si3sp }{ }^{3} \mathrm{HO}\right)=C_{2}(O \text { to Si3sp } \mathrm{HO})=\frac{E\left(S i, 3 s p^{3}\right)}{E(O)}=\frac{-10.25487 \mathrm{eV}}{-13.61805 \mathrm{eV}}=0.75304 \tag{20.49}
\end{equation*}
$$

Each bond of silicon oxide and silicon dioxide is a double bond such that $c_{1}=2$ and $C_{1}=0.75$ in the geometry relationships (Eqs. (15.2-15.5)) and the energy equation (Eq. (15.61)). Each $\mathrm{Si}-\mathrm{O}$ bond in silicic acids, silanols, siloxanes, and disiloxanes is a single bond corresponding to $c_{1}=1$ and $C_{1}=0.5$ as in the case of alkanes (Eq. (14.152)).

Since the energy of the MO is matched to that of the Si3sp ${ }^{3} \mathrm{HO}, E(A O / H O)$ in Eq. (15.61) is $E\left(S i, 3 s p^{3}\right)$ given by Eq. (20.7) and twice this value for double bonds. $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $S i-O$-bond MO of each functional group is determined by energy matching in the molecule while achieving an energy minimum. For silicon oxide and silicon dioxide, $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . A O\right)$ is three and two times -1.37960 eV given by Eq. (20.20), respectively. $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)$ of silicic acids is two times -0.91389 eV given by Eq. (20.45). $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of silanols, siloxanes, and disiloxanes is two times -0.62217 eV given by Eq. (20.43).

The symbols of the functional groups of silicon oxides, silicic acids, silanols, siloxanes, and disiloxanes are given in Table 20.14. The geometrical (Eqs. (15.1-15.5), (20.1-20.21), (20.29), (20.32-20.33), (20.37), and (20.46-20.49)) and intercept (Eqs. (15.80-15.87) and (20.21)) parameters are given in Tables 20.15 and 20.16, respectively. The energy (Eqs. (15.61), (20.120.20), (20.33-20.35), (20.37-45), and (20.49)) parameters are given in Table 20.17. The total energy of each silicon oxide, silicic acid, silanol, siloxane, or disiloxane given in Table 20.18 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 20.17 corresponding to functional-group composition of the molecule. The bond angle parameters determined
using Eqs. (15.88-15.117) are given in Table 20.19. The charge-densities of exemplary siloxane, $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{SiO}\right)_{3}$ and disiloxane, hexamethyldisiloxane comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 20.4A and B, respectively.

Figure 20.4. (A) Color scale, translucent view of the charge-density of $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{SiO}\right)_{3}$ showing the orbitals of the $\mathrm{Si}, \mathrm{O}$, and $C$ atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale). (B) Color scale, translucent view of the charge-density of $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{SiOSi}\left(\mathrm{CH}_{3}\right)_{3}$ showing the orbitals of the $\mathrm{Si}, \mathrm{O}$, and C atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale).

Table 20.14. The symbols of functional groups of silicon oxides, silicic acids, silanols, siloxanes and disiloxanes.

| Functional Group | Group Symbol |
| :---: | :---: |
| SiO bond (silicon oxide) | $\mathrm{Si}-\mathrm{O}$ (i) |
| SiO bond (silicon dioxide) | $\mathrm{Si}-\mathrm{O}$ (ii) |
| SiO bond (silicic acid) | $\mathrm{Si}-\mathrm{O}$ (iii) |
| SiO bond (silanol and siloxane) | $\mathrm{Si}-\mathrm{O}$ (iv) |
| Si -OSi bond (disiloxane) | $\mathrm{Si}-\mathrm{O}$ (v) |
| SiH group of $\mathrm{SiH}_{n=1,2,3}$ | Si-H |
| CSi bond | C-Si (i) |
| OH group | OH |
| $\mathrm{CO}\left(\mathrm{CH}_{3}-\mathrm{O}-\right.$ and $\left.\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}-\mathrm{O}-\right)$ | $C-O$ (i) |
| CO (alkyl) | $C-O$ (ii) |
| $\mathrm{CH}_{3}$ group | $\mathrm{C}-\mathrm{H}\left(\mathrm{CH}_{3}\right)$ |
| $\mathrm{CH}_{2}$ group | $\mathrm{C}-\mathrm{H}\left(\mathrm{CH}_{2}\right)$ |
| CH | C-H |
| $C C$ bond (n-C) | $C-C$ (a) |
| $C C$ bond (iso-C) | $C-C$ (b) |
| $C C$ bond (tert-C) | $C-C$ (c) |
| $C C$ (iso to iso-C) | $C-C$ (d) |
| $C C$ ( $t$ to $t-C$ ) | $C-C$ (e) |
| $\underline{C C}(t$ to iso-C) | $C-C$ (f) |

## SUMMARY TABLES OF SILICON MOLECULES

The bond energies, calculated using closed-form equations having integers and fundamental constants only for classes of molecules whose designation is based on the main functional group, are given in the following tables with the experimental values.

Table 20.20.1. Summary results of silanes.

| Formula | Name | Calculated <br> Total Bond <br> Energy (eV) | Experimental <br> Total Bond <br> Energy (eV) | Relative <br> Error |
| :--- | :--- | :---: | :---: | :---: |
| SiH | silylidyne | 3.07526 | $3.02008[6]$ | -0.01827 |
| $\mathrm{SiH}_{2}$ | silylene | 6.15052 | $6.35523[7]$ | 0.03221 |
| $\mathrm{SiH}_{3}$ | silyl | 9.22578 | $9.36494[7]$ | 0.01486 |
| $\mathrm{SiH}_{4}$ | silane | 13.57257 | $13.34577[6]$ | -0.01699 |
| $\mathrm{Si}_{2} \mathrm{H}_{6}$ | disilane | 21.76713 | $22.05572[7]$ | 0.01308 |
| $\mathrm{Si}_{3} \mathrm{H}_{8}$ | trisilane | 31.23322 | $30.81334[7]$ | -0.01363 |

Table 20.20.2. Summary results of alkyl silanes and disilanes.

| Formula | Name | Calculated <br> Total Bond <br> Energy (eV) | Experimental <br> Total Bond <br> Energy (eV) | Relative <br> Error |
| :--- | :--- | :---: | :---: | :---: |
| $\mathrm{CH}_{6} \mathrm{Si}$ | methylsilane | 25.37882 | $25.99491[9]$ | 0.02370 |
| $\mathrm{C}_{2} \mathrm{H}_{8} \mathrm{Si}$ | dimethylsilane | 38.45660 | $38.64819[9]$ | 0.00496 |
| $\mathrm{C}_{3} \mathrm{H}_{10} \mathrm{Si}$ | trimethylsilane | 51.53438 | $51.33567[9]$ | -0.00387 |
| $\mathrm{C}_{4} \mathrm{H}_{12} \mathrm{Si}$ | tetramethylsilane | 64.61216 | $64.22319[14]$ | -0.00606 |
| $\mathrm{C}_{4} \mathrm{H}_{12} \mathrm{Si}$ | diethylsilane | 62.77200 | $63.37771[15]$ | 0.00956 |
| $\mathrm{C}_{6} \mathrm{H}_{16} \mathrm{Si}$ | triethylsilane | 88.00748 | $87.46141[15]$ | -0.00624 |
| $\mathrm{C}_{8} \mathrm{H}_{20} \mathrm{Si}$ | tetraethylsilane | 113.24296 | $112.06547[15]$ | -0.01051 |
| $\mathrm{CH}_{8} \mathrm{Si}_{2}$ | methyldisilane | 34.56739 | $34.73920[16]$ | 0.00495 |
| $\mathrm{C}_{2} \mathrm{H}_{12} \mathrm{Si}_{2}$ | 1,1-dimethyldisilane | 47.36764 | $47.42283[16]$ | 0.00116 |
| $\mathrm{C}_{2} \mathrm{H}_{10} \mathrm{Si}_{2}$ | 1,2 -dimethyldisilane | 47.36764 | $47.42283[16]$ | 0.00116 |
| $\mathrm{C}_{3} \mathrm{H}_{12} \mathrm{Si}_{2}$ | $1,1,1$-trimethyldisilane | 60.16789 | $60.10646[16]$ | -0.00102 |
| $\mathrm{C}_{3} \mathrm{H}_{12} \mathrm{Si}_{2}$ | $1,1,2$-trimethyldisilane | 60.16789 | $60.10646[16]$ | -0.00102 |
| $\mathrm{C}_{4} \mathrm{H}_{14} \mathrm{Si}_{2}$ | $1,1,1,2$-tetramethyldisilane | 72.96815 | $72.79442[16]$ | -0.00239 |
| $\mathrm{C}_{4} \mathrm{H}_{14} \mathrm{Si}_{2}$ | $1,1,2,2$-tetramethyldisilane | 72.96815 | $72.79442[16]$ | -0.00239 |
| $\mathrm{C}_{5} \mathrm{H}_{16} \mathrm{Si}_{2}$ | $1,1,1,2,2$-pentamethyldisilane | 85.76840 | $85.47805[16]$ | -0.00340 |
| $\mathrm{C}_{6} \mathrm{H}_{18} \mathrm{Si}_{2}$ | hexamethyldisilane | 98.56865 | $98.32646[16]$ | -0.00246 |

Table 20.20.3. Summary results of silicon oxides, silicic acids, silanols, siloxanes, and disiloxanes.

| Formula | Name | Calculated <br> Total Bond <br> Energy (eV) | Experimental Total Bond Energy (eV) | Relative Error |
| :---: | :---: | :---: | :---: | :---: |

# THE NATURE OF THE SEMICONDUCTOR BOND OF SILICON 

## GENERALIZATION OF THE NATURE OF THE SEMICONDUCTOR BOND

Semiconductors are solids that have properties intermediate between insulators and metals. For an insulator to conduct, high energy and power are required to excite electrons into a conducting state in sufficient numbers. Application of high energy to cause electron ionization to the continuum level or to cause electrons to transition to conducing molecular orbitals (MOs) will give rise to conduction when the power is adequate to maintain a high population density of such states. Only high temperatures or extremely high-strength electric fields will provide enough energy and power to achieve an excited state population permissive of conduction. In contrast, metals are highly conductive at essentially any field strength and power. Diamond and alkali metals given in the corresponding sections are representative of insulator and metal classes of solids at opposite extremes of conductivity. It is apparent from the bonding of diamond comprising a network of highly stable MOs that it is an insulator, and the planar free-electron membranes in metals give rise to their high conductivity.

Column IV elements silicon, germanium, and $\alpha$-gray tin all have the diamond structure and are insulators under standard conditions. However, the electrons of these materials can be exited into a conducting excited state with modest amounts of energy compared to a pure insulator. As opposed to the 5.2 eV excitation energy for carbon, silicon, germanium, and $\alpha$-gray tin have excitation energies for conduction of only $1.1 \mathrm{eV}, 0.61 \mathrm{eV}$, and 0.078 eV , respectively. Thus, a semiconductor can carry a current by providing the relatively small amount of energy required to excite electrons to conducting excited states. As in the case of insulators, excitation can occur thermally by a temperature increase. Since the number of excited electrons increases with temperature, a concomitant increase in conductance is observed. This behavior is the opposite of that of metals. Alternatively, the absorption of photons of light causes the electrons in the ground state to be excited to a conducting state that is the basis of conversion of solar power into electricity in solar cells and detection and reception in photodetectors and fiber optic communications, respectively. In certain semiconductors, rather than decay by internal conversion to phonons, the energy of excited-state electrons is emitted as light as the electrons transition from the excited conducting state to the ground state. This photon emission process is the basis of light emitting diodes (LEDs) and semiconductor lasers which have broad application in industry.

In addition to elemental materials such as silicon and germanium, semiconductors may be compound materials such as gallium arsenide and indium phosphide, or alloys such as silicon germanium or aluminum arsenide. Conduction in materials such as silicon and germanium crystals can be enhanced by adding small amounts (e.g. 1-10 parts per million) of dopants such as boron or phosphorus as the crystals are grown. Phosphorous with five valance electrons has a free electron even after contributing four electrons to four single bond-MOs of the diamond structure of silicon. Since this fifth electron can be ionized from a phosphorous atom with only 0.011 eV provided by an applied electric field, phosphorous as an electron donor makes silicon a conductor.

In an opposite manner to that of the free electrons of the dopant carrying electricity, an electron acceptor may also transform silicon to a conductor. Atomic boron has only three valance electrons rather than the four needed to replace a silicon atom in the diamond structure of silicon. Consequently, a neighboring silicon atom has an unpaired electron per boron atom. These electrons can be ionized to carry electricity as well. Alternatively, a valance electron of a silicon atom neighboring a boron atom can be excited to ionize and bind to the boron. The resulting negative boron ion can remain stationary as the corresponding positive center on silicon migrates from atom to atom in response to an applied electric field. This occurs as an electron transfers from a silicon atom with four electrons to one with three to fill the vacant silicon orbital. Concomitantly, the positive center is transferred in the opposite direction. Thus, inter-atomic electron transfer can carry current in a cascade effect as the propagation of a "hole" in the opposite direction as the sequentially transferring electrons.

The ability of the conductivity of semiconductors to transition from that of insulators to that of metals with the application of sufficient excitation energy implies a transition of the excited electrons from covalent to metallic-bond electrons.

The bonding in diamond shown in the Nature of the Molecular Bond of Diamond section is a network of covalent bonds. Semiconductors comprise covalent bonds wherein the electrons are of sufficiently high energy that excitation creates an ion and a free electron. The free electron forms a membrane as in the case of metals given in the Nature of the Metallic Bond of Alkali Metals section. This membrane has the same planar structure throughout the crystal. This feature accounts for the high conductivity of semiconductors when the electrons are excited by the application of external fields or electromagnetic energy that causes ion-pair ( $M^{+}-e^{-}$) formation.

It was demonstrated in the Nature of the Metallic Bond of Alkali Metals section that the solutions of the external point charge at an infinite planar conductor are also those of the metal ions and free electrons of metals based on the uniqueness of solutions of Maxwell's equations and the constraint that the individual electrons in a metal conserve the classical physical laws of the macro-scale conductor. The nature of the metal bond is a lattice of metal ions with field lines that end on the corresponding lattice of electrons comprising two-dimensional charge density $\sigma$ given by Eq. (19.6) where each is equivalent electrostatically to a image point charge at twice the distance from the point charge of $+e$ due to $M^{+}$. Thus, the metallic bond is equivalent to the ionic bond given in the Alkali-Hydride Crystal Structures section with a Madelung constant of one with each negative ion at a position of one half the distance between the corresponding positive ions, but electrostatically equivalent to being positioned at twice this distance, the $M^{+}-M^{+}$-separation distance. Then, the properties of semiconductors can be understood as due to the excitation of a bound electron from a covalent state such as that of the diamond structure to a metallic state such as that of an alkali metal. The equations are the same as those of the corresponding insulators and metals.

## NATURE OF THE INSULATOR-TYPE SEMICONDUCTOR BOND

As given in the Nature of the Solid Molecular Bond of Diamond section, diamond $C-C$ bonds are all equivalent, and each $C-C$ bond can be considered bound to a t-butyl group at the corresponding vertex carbon. Thus, the parameters of the diamond $C$ - $C$ functional group are equivalent to those of the t-butyl $C-C$ group of branched alkanes given in the Branched Alkanes section. Silicon also has the diamond structure. The diamond $S i-S i$ bonds are all equivalent, and each $S i-S i$ bond can be considered bound to three other $\mathrm{Si}-\mathrm{Si}$ bonds at the corresponding vertex silicon. Thus, the parameters of the crystalline silicon $\mathrm{Si}-\mathrm{Si}$ functional group are equivalent to those of the $\mathrm{Si}-\mathrm{Si}$ group of silanes given in the Silanes $\left(\mathrm{Si}_{n} \mathrm{H}_{2 n+2}\right)$ section except for the $E_{T}\left(\right.$ atom-atom, msp $\left.^{3} . A O\right)$ term of Eq. (15.61). Since bonds in pure crystalline silicon are only between Si3sp ${ }^{3}$ HOs having energy less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264) $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=0$. Also, as in the case of the $C-C$ functional group of diamond, the $S i 3 s p^{3}$ HO magnetic energy $E_{\text {mag }}$ is subtracted due to a set of unpaired electrons being created by bond breakage such that $c_{3}$ of Eq. (15.65) is one, and $E_{\operatorname{mag}}$ is given by Eqs. (15.15) and (20.3).

$$
\begin{equation*}
E_{\text {mag }}\left(S i 3 s p^{3}\right)=c_{3} \frac{8 \pi \mu_{0} \mu_{B}^{2}}{r^{3}}=c_{3} \frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(1.31926 a_{0}\right)^{3}}=c_{3} 0.04983 \mathrm{eV} \tag{21.1}
\end{equation*}
$$

The symbols of the functional group of crystalline silicon is given in Table 21.1. The geometrical (Eqs. (15.1-15.5), (20.3-20.7), (20.29), and (20.33)) parameters of crystalline silicon are given in Table 21.2. Using the internuclear distance $2 c^{\prime}$, the lattice parameter $a$ of crystalline silicon is given by Eq. (17.3). The intercept (Eqs. (15.80-15.87), (20.3), and (20.21)) and energy (Eqs. (15.61), (20.3-20.7), and (20.33)) parameters of crystalline silicon are given in Tables 21.2, 21.3, and 21.4, respectively. The total energy of crystalline silicon given in Table 21.5 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 21.4 corresponding to functional-group composition of the solid. The bond angle parameters of crystalline silicon determined using Eqs. (15.88-15.117), (20.4), (20.33), and (21.1) are given in Table 21.6. The diamond structure of silicon in the insulator state is shown in Figure 21.1. The predicted structure matches the experimental images of silicon determined using STM [1] as shown in Figure 21.2.

## NATURE OF THE CONDUCTOR-TYPE SEMICONDUCTOR BOND

With the application of excitation energy equivalent to at least the band gap in the form of photons for example, electrons in silicon transition to conducting states. The nature of these states are equivalent to those of the electrons of metals with the appropriate lattice parameters and boundary conditions of silicon. Since the planar electron membranes are in contact throughout the crystalline matrix, the Maxwellian boundary condition that an equipotential must exist between contacted perfect conductors maintains that all of the planar electrons are at the energy of the highest energy state electron. This condition with the availability of a multitude of states with different ion separation distances and corresponding energies coupled with a near continuum of phonon states and corresponding energies gives rise to a continuum energy band or conduction band in the excitation spectrum. Thus, the conducting state of silicon comprises a background covalent diamond structure with free metaltype electrons and an equal number of silicon cations dispersed in the covalent lattice wherein excitation has occurred. The band gap can be calculated from the difference between the energy of the free electrons at the minimum electron-ion separation distance (the parameter $d$ given in the Nature of the Metallic Bond of Alkali Metals section) and the energy of the covalent-type electrons of the diamond-type bonds given in the Nature of the Insulator-Type Semiconductor Bond section.

The band gap is the lowest energy possible to form free electrons and corresponding $\mathrm{Si}^{+}$ions. Since the gap is the energy difference between the total energy of the free electrons and the MO electrons, a minimum gap corresponds to the lowest energy state of the free electrons. With the ionization of silicon atoms, planar electron membranes form with the corresponding ions at initial positions of the corresponding bond in the silicon lattice. The potential energy between the electrons and ions is a maximum if the electron membrane comprises the superposition of the two electrons ionized from a corresponding $\mathrm{Si}-\mathrm{Si}$ bond, and the orientation of the membrane is the transverse bisector of the former bond axis such that the magnitude of the potential is four times that of a single $\mathrm{Si}^{+}-e^{-}$pair. In this case, the potential is given by two times Eq. (19.21). Furthermore, all of the field lines of the silicon ions end on the intervening electrons. Thus, the repulsion energy between $\mathrm{Si}^{+}$ions is zero such the energy of the ionized state is a minimum. Using the parameters from Tables 21.1 and 21.6, the $\mathrm{Si}^{+}-e^{-}$distance of $c^{\prime}=1.16332 \AA$, and the calculated $S i^{+}$ionic radius of $r_{S_{i}} 3 s p^{3}=1.16360 a_{0}=0.61575 \AA$ (Eq. 20.17), the lattice structure of crystalline silicon in a conducting state is shown in Figure 21.3.

Figure 21.3. (A), (B), and (C) The conducting state of crystalline silicon showing the covalent diamond-structure network of the unit cell with two electrons ionized from a MO shown as a planar two-dimensional membrane of zero thickness that is the perpendicular bisector of the former $\mathrm{Si}-\mathrm{Si}$ bond axis. The corresponding two $\mathrm{Si}^{+}$ions (smaller radii) are centered at the positions of the atoms that contributed the ionized $S i 3 s p^{3}-\mathrm{HO}$ electrons. The electron equipotential energy surface may superimpose with multiple planar electron membranes. The surface charge density of each electron gives rise to an electric field equivalent to that of image point charge for each corresponding positive ion of the lattice.
(A)

(B)

(C)

The optimal $\mathrm{Si}^{+}$ion-electron separation distance parameter $d$ is given by:

$$
\begin{equation*}
d=c^{\prime}=2.19835 a_{0}=1.16332 \times 10^{-10} \mathrm{~m} \tag{21.2}
\end{equation*}
$$

The band gap is given by the difference in the energy of the free electrons at the optimal $\mathrm{Si}^{+}$-electron separation distance parameter $d$ given by Eq. (21.2) and the energy of the electrons in the initial state of the $S i-S i$-bond MO. The total energy of electrons of a covalent $\mathrm{Si}-\mathrm{Si}$-bond MO $E_{T}\left(S i_{S i-S i M O}\right)$ given by Eq. (15.65) and Table 20.4 is:

$$
\begin{equation*}
E_{T}\left(S i_{S i-S i M O}\right)=E_{T}(M O)+\bar{E}_{\text {osc }}-E_{\text {mag }}=-22.81274 \mathrm{eV}+0.04888-0.04983 \mathrm{eV}=-22.81179 \mathrm{eV} \tag{21.3}
\end{equation*}
$$

The minimum energy of a free-conducting electron in silicon for the determination of the band gap $E_{T(\text { band gap })}\left(\right.$ free $e^{-}$in Si$)$ is given by the sum twice the potential energy and the kinetic energy given by Eqs. (19.21) and (19.24), respectively:

$$
\begin{equation*}
E_{T(b a n d ~ g a p)}\left(\text { free } e^{-} \text {in } S i\right)=V+T=\frac{-2 e^{2}}{4 \pi \varepsilon_{0} d}+\frac{4}{3}\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e} d^{2}}\right) \tag{21.4}
\end{equation*}
$$

In addition, the ionization of the MO electrons increases the charge on the two corresponding $S i 3 s p^{3} \mathrm{HO}$ with a corresponding energy decrease, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ given by one half that of Eq. (20.20). With $d$ given by Eq. (21.2), $E_{T(\text { band gap) }}\left(\right.$ free $e^{-}$in $\left.S i\right)$ is:

$$
\begin{align*}
E_{T(\text { band gap })}\left(\text { free e } e^{-} \text {in } \mathrm{Si}\right) & =\left(\begin{array}{l}
\frac{-2 e^{2}}{4 \pi \varepsilon_{0}\left(1.16332 \times 10^{-10} \mathrm{~m}\right)} \\
+\frac{4}{3}\left(\frac{1}{2} \frac{\hbar^{2}}{m_{e}\left(1.16332 \times 10^{-10} \mathrm{~m}\right)^{2}}\right) \\
+E_{T}\left(\text { atom }- \text { atom, } \mathrm{msp}^{3} \cdot \mathrm{AO}\right)
\end{array}\right) \\
& =-24.75614 \mathrm{eV}+3.75374 \mathrm{eV}-\frac{1.37960}{2} \mathrm{eV}  \tag{21.5}\\
& =-21.69220 \mathrm{eV}
\end{align*}
$$

The band gap in silicon $E_{g}$ given by the difference between $E_{T(b a n d ~ g a p)}\left(f r e e ~ e^{-}\right.$in $\left.S i\right)$ (Eq. (21.5)) and $E_{T}\left(S i_{S i-S i M O}\right)$ (Eq. (21.3)) is:

$$
\begin{align*}
E_{g} & =E_{T(\text { band gap })}\left(\text { free } e^{-} \text {in Si }\right)-E_{T}\left(S i_{\text {Si-SiMO }}\right) \\
& =-21.69220 \mathrm{eV}-(-22.81179 \mathrm{eV})  \tag{21.6}\\
& =1.120 \mathrm{eV}
\end{align*}
$$

The experimental band gap for silicon [6] is:

$$
\begin{equation*}
E_{g}=1.12 \mathrm{eV} \tag{21.7}
\end{equation*}
$$

The calculated band gap is in excellent agreement with the experimentally measured value. This result along with the prediction of the correct lattice parameters, cohesive energy, and bond angles given in Tables 21.2, 21.5, and 21.6, respectively, confirms that conductivity in silicon is due the creation of discrete ions, $\mathrm{Si}^{+}$and $e^{-}$, with the excitation of electrons from covalent bonds. The current carriers are free metal-type electrons that exist as planar membranes with current propagation along these structures shown in Figure 21.3. Since the conducting electrons are equivalent to those of metals, the resulting kinetic energy distribution over the population of electrons can be modeled using the statistics of electrons in metals, Fermi Dirac statistics given in the Fermi-Dirac section and the Physical Implications of Free Electrons in Metals section.

## BORON MOLECULAR FUNCTIONAL GROUPS AND MOLECULES

## GENERAL CONSIDERATIONS OF THE BORON MOLECULAR BOND

Boron molecules comprising an arbitrary number of atoms can be solved using similar principles and procedures as those used to solve organic molecules of arbitrary length and complexity. Boron molecules can be considered to be comprised of functional groups such as $B-B, B-C, B-H, B-O, B-N, B-X$ ( $X$ is a halogen atom), and the alkyl functional groups of organic molecules. The solutions of these functional groups or any others corresponding to the particular boron molecule can be conveniently obtained by using generalized forms of the force balance equation given in the Force Balance of the $\sigma$ MO of the Carbon Nitride Radical section for molecules comprised of boron and hydrogen only and the geometrical and energy equations given in the Derivation of the General Geometrical and Energy Equations of Organic Chemistry section for boron molecules further comprised of heteroatoms such as carbon. The appropriate functional groups with their geometrical parameters and energies can be added as a linear sum to give the solution of any molecule containing boron.

## BORANES ( $B_{x} H_{y}$ )

As in the case of carbon, silicon, and aluminum, the bonding in the boron atom involves four $s p^{3}$ hybridized orbitals formed from the $2 p$ and $2 s$ electrons of the outer shells except that only three HOs are filled. Bonds form between the $B 2 s p^{3}$ HOs of two boron atoms and between a $B 2 s p^{3} \mathrm{HO}$ and a $H 1 s \mathrm{AO}$ to yield boranes. The geometrical parameters of each $B-H$ and $B-B$ functional group is solved from the force balance equation of the electrons of the corresponding $\sigma-\mathrm{MO}$ and the relationships between the prolate spheroidal axes. Then, the sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $B 2 s p^{3}$ shell as in the case of the corresponding carbon molecules. As in the case of ethane ( $C-C$ functional group given in the Ethane Molecule section) and silane ( $\mathrm{Si}-\mathrm{Si}$ functional group given in the Silanes section), the energy of the $B-B$ functional group is determined for the effect of the donation of $25 \%$ electron density from each participating $B 2 s p^{3} \mathrm{HO}$ to the $B-B$-bond MO.

The energy of boron is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). A minimum energy is achieved while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical $(\mathrm{OH})$ section with the donation of $25 \%$ electron density from each participating $B 2 s p^{3} \mathrm{HO}$ to each $B-H$ and $B-B$-bond MO. As in the case of acetylene given in the Acetylene Molecule section, the energies of the $B-H$ and $B-B$ functional groups are determined for the effect of the charge donation.

The $2 s p^{3}$ hybridized orbital arrangement is:

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the four electrons. The sum $E_{T}\left(B, 2 s p^{3}\right)$ of experimental energies [1] of $B, B^{+}$, and $B^{2+}$ is:

$$
\begin{equation*}
E_{T}\left(B, 2 s p^{3}\right)=37.93064 \mathrm{eV}+25.1548 \mathrm{eV}+8.29802 \mathrm{eV}=71.38346 \mathrm{eV} \tag{22.2}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{2 s p^{3}}$ of the $B 2 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{2 s p^{3}}=\sum_{n=2}^{4} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 71.38346 \mathrm{eV})}=\frac{6 e^{2}}{8 \pi \varepsilon_{0}(e 71.38346 \mathrm{eV})}=1.14361 a_{0} \tag{22.3}
\end{equation*}
$$

where $Z=5$ for boron. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(B, 2 s p^{3}\right)$ of the outer electron of the $B 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(B, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{2 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.14361 a_{0}}=-11.89724 \mathrm{eV} \tag{22.4}
\end{equation*}
$$

During hybridization, one of the spin-paired $2 s$ electrons is promoted to the $B 2 s p^{3}$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (15.15) at the initial radius of the $2 s$ electrons. From Eq. (10.62) with $Z=5$, the radius $r_{3}$ of $B 2 s$ shell is

$$
\begin{equation*}
r_{3}=1.07930 a_{0} \tag{22.5}
\end{equation*}
$$

Using Eqs. (15.15) and (22.5), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(1.07930 a_{0}\right)^{3}}=0.09100 \mathrm{eV} \tag{22.6}
\end{equation*}
$$

Using Eqs. (24.4) and (22.6), the energy $E\left(B, 2 s p^{3}\right)$ of the outer electron of the $B 2 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(B, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-11.89724 \mathrm{eV}+0.09100 \mathrm{eV}=-11.80624 \mathrm{eV} \tag{22.7}
\end{equation*}
$$

Next, consider the formation of the $B-H$ and $B-B$-bond MOs of boranes wherein each boron atom has a $B 2 s p^{3}$ electron with an energy given by Eq. (22.7). The total energy of the state of each boron atom is given by the sum over the three electrons. The sum $E_{T}\left(B_{\text {borane }}, 2 s p^{3}\right)$ of energies of $B 2 s p^{3}$ (Eq. (22.7)), $B^{+}$, and $B^{2+}$ is:

$$
\begin{align*}
E_{T}\left(B_{\text {borane }}, 2 s p^{3}\right) & =-\left(37.93064 \mathrm{eV}+25.1548 \mathrm{eV}+E\left(B, 2 s p^{3}\right)\right)  \tag{22.8}\\
& =-(37.93064 \mathrm{eV}+25.1548 \mathrm{eV}+11.80624 \mathrm{eV})=-74.89168 \mathrm{eV}
\end{align*}
$$

where $E\left(B, 2 s p^{3}\right)$ is the sum of the energy of $B,-8.29802 \mathrm{eV}$, and the hybridization energy.
Each $C$ - $H$-bond MO forms with the sharing of electrons between each $B 2 s p^{3} \mathrm{HO}$ and each $H 1 s \mathrm{AO}$. As in the case of $C-H$, the $H_{2}$-type ellipsoidal MO comprises $75 \%$ of the $B-H$-bond MO according to Eq. (13.429) and Eq. (13.59). Similarly to the case of $C-C$, the $B-B \mathrm{H}_{2}$-type ellipsoidal MO comprises $50 \%$ contribution from the participating $B 2 s p^{3}$ HOs according to Eq. (14.152). The sharing of electrons between a $B 2 s p^{3} \mathrm{HO}$ and one or more $H 1 s$ AOs to form $B-H$-bond MOs or between two $B 2 s p^{3}$ HOs to form a $B-B$-bond MO permits each participating orbital to decrease in size and energy. As shown below, the boron HOs have spin and orbital angular momentum terms in the force balance which determines the geometrical parameters of each $\sigma$ MO. The angular momentum term requires that each $\sigma$ MO be treated independently in terms of the charge donation. In order to further satisfy the potential, kinetic, and orbital energy relationships, each $B 2 s p^{3} \mathrm{HO}$ donates an excess of $25 \%$ of its electron density to the $B-H$ or $B-B$-bond MO to form an energy minimum. By considering this electron redistribution in the borane molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{\text {borane } 2 s p^{3}}$ of the $B 2 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$
\begin{equation*}
r_{\text {borane2sp }}=\left(\sum_{n=2}^{4}(Z-n)-0.25\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 74.89168 \mathrm{eV})}=\frac{5.75 e^{2}}{8 \pi \varepsilon_{0}(e 74.89168 \mathrm{eV})}=1.04462 a_{0} \tag{22.9}
\end{equation*}
$$

Using Eqs. (15.19) and (22.9), the Coulombic energy $E_{\text {Coulomb }}\left(B_{\text {borane }}, 2 s p^{3}\right)$ of the outer electron of the $B 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(B_{\text {borane }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {borane } 2 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.04462 a_{0}}=-13.02464 \mathrm{eV} \tag{22.10}
\end{equation*}
$$

During hybridization, one of the spin-paired $2 s$ electrons are promoted to the $B 2 s p^{3}$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (22.6). Using Eqs. (22.6) and (22.10), the energy $E\left(B_{\text {borane }}, 2 s p^{3}\right)$ of the outer electron of the $B 2 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(B_{\text {borane }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {borane } 2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-13.02464 \mathrm{eV}+0.09100 \mathrm{eV}=-12.93364 \mathrm{eV} \tag{22.11}
\end{equation*}
$$

Thus, $E_{T}\left(B-H, 2 s p^{3}\right)$ and $E_{T}\left(B-B, 2 s p^{3}\right)$, the energy change of each $B 2 s p^{3}$ shell with the formation of the $B-H$ and $B-B$-bond MO, respectively, is given by the difference between Eq. (22.11) and Eq. (22.7):

$$
\begin{align*}
E_{T}\left(B-H, 2 s p^{3}\right) & =E_{T}\left(B-B, 2 s p^{3}\right)=E\left(B_{b o r a n e}, 2 s p^{3}\right)-E\left(B, 2 s p^{3}\right)  \tag{22.12}\\
& =-12.93364 \mathrm{eV}-(-11.80624 \mathrm{eV})=-1.12740 \mathrm{eV}
\end{align*}
$$

Next, consider the case that each $B 2 s p^{3} \mathrm{HO}$ donates an excess of $50 \%$ of its electron density to the $\sigma \mathrm{MO}$ to form an energy minimum. By considering this electron redistribution in the borane molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{\text {borane } s s p^{3}}$ of the $B 2 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$
\begin{equation*}
r_{\text {borane } 2 s p^{3}}=\left(\sum_{n=2}^{4}(Z-n)-0.5\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 74.89168 \mathrm{eV})}=\frac{5.5 e^{2}}{8 \pi \varepsilon_{0}(e 74.89168 \mathrm{eV})}=0.99920 a_{0} \tag{22.13}
\end{equation*}
$$

Using Eqs. (15.19) and (22.13), the Coulombic energy $E_{\text {Coulomb }}\left(B_{\text {borane }}, 2 s p^{3}\right)$ of the outer electron of the $B 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(B_{\text {borane }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {borane2sp }}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.99920 a_{0}}=-13.61667 \mathrm{eV} \tag{22.14}
\end{equation*}
$$

During hybridization, one of the spin-paired $2 s$ electrons is promoted to the $B 2 s p^{3}$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (22.6). Using Eqs. (22.6) and (22.14), the energy $E\left(B_{b o r a n e}, 2 s p^{3}\right)$ of the outer electron of the $B 2 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(B_{\text {borane }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {borane } 2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-13.61667 \mathrm{eV}+0.09100 \mathrm{eV}=-13.52567 \mathrm{eV} \tag{22.15}
\end{equation*}
$$

Thus, $E_{T}\left(B\right.$-atom, $\left.2 s p^{3}\right)$, the energy change of each $B 2 s p^{3}$ shell with the formation of the $B$-atom-bond MO is given by the difference between Eq. (22.15) and Eq. (22.7):

$$
\begin{equation*}
E_{T}\left(B-\text { atom, } 2 s p^{3}\right)=E\left(B_{\text {borane }}, 2 s p^{3}\right)-E\left(B, 2 s p^{3}\right)=-13.52567 \mathrm{eV}-(-11.80624 \mathrm{eV})=-1.71943 \mathrm{eV} \tag{22.16}
\end{equation*}
$$

Consider next the radius of the HO due to the contribution of charge to more than one bond. The energy contribution due to the charge donation at each boron atom superimposes linearly. In general, the radius $r_{\text {mol } 2 s p^{3}}$ of the $B 2 s p^{3} \mathrm{HO}$ of a boron atom of a given borane molecule is calculated after Eq. (15.32) by considering $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$, the total energy donation to all bonds with which it participates in bonding. The general equation for the radius is given by:

$$
\begin{equation*}
r_{m o l 3 s p^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0}\left(E_{\text {Coulomb }}\left(B, 2 s p^{3}\right)+\sum E_{T_{\text {mol }}}\left(M O, 2 s p^{3}\right)\right)}=\frac{e^{2}}{8 \pi \varepsilon_{0}\left(e 11.89724 \mathrm{eV}+\sum\left|E_{T_{\text {mol }}}\left(M O, 2 s p^{3}\right)\right|\right)} \tag{22.17}
\end{equation*}
$$

where $E_{\text {Coulomb }}\left(B, 2 s p^{3}\right)$ is given by Eq. (22.4). The Coulombic energy $E_{\text {Coulomb }}\left(B, 2 s p^{3}\right)$ of the outer electron of the $B 2 s p^{3}$ shell considering the charge donation to all participating bonds is given by Eq. (15.14) with Eq. (22.4). The energy $E\left(B, 2 s p^{3}\right)$ of the outer electron of the $B 2 s p^{3}$ shell is given by the sum of $E_{\text {Coulomb }}\left(B, 2 s p^{3}\right)$ and $E$ (magnetic) (Eq. (22.6)). The final values of the radius of the $B 2 s p^{3} \mathrm{HO}, r_{2 s p^{3}}, E_{\text {Coulomb }}\left(B, 2 s p^{3}\right)$, and $E\left(B_{\text {borane }} 2 s p^{3}\right)$ calculated using $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$, the total energy donation to each bond with which an atom participates in bonding are given in Table 22.1. These hybridization parameters are used in Eqs. $(15.88-15.117)$ for the determination of bond angles given in Table 22.7.

Table 22.1. Atom hybridization designation (\# first column) and hybridization parameters of atoms for determination of bond angles with final values of $r_{2 s p^{3}}$, $E_{\text {Coulomb }}\left(B, 2 s p^{3}\right)$ (designated as $\left.E_{\text {Coulomb }}\right)$, and $E\left(B_{\text {borane }} 2 s p^{3}\right)$ (designated as $E$ ) calculated using the appropriate values of $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$ (designated as $E_{T}$ ) for each corresponding terminal bond spanning each angle.

The MO semimajor axes of the $B-H$ and $B-B$ functional groups of boranes are determined from the force balance equation of the centrifugal, Coulombic, and magnetic forces as given in the Polyatomic Molecular Ions and Molecules section and the More Polyatomic Molecules and Hydrocarbons section. In each case, the distance from the origin of the $H_{2}$-type-ellipsoidal-MO to each focus $c^{\prime}$, the internuclear distance $2 c^{\prime}$, and the length of the semiminor axis of the prolate spheroidal
$H_{2}$-type MO $b=c$ are solved from the semimajor axis $a$. Then, the geometric and energy parameters of each MO are calculated using Eqs. (15.1-15.117).

The force balance of the centrifugal force equated to the Coulombic and magnetic forces is solved for the length of the semimajor axis. The Coulombic force on the pairing electron of the MO is:

$$
\begin{equation*}
\mathbf{F}_{\text {Coulomb }}=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D \mathbf{i}_{\xi} \tag{22.18}
\end{equation*}
$$

The spin-pairing force is:

$$
\begin{equation*}
\mathbf{F}_{\text {spin-pairing }}=\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{22.19}
\end{equation*}
$$

The diamagnetic force is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO1 }}=-\frac{n_{e} \hbar^{2}}{4 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{22.20}
\end{equation*}
$$

where $n_{e}$ is the total number of electrons that interact with the binding $\sigma-\mathrm{MO}$ electron. The diamagnetic force $\mathbf{F}_{\text {diamagneticMO2 }}$ on the pairing electron of the $\sigma \mathrm{MO}$ is given by the sum of the contributions over the components of angular momentum:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO2 }}=-\sum_{i, j} \frac{\left|L_{i}\right| \hbar}{Z_{j} 2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{22.21}
\end{equation*}
$$

where $|L|$ is the magnitude of the angular momentum of each atom at a focus that is the source of the diamagnetism at the $\sigma$ MO. The centrifugal force is:

$$
\begin{equation*}
\mathbf{F}_{\text {centrifugalMO }}=-\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{22.22}
\end{equation*}
$$

The force balance equation for the $\sigma-\mathrm{MO}$ of the two-center $B-H$-bond MO is the given by centrifugal force given by Eq. (22.22) equated to the sum of the Coulombic (Eq. (22.18)), spin-pairing (Eq. (22.19)), and $\mathbf{F}_{\text {diamagneticмо2 }}$ (Eq. (22.21)) with $|L|=4 \sqrt{\frac{3}{4}} \hbar$ corresponding to the four $B 2 s p^{3}$ HOs:
$\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\frac{4 \sqrt{\frac{3}{4}}}{Z} \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D$
$a=\left(1+\frac{4 \sqrt{\frac{3}{4}}}{Z}\right) a_{0}$
With $Z=5$, the semimajor axis of the $B-H$-bond MO is:
$a=1.69282 a_{0}$
The force balance equation for each $\sigma$-MO of the $B-B$-bond MO with $n_{e}=2$ and $|L|=3 \sqrt{\frac{3}{4}} \hbar$ corresponding to three electrons of the $B 2 s p^{3}$ shell is:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(1+\frac{3 \sqrt{\frac{3}{4}}}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \tag{22.26}
\end{equation*}
$$

$a=\left(2+\frac{3 \sqrt{\frac{3}{4}}}{Z}\right) a_{0}$
With $Z=5$, the semimajor axis of the $B-B$-bond MO is:
$a=2.51962 a_{0}$
Using the semimajor axis, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.127) in the same manner as the organic functional groups given in the Organic Molecular Functional Groups and Molecules section. For the $B-H$ functional group, $c_{1}$ is one and $C_{1}=0.75$ based on the MO orbital composition as in the case of the $C-H$-bond MO. In boranes, the energy of boron is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, the energy matching condition is determined by the $c_{2}$ and $C_{2}$ parameters in Eqs. (15.51) and (15.61). Then, the hybridization factor for the $B-H$-bond MO given by the ratio of 11.89724 eV , the magnitude of $E_{\text {Coulomb }}\left(B_{\text {borane }}, 2 s p^{3}\right)$ (Eq. (22.4)), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ (Eq. (1.264)):

$$
\begin{equation*}
c_{2}=C_{2}\left(\text { borane } 2 s p^{3} \mathrm{HO}\right)=\frac{11.89724 \mathrm{eV}}{13.605804 \mathrm{eV}}=0.87442 \tag{22.29}
\end{equation*}
$$

Since the energy of the MO is matched to that of the $B 2 s p^{3} \mathrm{HO}, E(A O / H O)$ in Eqs. (15.51) and (15.61) is $E\left(B, 2 s p^{3}\right)$ given by Eq. (22.7), and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is one half of -1.12740 eV corresponding to the independent single-bond charge contribution (Eq. (22.12)) of one center.

For the $B-B$ functional group, $c_{1}$ is one and $C_{1}=0.5$ based on the MO orbital composition as in the case of the $C-C-$ bond MO. The energy matching condition is determined by the $c_{2}$ and $C_{2}$ parameters in Eqs. (15.51) and (15.61), and the hybridization factor for the $B-B$-bond MO given is by Eq. (22.29). Since the energy of the MO is matched to that of the $B 2 s p^{3}$ $\mathrm{HO}, E(A O / H O)$ in Eqs. (15.51) and (15.61) is $E\left(B, 2 s p^{3}\right)$ given by Eq. (22.7), and $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ is two times 1.12740 eV corresponding to the independent single-bond charge contributions (Eq. (22.12)) from each of the two B2sp ${ }^{3}$ HOs.

## BRIDGING BONDS OF BORANES ( $B-H-B$ AND $B-B-B$ )

As in the case of the $A l 3 s p^{3}$ HOs given in the Organoaluminum Hydrides ( $A l-H-A l$ and $A l-C-A l$ ) section, the $B 2 s p^{3}$ HOs comprise four orbitals containing three electrons as given by Eq. (23.1) that can form three-center as well as two-center bonds. The designation for a three-center bond involving two $B 2 s p^{3} \mathrm{HOs}$ and a $H 1 s \mathrm{AO}$ is $B-H-B$, and the designation for a three-center bond involving three $B 2 s p^{3}$ HOs is $B-B-B$.

The parameters of the force balance equation for the $\sigma-\mathrm{MO}$ of the $B-H-B$-bond MO are $n_{e}=2$ and $|L|=0$ due to the cancellation of the angular momentum between borons:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \tag{22.30}
\end{equation*}
$$

From Eq. (22.30), the semimajor axis of the $B-H-B$-bond MO is

$$
\begin{equation*}
a=2 a_{0} \tag{22.31}
\end{equation*}
$$

The parameters in Eqs. (15.51) and (15.61) are the same as those of the $B-H-B$ functional group except that $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . A O\right)$ is two times -1.12740 eV corresponding to the independent single-bond charge contributions (Eq. (22.12)) from each of the two $B 2 s p^{3}$ HOs.

The force balance equation and the semimajor axis for the $\sigma-\mathrm{MO}$ of the $B-B-B$-bond MO are the same as those of the $B-B$-bond MO given by Eqs. (22.30) and (22.31), respectively. The parameters in Eqs. (15.51) and (15.61) are the same as those of the $B-B$ functional group except that $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is three times -1.12740 eV corresponding to the independent single-bond charge contributions (Eq. (22.12)) from each of the three $B 2 s p^{3}$ HOs.

The $H_{2}$-type ellipsoidal MOs of the $B-H-B$ three-center bond intersect and form a continuous single surface. However, in the case of the $B-B-B$-bond MO the current of each $B-B$ MO forms a bisector current described in the Methane Molecule $\left(\mathrm{CH}_{4}\right)$ section that is continuous with the center $B 2 s p^{3}$-HO shell (Eqs. (15.36-15.44)). Based on symmetry, the polar angle $\phi$ at which the $B-H-B \quad H_{2}$-type ellipsoidal MOs intersect is given by the bisector of the external angle between the $B-H$ bonds:

$$
\begin{equation*}
\phi=\frac{360^{\circ}-\theta_{\angle B H B}}{2}=\frac{360^{\circ}-85.4^{\circ}}{2}=137.3^{\circ} \tag{22.32}
\end{equation*}
$$

where [2]

$$
\begin{equation*}
\theta_{\angle B H B}=85.4^{\circ} \tag{22.33}
\end{equation*}
$$

The polar radius $r_{i}$ at this angle is given by Eqs. (13.84-13.85).

$$
\begin{equation*}
r_{i}=\left(a-c^{\prime}\right) \frac{1+\frac{c^{\prime}}{a}}{1+\frac{c^{\prime}}{a} \cos \phi^{\prime}} \tag{22.34}
\end{equation*}
$$

Substitution of the parameters of Table 22.2 into Eq. (22.34) gives:

$$
\begin{equation*}
r_{i}=2.26561 a_{0}=1.19891 \times 10^{-10} \mathrm{~m} \tag{22.35}
\end{equation*}
$$

The polar angle $\phi$ at which the $B-B-B \quad H_{2}$-type ellipsoidal MOs intersect is given by the bisector of the external angle between the $B-B$ bonds:

$$
\begin{equation*}
\phi=\frac{360^{\circ}-\theta_{\angle B B B}}{2}=\frac{360^{\circ}-58.9^{\circ}}{2}=150.6^{\circ} \tag{22.36}
\end{equation*}
$$

where [3]

$$
\begin{equation*}
\theta_{\angle B H B}=58.9^{\circ} \tag{22.37}
\end{equation*}
$$

The polar radius $r_{i}$ at this angle is given by Eqs. (13.84-13.85):

$$
\begin{equation*}
r_{i}=\left(a-c^{\prime}\right) \frac{1+\frac{c^{\prime}}{a}}{1+\frac{c^{\prime}}{a} \cos \phi^{\prime}} \tag{22.38}
\end{equation*}
$$

Substitution of the parameters of Table 22.2 into Eq. (22.38) gives:

$$
\begin{equation*}
r_{i}=3.32895 a_{0}=1.76160 \times 10^{-10} \mathrm{~m} \tag{22.39}
\end{equation*}
$$

The symbols of the functional groups of boranes are given in Table 22.2. The geometrical (Eqs. (15.1-15.5) and (22.23$22.39)$ ), intercept (Eqs. (15.80-15.87) and (22.17)), and energy (Eq. (15.61), (22.4), (22.7), (22.12), and (22.29)) parameters of boranes are given in Tables 22.3, 22.4, and 22.5, respectively. In the case that the MO does not intercept the $B \mathrm{HO}$ due to the reduction of the radius from the donation of $B s p^{3} \mathrm{HO}$ charge to additional MOs, the energy of each MO is energy matched as a linear sum to the $B \mathrm{HO}$ by contacting it through the bisector current of the intersecting MOs as described in the Methane Molecule $\left(\mathrm{CH}_{4}\right)$ section. The total energy of each borane given in Table 22.6 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 22.5 corresponding to functional-group composition of the molecule. $E_{\text {mag }}$ of Table 22.5 is given by Eqs. (15.15) and (22.3). The bond angle parameters of boranes determined using Eqs. (15.88-15.117) and (20.36) with $B 2 s p^{3}$ replacing $S i 3 s p^{3}$ are given in Table 22.7. The charge-density in diborane is shown in Figure 22.1.

Figure 22.1. Diborane. Color scale, opaque view of the charge-density of $B_{2} H_{6}$ comprising the linear combination of two sets of two $B-H$-bond MOs and two $B-H-B$-bond MOs. For each $B-H$ and $B-H-B$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO transitions to the $B 2 s p^{3} \mathrm{HO}$ shell with radius $0.89047 a_{0}$ (Eq. (22.17)). The inner $B 1 s$ radius is $0.20670 a_{0}$ (Eq. (10.51)).

Table 22.2. The symbols of the functional groups of boranes.

| Functional Group | Group Symbol |

## ALKYL BORANES ( $R_{x} B_{y} H_{z} ; R=$ alkyl $)$

The alkyl boranes may comprise at least a terminal methyl group $\left(\mathrm{CH}_{3}\right)$ and at least one $B$ bound by a carbon-boron single bond comprising a $\mathrm{C}-\mathrm{B}$ group, and may comprise methylene ( $\mathrm{CH}_{2}$ ), methylyne ( CH ), $\mathrm{C}-\mathrm{C}, \mathrm{B}-\mathrm{H}, \mathrm{B}-\mathrm{B}, \mathrm{B}-\mathrm{H}-\mathrm{B}$, and $B-B-B$ functional groups. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. Additional groups include aromatics such as phenyl. These groups in alkyl boranes are equivalent to those in branched-chain alkanes and aromatics, and the $B-H, B-B, B-H-B$, and $B-B-B$ functional groups of alkyl boranes are equivalent to those in boranes.

For the $C-B$ functional group, hybridization of the $2 s$ and $2 p$ AOs of each $C$ and $B$ to form single $2 s p^{3}$ shells forms an energy minimum, and the sharing of electrons between the $C 2 s p^{3}$ and $B 2 s p^{3}$ HOs to form a MO permits each participating orbital to decrease in radius and energy. In alkyl boranes, the energy of boron is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{1}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $c_{2}$ and $C_{2}$ parameters. Then, the $C 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $B 2 s p^{3}$ HOs have an energy of $E\left(B, 2 s p^{3}\right)=-11.80624 \mathrm{eV}$ (Eq. (22.7)). To meet the equipotential condition of the union of the $C-B$ $H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factors $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $C-B$-bond MO given by Eq. (15.77) is:

$$
\begin{equation*}
c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{B} 2 s p^{3} \mathrm{HO}\right)=C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{B} 2 s p^{3} \mathrm{HO}\right)=\frac{E\left(B, 2 s p^{3}\right)}{E\left(C, 2 s p^{3}\right)}=\frac{-11.80624 \mathrm{eV}}{-14.63489 \mathrm{eV}}=0.80672 \tag{22.40}
\end{equation*}
$$

$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-B$-bond MO is -1.44915 eV corresponding to the single-bond contributions of carbon and boron of -0.72457 eV given by Eq. (14.151). The energy of the $C-B$-bond MO is the sum of the component energies of the $H_{2}$-type ellipsoidal MO given in Eq. (15.51) with $E(A O / H O)=E\left(B, 2 s p^{3}\right)$ given by Eq. (22.7) and $\Delta E_{H_{2} M O}(A O / H O)=E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ in order to match the energies of the carbon and boron HOs.

Consider next the radius of the HO due to the contribution of charge to more than one bond. The energy contribution due to the charge donation at each boron atom and carbon atom superimposes linearly. In general, since the energy of the $B 2 s p^{3}$ HO is matched to that of the $C 2 s p^{3} \mathrm{HO}$, the radius $r_{\text {mol2sp3 }}$ of the $B 2 s p^{3} \mathrm{HO}$ of a boron atom and the $C 2 s p^{3} \mathrm{HO}$ of a carbon atom of a given alkyl borane molecule is calculated after Eq. (15.32) by considering $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$, the total energy donation to all bonds with which it participates in bonding. The Coulombic energy $E_{\text {Coulomb }}\left(\right.$ atom, $\left.2 s p^{3}\right)$ of the outer electron of the atom $2 s p^{3}$ shell considering the charge donation to all participating bonds is given by Eq. (15.14). The hybridization parameters used in Eqs. (15.88-15.117) for the determination of bond angles of alkyl boranes are given in Table 22.8.

Table 22.8. Atom hybridization designation (\# first column) and hybridization parameters of atoms for determination of bond angles with final values of $r_{2 s p^{3}}, E_{\text {Coulomb }}\left(\right.$ atom, $\left.2 s p^{3}\right)\left(\right.$ designated as $\left.E_{\text {Coulomb }}\right)$, and $E_{\text {Coulomb }}\left(\right.$ atom $\left._{\text {alkylborane }} 2 s p^{3}\right)$ (designated as $E)$ calculated using the appropriate values of $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$ (designated as $E_{T}$ ) for each corresponding terminal bond spanning each angle.

The symbols of the functional groups of alkyl boranes are given in Table 22.9. The geometrical (Eqs. (15.1-15.5) and (22.23-22.40)), intercept (Eqs. (15.32) and (15.80-15.87)), and energy (Eq. (15.61), (22.4), (22.7), (22.12), (22.29), and (22.40)) parameters of alkyl boranes are given in Tables 22.10, 22.11, and 22.12, respectively. In the case that the MO does not intercept the $B \mathrm{HO}$ due to the reduction of the radius from the donation of $B 2 s p^{3} \mathrm{HO}$ charge to additional MOs, the energy of each MO is energy matched as a linear sum to the $B$ HO by contacting it through the bisector current of the intersecting MOs as described in the Methane Molecule $\left(\mathrm{CH}_{4}\right)$ section. The total energy of each alkyl borane given in Table 22.13 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 22.12 corresponding to functional-group composition of the molecule. $E_{\text {mag }}$ of Table 22.13 is given by Eqs. (15.15) and (22.3) for $B-H$. The bond angle parameters of alkyl boranes determined using

Eqs. (15.88-15.117) are given in Table 22.14. The charge-densities of exemplary alkyl boranes, trimethylborane, tetramethyldiborane, and methyldecaborane comprising the concentric shells of atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 22.2A-B and 22.3A-B, respectively.

Figure 22.2. A. Trimethylborane. Color scale, translucent views of the charge-density of $\left(\mathrm{H}_{3} \mathrm{C}\right)_{3} B$ showing the orbitals of the $B$ and $C$ atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei (red, not to scale). B. Tetramethyldiborane. Color scale, opaque view of the charge-density of $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{BH}_{2} \mathrm{~B}\left(\mathrm{CH}_{3}\right)_{2}$ showing the orbitals of the B and $C$ atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei (red, not to scale).

Figure 22.3. A-B. Methyldecaborane. Color scale, translucent view of the charge-density of methyldecaborane showing the orbitals of the $B$ and $C$ atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 22.9. The symbols of the functional groups of alkyl boranes.

| Functional Group | Group Symbol |
| :---: | :---: |
| $C-B$ bond | $C-B$ |
| $B H$ bond | $B-H$ |
| $B H B$ (bridged $H$ ) | $B-H-B$ |
| $B B$ bond | $B-B$ |
| $B B B$ (bridged $B$ ) | $B-B-B$ |
| $C C$ (aromatic bond) | $C \stackrel{3 e}{=} C$ |

## ALKOXY BORANES ( $(R O)_{x} B_{y} H_{z} ; R=$ alkyl) AND ALKYL BORINIC ACIDS ( $\left.(R O)_{q} B_{r} H_{s}(H O)_{t}\right)$

The alkoxy boranes and borinic acids each comprise a $B-O$ functional group, at least one boron-alkyl-ether moiety or one or more hydroxyl groups, respectively, and in some cases one or more alkyl groups and borane moieties. Each alkoxy moiety, $C_{n} H_{2 n+1} O$, of alkoxy boranes comprises one of two types of $\mathrm{C}-\mathrm{O}$ functional groups that are equivalent to those given in the Ethers $\left(C_{n} H_{2 n+2} O_{m}, n=2,3,4,5 \ldots \infty\right)$ section. One is for methyl or t-butyl groups, and the other is for general alkyl groups. Each hydroxyl functional group of borinic acids and alkyl borinic acids is equivalent to that given in the Alcohols $\left(C_{n} H_{2 n+2} O_{m}, n=1,2,3,4,5 \ldots \infty\right)$ section. The alkyl portion may be part of the alkoxy moiety, or an alkyl group may be bound to the central boron atom by a carbon-boron single bond comprising the $C-B$ group of the Alkyl Boranes $\left(R_{x} B_{y} H_{z} ; R=\right.$ alkyl $)$ section. Each alkyl portion may comprise at least a terminal methyl group ( $\mathrm{CH}_{3}$ ) and methylene ( $\mathrm{CH}_{2}$ ), methylyne ( CH ), and $C-C$ functional groups. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. Additional $R$ groups include aromatics such as phenyl. These groups in alkoxy boranes and alkyl borinic acids are equivalent to those in branched-chain alkanes and aromatics given in the corresponding sections. Furthermore, $B-H, B-B, B-H-B$, and $B-B-B$ groups may be present that are equivalent to those in boranes as given in the Boranes $\left(B_{x} H_{y}\right)$ section.

The MO semimajor axes of the $B-O$ functional groups of alkoxy alkanes and borinic acids are determined from the force balance equation of the centrifugal, Coulombic, and magnetic forces as given in the Boranes ( $B_{x} H_{y}$ ) section. In each case, the distance from the origin of the $H_{2}$-type-ellipsoidal-MO to each focus $c^{\prime}$, the internuclear distance $2 c^{\prime}$, and the length of the semiminor axis of the prolate spheroidal $H_{2}$-type MO $b=c$ are solved from the semimajor axis $a$. Then, the geometric and energy parameters of each MO are calculated using Eqs. (15.1-15.117).

The parameters of the force balance equation for the $\sigma$-MO of the $B-O$-bond MO in Eqs. (22.18-22.22) are $n_{e}=2$ and $|L|=0$ :

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \tag{22.41}
\end{equation*}
$$

From Eq. (22.41), the semimajor axis of the $B-O$-bond MO is:

$$
\begin{equation*}
a=2 a_{0} \tag{22.42}
\end{equation*}
$$

For the $B-O$ functional groups, hybridization of the $2 s$ and $2 p$ AOs of each $C$ and $B$ to form single $2 s p^{3}$ shells forms an energy minimum, and the sharing of electrons between the $C 2 s p^{3}$ and $B 2 s p^{3}$ HOs to form a MO permits each participating orbital to decrease in radius and energy. The energy of boron is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, in $c_{1}$ and $c_{2}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $C_{2}$ parameter. The approach to the hybridization factor of $O$ to $B$ in boric acids is similar to that of the $O$ to $S$ bonding in the $S O$ group of sulfoxides. The $O$ AO has an energy of $E(O)=-13.61805 \mathrm{eV}$, and the $B 2 s p^{3}$ HOs has an energy of $E\left(B, 2 s p^{3}\right)=-11.80624 \mathrm{eV}$ (Eq. (22.7)). To meet the equipotential condition of the union of the $B-O H_{2}$-type-ellipsoidal-MO with these orbitals in borinic acids and to energy match the OH group, the hybridization factor $\mathrm{C}_{2}$ of Eq. (15.61) for the $B-O$-bond MO given by Eq. (15.77) is:

$$
\begin{equation*}
C_{2}\left(O A O \text { to } B 2 s p^{3} H O\right)=\frac{E(O A O)}{E\left(B, 2 s p^{3}\right)}=\frac{-13.61805 \mathrm{eV}}{-11.80624 \mathrm{eV}}=1.15346 \tag{22.43}
\end{equation*}
$$

Since the energy of the MO is matched to that of the $B 2 s p^{3} \mathrm{HO}, E(A O / H O)$ in Eqs. (15.51) and (15.61) is $E\left(B, 2 s p^{3}\right)$ given by Eq. (22.7), and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -1.12740 eV corresponding to the independent single-bond charge contribution (Eq. (22.12)) of one center.

The parameters of the $B-O$ functional group of alkoxy boranes are the same as those of borinic acids except for $C_{1}$ and $C_{2}$. Rather than being bound to an $H$, the oxygen is bound to a $C 2 s p^{3} \mathrm{HO}$, and consequently, the hybridization of the $C-O$ given by Eq. (15.133) includes the $C 2 s p^{3} \mathrm{HO}$ hybridization factor of 0.91771 (Eq. (13.430)). To meet the equipotential condition of the union of the $\mathrm{B}-\mathrm{O} \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with the $B 2 s p^{3} \mathrm{HOs}$ having an energy of $E\left(B, 2 s p^{3}\right)=-11.80624 \mathrm{eV}$ (Eq. (22.7)) and the $O$ AO having an energy of $E(O)=-13.61805 \mathrm{eV}$ such that the hybridization
matches that of the $C-O$-bond MO, the hybridization factor $C_{2}$ of Eq. (15.61) for the $B-O$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
C_{2}\left(B 2 s p^{3} H O \text { to } O\right)=\frac{E\left(B, 2 s p^{3}\right)}{E(O)} c_{2}\left(C 2 s p^{3} H O\right)=\frac{-11.80624 \mathrm{eV}}{-13.61805 \mathrm{eV}}(0.91771)=0.79562 \tag{22.44}
\end{equation*}
$$

Furthermore, in order to form an energy minimum in the $B-O$-bond MO, oxygen acts as an $H$ in bonding with $B$ since the $2 p$ shell of $O$ is at the Coulomb energy between an electron and a proton (Eq. (10.163)). In this case, $k^{\prime}$ is 0.75 as given by Eq. (13.59) such that $C_{1}=0.75$ in Eq. (15.61).

Consider next the radius of the HO due to the contribution of charge to more than one bond. The energy contribution due to the charge donation at each boron atom and oxygen atom superimposes linearly. In general, since the energy of the $B 2 s p^{3}$ HO and $O \mathrm{AO}$ is matched to that of the $C 2 s p^{3} \mathrm{HO}$ when the molecule contains a $C-B$-bond MO and a $C-O$-bond MO, respectively, the corresponding radius $r_{\text {mol2sp }}$ of the $B 2 s p^{3} \mathrm{HO}$ of a boron atom, the $C 2 s p^{3} \mathrm{HO}$ of a carbon atom, and the $O$ AO of a given alkoxy borane or borinic acid molecule is calculated after Eq. (15.32) by considering $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$, the total energy donation to all bonds with which it participates in bonding. The Coulombic energy $E_{\text {Coulomb }}\left(\right.$ atom, $\left.2 s p^{3}\right)$ of the outer electron of the atom $2 s p^{3}$ shell considering the charge donation to all participating bonds is given by Eq. (15.14). In the case that the boron or oxygen atom is not bound to a $C 2 s p^{3} \mathrm{HO}, r_{\text {mol2 } 2 p^{3}}$ is calculated using Eq. (15.31) where $E_{\text {Coulomb }}\left(\right.$ atom, $\left.m s p^{3}\right)$ is $E_{\text {Coulomb }}\left(B 2 s p^{3}\right)=-11.89724 \mathrm{eV}$ and $E(O)=-13.61805 \mathrm{eV}$, respectively.

The symbols of the functional groups of alkoxy boranes and borinic acids are given in Table 22.15. The geometrical (Eqs. (15.1-15.5) and (22.42-22.44)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eq. (15.61), (22.4), (22.7), (22.12), (22.29), and (22.43-22.44)) parameters of alkoxy boranes and borinic acids are given in Tables 22.16, 22.17, and 22.18, respectively. In the case that the MO does not intercept the $B \mathrm{HO}$ due to the reduction of the radius from the donation of $B 2 s p^{3}$ HO charge to additional MO's, the energy of each MO is energy matched as a linear sum to the $B$ HO by contacting it through the bisector current of the intersecting MOs as described in the Methane Molecule $\left(\mathrm{CH}_{4}\right)$ section. The total energy of each alkyl borane given in Table 22.19 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 22.18 corresponding to functional-group composition of the molecule. $E_{\text {mag }}$ of Table 22.18 is given by Eqs. (15.15) and (22.3) for the $B-O$ groups and the $B-H, B-B, B-H-B$, and $B-B-B$ groups. $E_{m a g}$ of Table 22.18 is given by Eqs. (15.15) and (10.162) for the $O H$ group. The bond angle parameters of alkoxy boranes and borinic acids determined using Eqs. (15.8815.117) are given in Table 22.20. The charge-densities of exemplary alkoxy borane, trimethoxyborane, boric acid, and phenylborinic anhydride comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 22.4, 22.5, and 22.6, respectively.

Figure 22.4. Trimethoxyborane. Color scale, translucent views of the charge-density of $\left(\mathrm{H}_{3} \mathrm{CO}\right)_{3} B$ showing the orbitals of the $B, O$, and $C$ atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei (red, not to scale).

$0 \square 1 \mathrm{e} / \AA^{2}$

Figure 22.5. Boric Acid. Color scale, translucent view of the charge-density of $(\mathrm{HO})_{3} B$ showing the orbitals of the $B$ and $O$ atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei (red, not to scale).

Figure 22.6. Phenylborinic Anhydride. Color scale, translucent view of the charge-density of phenylborinic anhydride showing the orbitals of the $B$ and $O$ atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei (red, not to scale).

$0 \square 1 \mathrm{e} / \AA^{2}$

Table 22.15. The symbols of the functional groups of alkoxy boranes and borinic acids.

| Functional Group | Group Symbol |
| :--- | :--- |
| $\mathrm{B}-\mathrm{O}$ bond (borinic acid) | $\mathrm{B}-\mathrm{O}$ (i) |
| $\mathrm{B}-\mathrm{O}$ bond (alkoxy borane) | $\mathrm{B}-\mathrm{O}$ (ii) |
| OH group | OH |
| $\mathrm{C}-\mathrm{O}\left(\mathrm{CH}_{3}-\mathrm{O}-\right.$ and $\left.\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}-\mathrm{O}-\right)$ | $\mathrm{C}-\mathrm{O}$ (i) |
| $\mathrm{C}-\mathrm{O}$ (alkyl) | $\mathrm{C}-\mathrm{O}$ (ii) |

Table 22.19. The total bond energies of alkoxy boranes and borinic acids calculated using the functional group composition and the energies of Table 22.18 compared to the experimental values.

Table 22.20. The bond angle parameters of alkoxy boranes and borinic acids and experimental values. $H_{t}$ is a terminal or two-center $H . H_{b}$ is a bridge or three-center $H$. In the calculation of $\theta_{v}$, the parameters from the preceding angle were used. The experimental alkyl angle from Ref. [10]. $E_{T}$ is $E_{T}$ (atom - atom msp ${ }^{3} . A O$ ).

## TERTIARY AND QUATERNARY AMINOBORANES AND BORANE AMINES ( $R_{q} B_{r} N_{s} R_{t} ; R=H ;$ alkyl)

The tertiary and quaternary amino boranes and borane amines each comprise at least one $B$ bound by a boron-nitrogen single bond comprising a $B-N$ group, and may comprise at least a terminal methyl group $\left(\mathrm{CH}_{3}\right)$, as well other alkyl and borane groups such as methylene $\left(\mathrm{CH}_{2}\right)$, methylyne $(\mathrm{CH}), C-C, B-H, B-C, B-H, B-B, B-H-B$, and $B-B-B$ functional groups. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and tbutyl to t-butyl $C-C$ bonds comprise functional groups. These groups in tertiary and quaternary amino boranes and borane amines are equivalent to those in branched-chain alkanes, the $B-C$ group is equivalent to that of alkyl boranes, and the $B-H$, $B-B, B-H-B$, and $B-B-B$ functional groups are equivalent to those in boranes.

In tertiary amino boranes and borane amines, the nitrogen atom of each $B-N$ bond is bound to two other atoms such that there are a total of three bounds per atom. The amino or amine moiety may comprise $N H_{2}, N(H) R$, and $N R_{2}$. The corresponding functional group for the $\mathrm{NH}_{2}$ moiety is the $\mathrm{NH}_{2}$ functional group given in the Primary Amines $\left(C_{n} H_{2 n+2+m} N_{m}, n=1,2,3,4,5 \ldots \infty\right)$ section. The $N(H) R$ moiety comprises the $N H$ functional group of the Secondary Amines $\left(C_{n} H_{2 n+2+m} N_{m}, n=2,3,4,5 \ldots \infty\right)$ section and the $C-N$ functional group of the Primary Amines $\left(C_{n} H_{2 n+2+m} N_{m}, n=1,2,3,4,5 \ldots \infty\right)$ section. The $N R_{2}$ moiety comprises two types of $C-N$ functional groups, one for the methyl group corresponding to the $C$ of $C-N$ and the other for general alkyl secondary amines given in the Secondary Amines $\left(C_{n} H_{2 n+2+m} N_{m}, \quad n=2,3,4,5 \ldots \infty\right)$ section.

In quaternary amino boranes and borane amines, the nitrogen atom of each $B-N$ bond is bound to three other atoms such that there are a total of four bonds per atom. The amino or amine moiety may comprise $N H_{3}, N\left(H_{2}\right) R, N(H) R_{2}$, and $N R_{3}$. The corresponding functional group for the $\mathrm{NH}_{3}$ moiety is ammonia given in the Ammonia $\left(\mathrm{NH}_{3}\right)$ section. The $N\left(\mathrm{H}_{2}\right) R$ moiety comprises the $\mathrm{NH}_{2}$ and the $\mathrm{C}-\mathrm{N}$ functional groups given in the Primary Amines $\left(C_{n} H_{2 n+2+m} N_{m}, n=1,2,3,4,5 \ldots \infty\right)$ section. The $N(H) R_{2}$ moiety comprises the $N H$ functional group and two types of $C-N$ functional groups, one for the methyl group corresponding to the $C$ of $C-N$ and the other for general alkyl secondary amines given in the Secondary Amines $\left(C_{n} H_{2 n+2+m} N_{m}, n=2,3,4,5 \ldots \infty\right)$ section. The $N R_{3}$ moiety comprises the $C-N$ functional group of tertiary amines given in the Tertiary Amines $\left(C_{n} H_{2 n+3} N, n=3,4,5 \ldots \infty\right)$ section.

The bonding in the $B-N$ functional groups of tertiary and quaternary amino boranes and borane amines is similar to that of the $B-O$ groups of alkoxy boranes and borinic acids given in the corresponding section. The MO semimajor axes of the $B-N$ functional groups are determined from the force balance equation of the centrifugal, Coulombic, and magnetic forces as given in the Boranes $\left(B_{x} H_{y}\right)$ section. In each case, the distance from the origin of the $H_{2}$-type-ellipsoidal-MO to each focus $c^{\prime}$, the internuclear distance $2 c^{\prime}$, and the length of the semiminor axis of the prolate spheroidal $H_{2}$-type MO $b=c$ are solved from the semimajor axis $a$. Then, the geometric and energy parameters of each MO are calculated using Eqs. (15.1-15.117).

As in the case of the $B-O$-bond MOs, the $\sigma$-MOs of the tertiary and quaternary $B-N$-bond MOs is energy matched to the $B 2 s p^{3} \mathrm{HO}$ which determines that the parameters of the force balance equation based on electron angular momentum are determined by those of the boron atom. Thus, the parameters of the force balance equation for the $\sigma-\mathrm{MO}$ of the $B-N$-bond MOs in Eqs. (22.18-22.22) are $n_{e}=1$ and $|L|=\frac{3 \sqrt{\frac{3}{4}}}{Z}$ corresponding to the three electrons of the boron atom:

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(\frac{1}{2}+\frac{3 \sqrt{\frac{3}{4}}}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{22.45}\\
& a=\left(\frac{3}{2}+\frac{3 \sqrt{\frac{3}{4}}}{Z}\right) a_{0} \tag{22.46}
\end{align*}
$$

With $Z=5$, the semimajor axis of the tertiary $B-N$-bond MO is:

$$
\begin{equation*}
a=2.01962 a_{0} \tag{22.47}
\end{equation*}
$$

For the $B-N$ functional groups, hybridization of the $2 s$ and $2 p$ AOs of $B$ to form single $2 s p^{3}$ shells forms an energy minimum, and the sharing of electrons between the $B 2 s p^{3} \mathrm{HO}$ and $N$ AO to form a MO permits each participating orbital to decrease in radius and energy. The energy of boron is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, in $c_{1}$ and $c_{2}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $C_{1}$ and
$C_{2}$ parameters. The $N$ AO has an energy of $E(N)=-14.53414 \mathrm{eV}$, and the $B 2 s p^{3}$ HOs have an energy of $E\left(B, 2 s p^{3}\right)=-11.80624 \mathrm{eV}$ (Eq. (22.7)). To meet the equipotential condition of the union of the $B-N H_{2}$-type-ellipsoidalMO with these orbitals, the hybridization factor $C_{2}$ of Eq. (15.61) for the $B-N$-bond MO given by Eq. (15.77) is:

$$
\begin{equation*}
C_{2}\left(N A O \text { to } B 2 s p^{3} H O\right)=\frac{E\left(B, 2 s p^{3}\right)}{E(N A O)}=\frac{-11.80624 \mathrm{eV}}{-14.53414 \mathrm{eV}}=0.81231 \tag{22.48}
\end{equation*}
$$

Since the energy of the MO is matched to that of the $B 2 s p^{3} \mathrm{HO}, E(A O / H O)$ in Eqs. (15.51) and (15.61) is $E\left(B, 2 s p^{3}\right)$ given by Eq. (22.7), and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ for ternary $B-N$ is -1.12740 eV corresponding to the independent single-bond charge contribution (Eq. (22.12)) of one center as in the case of the alkoxy borane $B-O$ functional group. Furthermore, $k^{\prime}$ is 0.75 as given by Eq. (13.59) such that $C_{1}=0.75$ in Eq. (15.61) which is also equivalent to $C_{1}$ of the $B-O$ alkoxy borane group.
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the quaternary $B-N$-bond MO is determined by considering that the bond involves an electron transfer from the nitrogen atom to the boron atom to form zwitterions such as $R_{3} N^{+}-B^{-} R_{3}^{\prime}$. By considering the electron redistribution in the quaternary amino borane and borane amine molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{B-N b o r a n e 2 s p^{3}}$ of the $B 2 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18) , except that the sign of the charge donation is positive:

$$
\begin{equation*}
r_{B-\text { Nborane } 2 s p^{3}}=\left(\sum_{n=2}^{4}(Z-n)+1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 74.89168 \mathrm{eV})}=\frac{7 e^{2}}{8 \pi \varepsilon_{0}(e 74.89168 \mathrm{eV})}=1.27171 a_{0} \tag{22.49}
\end{equation*}
$$

Using Eqs. (15.19) and (22.49), the Coulombic energy $E_{\text {Coulomb }}\left(B_{B-N b o r a n e}, 2 s p^{3}\right)$ of the outer electron of the $B 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(B_{B-N b o r a n e}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{B-\text { Nborane } 2 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.27171 a_{0}}=-10.69881 \mathrm{eV} \tag{22.50}
\end{equation*}
$$

During hybridization, one of the spin-paired $2 s$ electrons is promoted to the $B 2 s p^{3}$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (22.6). Using Eqs. (22.6) and (22.50), the energy $E\left(B_{B-N b o r a n e}, 2 s p^{3}\right)$ of the outer electron of the $B 2 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(B_{B-\text { Nborane }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{B-N b o r a n e 2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-10.69881 \mathrm{eV}+0.09100 \mathrm{eV}=-10.60781 \mathrm{eV} \tag{22.51}
\end{equation*}
$$

Thus, $E_{T}\left(B-N, 2 s p^{3}\right)$, the energy change of each $B 2 s p^{3}$ shell with the formation of the $B-N$-bond MO is given by the difference between Eq. (22.51) and Eq. (22.7).

$$
\begin{equation*}
E_{T}\left(B-N, 2 s p^{3}\right)=E\left(B_{B-\text { Nborane }}, 2 s p^{3}\right)-E\left(B, 2 s p^{3}\right)=-10.60781 \mathrm{eV}-(-11.80624 \mathrm{eV})=1.19843 \mathrm{eV} \tag{22.52}
\end{equation*}
$$

Thus, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the quaternary $B-N$-bond MO is 1.19843 eV .
Consider next the radius of the HO due to the contribution of charge to more than one bond. The energy contribution due to the charge donation at each boron atom and nitrogen atom superimposes linearly. In general, since the energy of the $B 2 s p^{3}$ HO and $N \mathrm{AO}$ is matched to that of the $C 2 s p^{3} \mathrm{HO}$ when a molecule contains a $C-B$-bond MO and a $C-N$-bond MO, respectively, the corresponding radius $r_{m o l 2 s p^{3}}$ of the $B 2 s p^{3} \mathrm{HO}$ of a boron atom, the $C 2 s p^{3} \mathrm{HO}$ of a carbon atom, and the $N$ AO of a given $B-N$-containing borane molecule is calculated after Eq. (15.32) by considering $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$, the total energy donation to all bonds with which it participates in bonding. The Coulombic energy $E_{\text {Coulomb }}\left(\right.$ atom, $\left.2 s p^{3}\right)$ of the outer electron of the atom $2 s p^{3}$ shell considering the charge donation to all participating bonds is given by Eq. (15.14). In the case that the boron or nitrogen atom is not bound to a $C 2 s p^{3} \mathrm{HO}, r_{m o l 2 s p^{3}}$ is calculated using Eq. (15.31) where $E_{\text {Coulomb }}\left(\right.$ atom, $\left.m s p^{3}\right)$ is $E_{\text {Coulomb }}\left(B 2 s p^{3}\right)=-11.89724 \mathrm{eV}$ and $E(N)=-14.53414 \mathrm{eV}$, respectively. The hybridization parameters used in Eqs. (15.88-15.117) for the determination of bond angles of tertiary and quaternary amino boranes and borane amines are given in Table 22.21.

Table 22.21. Atom hybridization designation (\# first column) and hybridization parameters of atoms for determination of bond angles with final values of $r_{2 s p^{3}}, E_{\text {Coulomb }}\left(\right.$ atom, $\left.2 s p^{3}\right)$ (designated as $\left.E_{\text {Coulomb }}\right)$, and $E\left(\right.$ atom $\left.{ }_{B-\text { Nborane }} 2 s p^{3}\right)($ designated as $E)$
calculated using the appropriate values of $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$ (designated as $E_{T}$ ) for each corresponding terminal bond spanning each angle.

The symbols of the functional groups of tertiary and quaternary amino boranes and borane amines are given in Table 22.22. The geometrical (Eqs. (15.1-15.5) and (22.47)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eq. (15.61), (22.4), (22.7), (22.12), (22.48), and (22.52)) parameters of tertiary and quaternary amino boranes and borane amines are given in Tables 22.23, 22.24, and 22.25 , respectively. In the case that the MO does not intercept the $B \mathrm{HO}$ due to the reduction of the radius from the donation of $B 2 s p^{3} \mathrm{HO}$ charge to additional MOs, the energy of each MO is energy matched as a linear sum to the $B \mathrm{HO}$ by contacting it through the bisector current of the intersecting MOs as described in the Methane Molecule $\left(\mathrm{CH}_{4}\right)$ section. The total energy of each tertiary and quaternary amino borane or borane amine given in Table 22.26 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 22.25 corresponding to functional-group composition of the molecule. $E_{\text {mag }}$ of Table 22.26 is given by Eqs. (15.15) and (22.3) for the $B-N$ groups and the $B-H, B-B$, $B-H-B$, and $B-B-B$ groups. $E_{\operatorname{mag}}$ of Table 22.26 is given by Eqs. (15.15) and (10.142) for $N H_{3}$. The bond angle parameters of tertiary and quaternary amino boranes and borane amines determined using Eqs. (15.88-15.117) are given in Table 22.27. The charge-densities of exemplary tertiary amino borane, tris(dimethylamino)borane and quaternary amino borane, trimethylaminotrimethylborane comprising the concentric shells of atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 22.7 and 22.8, respectively.

Figure 22.7. Trisdimethylaminoborane. Color scale, opaque views of the charge-density of $\left(\left(\mathrm{H}_{3} \mathrm{C}\right)_{2} \mathrm{~N}\right)_{3} B$ showing the orbitals of the $B, N$, and $C$ atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei (red, not to scale).

Figure 22.8. Trimethylaminotrimethylborane. Color scale, opaque view of the charge-density of $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{BN}_{3}\left(\mathrm{CH}_{3}\right)_{3}$ showing the orbitals of the $B, N$, and $C$ atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 22.27. The bond angle parameters of tertiary and quaternary amino boranes and borane amines and experimental values. $H_{t}$ is a terminal or two-center $H_{\text {. }} H_{b}$ is a bridge or three-center $H$. In the calculation of $\theta_{v}$, the parameters from the preceding angle were used. $E_{T}$ is $E_{T}$ (atom-atom $\mathrm{msp}{ }^{3} . A O$ ).

## HALIDOBORANES

The halidoboranes each comprise at least one $B$ bound by a boron-halogen single bond comprising a $B-X$ group where $X=F, C l, B r, I$, and may further comprise one or more alkyl groups and borane moieties. The latter comprise alkyl and aryl moieties and $B-C, B-H, B-B, B-H-B$, and $B-B-B$ functional groups wherein the $B-C$ group is equivalent to that of alkyl boranes, and the $B-H, B-B, B-H-B$, and $B-B-B$ functional groups are equivalent to those in boranes given in the corresponding sections. Alkoxy boranes and borinic acids moieties given in the Alkoxy Boranes and Alkyl Borinic Acids $\left((R O)_{q} B_{r} H_{s}(H O)_{t}\right)$ section may be bound to the $B-X$ group by a $B-O$ functional group. The former further comprise at least one boron-alkyl-ether moiety, and the latter comprise one or more hydroxyl groups, respectively. Each alkoxy moiety, $C_{n} H_{2 n+1} O$, comprises one of two types of $C-O$ functional groups that are equivalent to those given in the Ethers $\left(C_{n} H_{2 n+2} O_{m}, n=2,3,4,5 \ldots \infty\right)$ section. One is for methyl or t-butyl groups, and the other is for general alkyl groups. Each borinic acid hydroxyl functional group is equivalent to that given in the Alcohols ( $C_{n} H_{2 n+2} O_{m}, n=1,2,3,4,5 \ldots \infty$ ) section.

Tertiary amino-borane and borane-amine moieties given in the Tertiary and Quaternary Aminoboranes and Borane Amines ( $R_{q} B_{r} N_{s} R_{t} ; R=H ;$ alkyl) section can be bound to the $B-X$ group by a $B-N$ functional group. The nitrogen atom of each $B-N$ functional group is bound to two other atoms such that there are a total of three bonds per atom. The amino or amine moiety may comprise $\mathrm{NH}_{2}, \mathrm{~N}(\mathrm{H}) \mathrm{R}$, and $\mathrm{NR}_{2}$. The corresponding functional group for the $\mathrm{NH}_{2}$ moiety is the $\mathrm{NH}_{2}$ functional group given in the Primary Amines $\left(C_{n} H_{2 n+2+m} N_{m}, n=1,2,3,4,5 \ldots \infty\right)$ section. The $N(H) R$ moiety comprises the NH functional group of the Secondary Amines $\left(C_{n} H_{2 n+2+m} N_{m}, n=2,3,4,5 \ldots \infty\right)$ section and the $C-N$ functional group of the Primary Amines $\left(C_{n} H_{2 n+2+m} N_{m}, n=1,2,3,4,5 \ldots \infty\right)$ section. The $N R_{2}$ moiety comprises two types of $C-N$ functional groups, one for the methyl group corresponding to the $C$ of $C-N$ and the other for general alkyl secondary amines given in the Secondary Amines ( $\left.C_{n} H_{2 n+2+m} N_{m}, \quad n=2,3,4,5 \ldots \infty\right)$ section.

Quaternary amino-borane and boraneamine moieties given in the Tertiary and Quaternary Aminoboranes and Borane Amines $\left(R_{q} B_{r} N_{s} R_{t} ; R=H ;\right.$ alkyl) section can be bound to the $B-X$ group by a $B-N$ functional group. The nitrogen atom of each $B-N$ bond is bound to three other atoms such that there are a total of four bonds per atom. The amino or amine moiety may comprise $\mathrm{NH}_{3}, N\left(\mathrm{H}_{2}\right) \mathrm{R}, \mathrm{N}(\mathrm{H}) \mathrm{R}_{2}$, and $\mathrm{NR}_{3}$. The corresponding functional group for the $\mathrm{NH}_{3}$ moiety is ammonia given in the Ammonia $\left(\mathrm{NH}_{3}\right)$ section. The $\mathrm{N}\left(\mathrm{H}_{2}\right) R$ moiety comprises the $\mathrm{NH}_{2}$ and the $\mathrm{C}-\mathrm{N}$ functional groups given in the Primary Amines $\left(C_{n} H_{2 n+2+m} N_{m}, n=1,2,3,4,5 \ldots \infty\right)$ section. The $N(H) R_{2}$ moiety comprises the $N H$ functional group and two types of $C-N$ functional groups, one for the methyl group corresponding to the $C$ of $C-N$ and the other for general alkyl secondary amines given in the Secondary Amines $\left(C_{n} H_{2 n+2+m} N_{m}, n=2,3,4,5 \ldots \infty\right)$ section. The $N R_{3}$ moiety comprises the $C-N$ functional group of tertiary amines given in the Tertiary Amines ( $\left.C_{n} H_{2 n+3} N, n=3,4,5 \ldots \infty\right)$ section.

The alkyl portion may be part of the alkoxy moiety, amino or amine moiety, or an alkyl group, or it may be bound to the central boron atom by a carbon-boron single bond comprising the $C-B$ group of the Alkyl Boranes $\left(R_{x} B_{y} H_{z} ; R=\right.$ alkyl $)$ section. Each alkyl portion may comprise at least a terminal methyl group $\left(\mathrm{CH}_{3}\right)$ and methylene $\left(\mathrm{CH}_{2}\right)$, methylyne ( CH ), and $C-C$ functional groups. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. Additional $R$ groups include aromatics such as phenyl and $-\mathrm{HC}=\mathrm{CH}_{2}$. These groups in halidobroanes are equivalent to those in branched-chain alkanes, aromatics, and alkenes given in the corresponding sections.

The bonding in the $B-X$ functional groups of halidoboranes is similar to that of the $B-O$ and $B-N$ groups of alkoxy boranes and borinic acids and tertiary and quaternary amino boranes and borane amines given in the corresponding sections. The MO semimajor axes of the $B-X$ functional groups are determined from the force balance equation of the centrifugal, Coulombic, and magnetic forces as given in the Boranes $\left(B_{x} H_{y}\right)$ section. In each case, the distance from the origin of the $H_{2}-$ type-ellipsoidal-MO to each focus $c^{\prime}$, the internuclear distance $2 c^{\prime}$, and the length of the semiminor axis of the prolate spheroidal $H_{2}$-type MO $b=c$ are solved from the semimajor axis $a$. Then, the geometric and energy parameters of each MO are calculated using Eqs. (15.1-15.117).

As in the case of the $B-O$ - and $B-N$-bond MOs, the $\sigma$-MOs of the $B-X$-bond MOs are energy matched to the $B 2 s p^{3} \mathrm{HO}$ which determines that the parameters of the force balance equation based on electron angular momentum are determined by those of the boron atom. The parameters of the force balance equation for the $\sigma-\mathrm{MO}$ of the $B-F$-bond MO in Eqs. (22.18-22.22) are $n_{e}=1$ and $|L|=0$ :

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(\frac{1}{2}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \tag{22.53}
\end{equation*}
$$

From Eq. (22.53), the semimajor axis of the tertiary $B-F$-bond MO is
$a=1.5 a_{0}$
The force balance equation for each $\sigma$-MO of the $B-C l$ is equivalent to that of the $B-B$-bond MO with $n_{e}=2$ and $|L|=3 \sqrt{\frac{3}{4}} \hbar$ corresponding to three electrons of the $B 2 s p^{3}$ shell is:

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(1+\frac{3 \sqrt{\frac{3}{4}}}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{22.55}\\
& a=\left(2+\frac{3 \sqrt{\frac{3}{4}}}{Z}\right) a_{0} \tag{22.56}
\end{align*}
$$

With $Z=5$, the semimajor axis of the $B-C l$-bond MO is:

$$
\begin{equation*}
a=2.51962 a_{0} \tag{22.57}
\end{equation*}
$$

The hybridization of the bonding in the $B-X$ functional groups of halidoboranes is similar to that of the $C-X$ groups of alkyl halides given in the corresponding sections. For the $B-X$ functional groups, hybridization of the $2 s$ and $2 p$ AOs of $B$ to form single $2 s p^{3}$ shells forms an energy minimum, and the sharing of electrons between the $B 2 s p^{3} \mathrm{HO}$ and $X$ AO to form a MO permits each participating orbital to decrease in radius and energy. The $F$ AO has an energy of $E(F)=-17.42282 \mathrm{eV}$, and the $B 2 s p^{3}$ HOs have an energy of $E\left(B, 2 s p^{3}\right)=-11.80624 \mathrm{eV}$ (Eq. (22.7)). To meet the equipotential condition of the union of the $B-F \quad H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $B-F$-bond MO given by Eq. (15.77) is:

$$
\begin{equation*}
c_{2}\left(F A O \text { to } B 2 s p^{3} H O\right)=\frac{E\left(B, 2 s p^{3}\right)}{E(F A O)}=\frac{-11.80624 \mathrm{eV}}{-17.42282 \mathrm{eV}}=0.68285 \tag{22.58}
\end{equation*}
$$

Since the energy of the MO is matched to that of the $B 2 s p^{3} \mathrm{HO}, E(A O / H O)$ in Eqs. (15.51) and (15.61) is $E\left(B, 2 s p^{3}\right)$ given by Eq. (22.7).
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} \cdot A O\right)$ of the $B-F$-bond MO is determined by considering that the bond involves an electron transfer from the boron atom to the fluorine atom to form zwitterions such as $H_{2} B^{+}-F^{-}$. By considering the electron redistribution in the fluoroborane as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{B-F b o r a n e 2 s p^{3}}$ of the $B 2 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$
\begin{equation*}
r_{B-F b o r a n e 2 s p^{3}}=\left(\sum_{n=2}^{4}(Z-n)-1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 74.89168 \mathrm{eV})}=\frac{5 e^{2}}{8 \pi \varepsilon_{0}(e 74.89168 \mathrm{eV})}=0.90837 a_{0} \tag{22.59}
\end{equation*}
$$

Using Eqs. (15.19) and (22.13), the Coulombic energy $E_{\text {Coulomb }}\left(B_{B-F b o r a n e}, 2 s p^{3}\right)$ of the outer electron of the $B 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(B_{B-F b o r a n e}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{B-F b o r a n e 2 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.90837 a_{0}}=-14.97834 \mathrm{eV} \tag{22.60}
\end{equation*}
$$

During hybridization, one of the spin-paired $2 s$ electrons is promoted to the $B 2 s p^{3}$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (22.6). Using Eqs. (22.6) and (22.60), the energy $E\left(B_{B-X b o r a n e}, 2 s p^{3}\right)$ of the outer electron of the $B 2 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(B_{B-F b o r a n e}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{B-F b o r a n e 2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-14.97834 \mathrm{eV}+0.09100 \mathrm{eV}=-14.88734 \mathrm{eV} \tag{22.61}
\end{equation*}
$$

Thus, $E_{T}\left(B-F, 2 s p^{3}\right)$, the energy change of each $B 2 s p^{3}$ shell with the formation of the $B-F$-bond MO is given by the difference between Eq. (22.15) and Eq. (22.7).

$$
\begin{equation*}
E_{T}\left(B-F, 2 s p^{3}\right)=E\left(B_{B-F b o r a n e}, 2 s p^{3}\right)-E\left(B, 2 s p^{3}\right)=-14.88734 \mathrm{eV}-(-11.80624 \mathrm{eV})=-3.08109 \mathrm{eV} \tag{22.62}
\end{equation*}
$$

Thus, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ for ternary $B-F$ is -6.16219 eV corresponding to the maximum charge contribution of an electron given by two times Eq. (22.62).

In chloroboranes, the energies of chlorine and boron are less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{1}$ and $c_{2}$ in Eq. (15.61) are one, and the energy matching condition is determined by the $C_{2}$ parameter. The $C l \mathrm{AO}$ has an energy of $E(C l)=-12.96764 \mathrm{eV}$, and the $B 2 s p^{3}$ HOs have an energy of $E\left(B, 2 s p^{3}\right)=-11.80624 \mathrm{eV}$ (Eq. (22.7)). To meet the equipotential condition of the union of the $\mathrm{B}-\mathrm{Cl} \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $B-C l$-bond MO given by Eq. (15.77) is:

$$
\begin{equation*}
C_{2}\left(\text { ClAO to } B 2 s p^{3} H O\right)=\frac{E\left(B, 2 s p^{3}\right)}{E(C l A O)}=\frac{-11.80624 \mathrm{eV}}{-12.96764 \mathrm{eV}}=0.91044 \tag{22.63}
\end{equation*}
$$

Since the energy of the MO is matched to that of the $B 2 s p^{3} \mathrm{HO}, E(A O / H O)$ in Eqs. (15.51) and (15.61) is $E\left(B, 2 s p^{3}\right)$ given by Eq. (22.7), and $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ is given by two times Eq. (22.12) corresponding to the two centers.

Consider next the radius of the HO due to the contribution of charge to more than one bond. The energy contribution due to the charge donation at each boron atom and halogen atom superimposes linearly. In general, since the energy of the $B 2 s p^{3}$ HO and $X$ AO is matched to that of the $C 2 s p^{3} \mathrm{HO}$ when a molecule contains a $C-B$-bond MO and a $C-X$-bond MO, respectively, the corresponding radius $r_{m o l 2 s p^{3}}$ of the $B 2 s p^{3} \mathrm{HO}$ of a boron atom, the $C 2 s p^{3} \mathrm{HO}$ of a carbon atom, and the $X$ AO of a given halidoborane molecule is calculated after Eq. (15.32) by considering $\sum E_{T_{n o l}}\left(M O, 2 s p^{3}\right)$, the total energy donation to all bonds with which it participates in bonding. The Coulombic energy $E_{\text {Coulomb }}\left(\right.$ atom, $\left.2 s p^{3}\right)$ of the outer electron of the atom $2 s p^{3}$ shell considering the charge donation to all participating bonds is given by Eq. (15.14). In the case that the boron or halogen atom is not bound to a $C 2 s p^{3} \mathrm{HO}, r_{m o l 2 s p^{3}}$ is calculated using Eq. (15.31) where $E_{\text {Coulomb }}\left(\right.$ atom, $\left.m s p^{3}\right)$ is $E_{\text {Coulomb }}\left(B 2 s p^{3}\right)=-11.89724 \mathrm{eV}, E(F)=-17.42282 \mathrm{eV}$, or $E(C l)=-12.96764 \mathrm{eV}$. The hybridization parameters used in Eqs. (15.88-15.117) for the determination of bond angles of halidoboranes are given in Table 22.28.

Table 22.28. Atom hybridization designation (\# first column) and hybridization parameters of atoms for determination of bond angles with final values of $r_{2 s p^{3}}, E_{\text {Coulomb }}\left(\right.$ atom, $\left.2 s p^{3}\right)$ (designated as $\left.E_{\text {Coulomb }}\right)$, and $E\left(\right.$ atom $\left._{B-\text { Xborane }} 2 s p^{3}\right)$ (designated as $E$ ) calculated using the appropriate values of $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$ (designated as $E_{T}$ ) for each corresponding terminal bond spanning each angle.

| $\#$ | $E_{T}$ | $E_{T}$ | $E_{T}$ | $E_{T}$ | $E_{T}$ | $r_{3 \text { sp }}{ }^{3}$ <br> Final | $E_{\text {Coulomb }}$ <br> $(\mathrm{eV})$ <br> Final | $E$ <br> $(\mathrm{eV})$ <br> Final |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | -0.56370 | 0 | 0 | 0 | 0 | 0.95939 <br> (Eq. (15.31)) | -14.18175 |  |
| 2 | -3.08109 | -3.08109 | 0 | 0 | 0 | 0.75339 <br> (Eq. (15.31)) | -18.05943 | -17.96843 |

The symbols of the functional groups of halidoboranes are given in Table 22.29. The geometrical (Eqs. (15.1-15.5) and (22.47)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eq. (15.61), (22.4), (22.7), (22.12), (22.48), and (22.52)) parameters of halidoboranes are given in Tables 22.30, 22.31, and 22.32, respectively. In the case that the MO does not intercept the $B \mathrm{HO}$ due to the reduction of the radius from the donation of $B 2 s p^{3} \mathrm{HO}$ charge to additional MOs, the energy of each MO is energy matched as a linear sum to the $B$ HO by contacting it through the bisector current of the intersecting MOs as described in the Methane Molecule $\left(\mathrm{CH}_{4}\right)$ section. The total energy of each halidoborane given in Table 22.33 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 22.32 corresponding to functional-group composition of the molecule. $E_{\text {mag }}$ of Table 22.33 is given by Eqs. (15.15) and (22.3) for the $B-X$ groups and the $B-O, B-N, B-H, B-B, B-H-B$, and $B-B-B$ groups. $E_{\text {mag }}$ of Table 22.33 is given by Eqs. (15.15) and (10.162) for the $O H$ group. The bond angle parameters of halidoboranes determined using Eqs. (15.88-15.117) are given in Table 22.34. The charge-densities of exemplary fluoroborane, boron trifluoride and choloroborane, boron trichloride comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 22.9 and 22.10, respectively.

Figure 22.10. (A) Boron Trifluoride. Color scale, translucent view of the charge-density of $B F_{3}$ showing the orbitals of the $B$ and $F$ atoms at their radii, and the ellipsoidal surface of each $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond. (B) Boron Trichloride. Color scale, translucent views of the charge-density of $\mathrm{BCl}_{3}$ showing the orbitals of the B and Cl atoms at their radii, and the ellipsoidal surface of each $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond.

## SUMMARY TABLES OF BORON MOLECULES

The bond energies, calculated using closed-form equations having integers and fundamental constants only for classes of molecules whose designation is based on the main functional group, are given in the following tables with the experimental values.

Table 22.35.1. Summary results of boranes.

| Formula | Name | Calculated <br> Total Bond <br> Energy $(\mathrm{eV})$ | Experimental <br> Total Bond <br> Energy $(\mathrm{eV})$ | Relative <br> Error |
| :--- | :--- | :---: | :---: | :---: |
| BB | diboron | 3.12475 | 3.10405 | -0.00667 |
| $\mathrm{~B}_{2} \mathrm{H}_{6}$ | diborane | 24.94229 | 24.89030 | -0.00209 |
| $\mathrm{~B}_{4} \mathrm{H}_{10}$ | tetraborane(10) | 44.92160 | 45.33134 | 0.00904 |
| $\mathrm{~B}_{5} \mathrm{H}_{9}$ | pentaborane $(9)$ | 48.25462 | 48.85411 | 0.01227 |
| $\mathrm{~B}_{5} \mathrm{H}_{11}$ | pentaborane $(11)$ | 54.00546 | 53.06086 | -0.01780 |
| $\mathrm{~B}_{6} \mathrm{H}_{10}$ | hexaborane $(10)$ | 56.55063 | 56.74739 | 0.00347 |
| $\mathrm{~B}_{9} \mathrm{H}_{15}$ | nonaborane $(15)$ | 85.61380 | 84.95008 | -0.00781 |
| $\mathrm{~B}_{10} \mathrm{H}_{14}$ | decaborane $(14)$ | 89.73467 | 89.69790 | -0.00041 |

Table 22.35.2. Summary results of alkyl boranes.

# Chapter 23 

## ORGANOMETALLIC AND COORDINATE FUNCTIONAL GROUPS AND MOLECULES

## GENERAL CONSIDERATIONS OF THE ORGANOMETALLIC AND COORDINATE BOND

Organometallic and coordinate compounds comprising an arbitrary number of atoms can be solved using similar principles and procedures as those used to solve organic molecules of arbitrary length and complexity. Organometallic and coordinate compounds can be considered to be comprised of functional groups such as $M-C, M-H, M-X(X=F, C l, B r, I)$, $M-O H, M-O R$, and the alkyl functional groups of organic molecules. The solutions of these functional groups or any others corresponding to the particular organometallic or coordinate compound can be conveniently obtained by using generalized forms of the force balance equation given in the Force Balance of the $\sigma$ MO of the Carbon Nitride Radical section for molecules comprised of metal and atoms other than carbon and the geometrical and energy equations given in the Derivation of the General Geometrical and Energy Equations of Organic Chemistry section for organometallic and coordinate compounds comprised of carbon. The appropriate functional groups with their geometrical parameters and energies can be added as a linear sum to give the solution of any organometallic or coordinate compound.

## ALKYL ALUMINUM HYDRIDES ( $R_{n} A l H_{3-n}$ )

Similar to the case of carbon and silicon, the bonding in the aluminum atom involves four $s p^{3}$ hybridized orbitals formed from the outer $3 p$ and $3 s$ shells except that only three HOs are filled. In organoaluminum compounds, bonds form between a $A l 3 s p^{3} \mathrm{HO}$ and at least one $C 2 s p^{3} \mathrm{HO}$ and one or more $H 1 s$ AOs. The geometrical parameters of each $A l H$ functional group is solved from the force balance equation of the electrons of the corresponding $\sigma-\mathrm{MO}$ and the relationships between the prolate spheroidal axes. Then, the sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $A l 3 s p^{3}$ shell as in the case of the corresponding carbon and silicon molecules. As in the case of alkyl silanes given in the corresponding section, the sum of the energies of the $H_{2}$-type ellipsoidal MO of the $A l-C$ functional group is matched to that of the $A l 3 s p^{3}$ shell, and Eq. (15.51) is solved for the semimajor axis with $n_{1}=1$ in Eq. (15.50).

The energy of aluminum is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). A minimum energy is achieved while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical $(\mathrm{OH})$ section with the donation of $25 \%$ electron density from the participating $\mathrm{Al} 3 \mathrm{sp}{ }^{3} \mathrm{HO}$ to each $\mathrm{Al}-\mathrm{H}$-bond MO.

The $3 s p^{3}$ hybridized orbital arrangement after Eq. (13.422) is

$$
\begin{align*}
& 3 \mathrm{sp}^{3} \text { state } \\
& \begin{array}{llll}
\frac{\uparrow}{0,0} & \frac{\uparrow}{1,-1} & \frac{\uparrow}{1,0} & \\
1,1
\end{array} \tag{23.1}
\end{align*}
$$

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the three electrons. The sum $E_{T}\left(A l, 3 s p^{3}\right)$ of experimental energies [1] of $A l, A l^{+}$, and $A l^{2+}$ is

$$
\begin{equation*}
E_{T}\left(A l, 3 s p^{3}\right)=-(28.44765 \mathrm{eV}+18.82856 \mathrm{eV}+5.98577 \mathrm{eV})=-53.26198 \mathrm{eV} \tag{23.2}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 s p^{3}}$ of the
$A l 3 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13):

$$
\begin{equation*}
r_{3 s p^{3}}=\sum_{n=10}^{12} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 53.26198 \mathrm{eV})}=\frac{6 e^{2}}{8 \pi \varepsilon_{0}(e 53.26198 \mathrm{eV})}=1.53270 a_{0} \tag{23.3}
\end{equation*}
$$

where $Z=13$ for aluminum. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(A l, 3 s p^{3}\right)$ of the outer electron of the $A l 3 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(A l, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.53270 a_{0}}=-8.87700 \mathrm{eV} \tag{23.4}
\end{equation*}
$$

During hybridization, the spin-paired $3 s$ electrons are promoted to the $A l 3 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (15.15) at the initial radius of the $3 s$ electrons. From Eq. (10.255) with $Z=13$, the radius $r_{12}$ of the Al3s shell is:

$$
\begin{equation*}
r_{12}=1.41133 a_{0} \tag{23.5}
\end{equation*}
$$

Using Eqs. (15.15) and (23.5), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{12}\right)^{3}}=\frac{8 \pi \mu_{o} \mu_{B}^{2}}{\left(1.41133 a_{0}\right)^{3}}=0.04070 \mathrm{eV} \tag{23.6}
\end{equation*}
$$

Using Eqs. (23.4) and (23.6), the energy $E\left(A l, 3 s p^{3}\right)$ of the outer electron of the $A l 3 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(A l, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{12}\right)^{3}}=-8.87700 \mathrm{eV}+0.04070 \mathrm{eV}=-8.83630 \mathrm{eV} \tag{23.7}
\end{equation*}
$$

Next, consider the formation of the $A l-H$-bond MO of organoaluminum hydrides wherein each aluminum atom has an $A l 3 s p^{3}$ electron with an energy given by Eq. (23.7). The total energy of the state of each aluminum atom is given by the sum over the three electrons. The sum $E_{T}\left(A l_{\text {organoal }} 3 s p^{3}\right)$ of energies of $A l 3 s p^{3}$ (Eq. (23.7)), $A l^{+}$, and $A l^{2+}$ is:

$$
\begin{align*}
E_{T}\left(A l_{\text {organoAl }} 3 s p^{3}\right) & =-\left(28.44765 \mathrm{eV}+18.82856 \mathrm{eV}+E\left(A l, 3 s p^{3}\right)\right)  \tag{23.8}\\
& =-(28.44765 \mathrm{eV}+18.82856 \mathrm{eV}+8.83630 \mathrm{eV})=-56.11251 \mathrm{eV}
\end{align*}
$$

where $E\left(A l, 3 s p^{3}\right)$ is the sum of the energy of $A l,-5.98577 \mathrm{eV}$, and the hybridization energy.
Each $A l-H$-bond MO of each functional group $A l H_{n=1,2,3}$ forms with the sharing of electrons between each $A l 3 s p^{3} \mathrm{HO}$ and each $H 1 s \mathrm{AO}$. As in the case of $\mathrm{C}-H$, the $H_{2}$-type ellipsoidal MO comprises $75 \%$ of the $\mathrm{Al}-H$-bond MO according to Eq. (13.429). Furthermore, the donation of electron density from each $A l 3 s p^{3} \mathrm{HO}$ to each $\mathrm{Al}-\mathrm{H}$-bond MO permits the participating orbital to decrease in size and energy. As shown below, the aluminum HOs have spin and orbital angular momentum terms in the force balance which determines the geometrical parameters of the $\sigma$ MO. The angular momentum term requires that each $A l-H$-bond MO be treated independently in terms of the charge donation. In order to further satisfy the potential, kinetic, and orbital energy relationships, each $A l 3 s p^{3} \mathrm{HO}$ donates an excess of $25 \%$ of its electron density to each $A l-H$-bond MO to form an energy minimum. By considering this electron redistribution in the organoaluminum hydride molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{\text {organoAlH } 3 s p^{3}}$ of the $A l 3 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$
\begin{equation*}
r_{\text {organoAlH } 3 \text { sp }}=\left(\sum_{n=10}^{12}(Z-n)-0.25\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 56.11251 \mathrm{eV})}=\frac{5.75 e^{2}}{8 \pi \varepsilon_{0}(e 56.11251 \mathrm{eV})}=1.39422 a_{0} \tag{23.9}
\end{equation*}
$$

Using Eqs. (15.19) and (23.9), the Coulombic energy $E_{\text {Coulomb }}\left(A l_{\text {organoAlH }}, 3 s p^{3}\right)$ of the outer electron of the $A l 3 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(A l_{\text {organoAlH }}, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {organoAlH } 3 \text { sp }}{ }^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.39422 a_{0}}=-9.75870 \mathrm{eV} \tag{23.10}
\end{equation*}
$$

During hybridization, the spin-paired $3 s$ electrons are promoted to the $A l 3 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (23.6). Using Eqs. (23.6) and (23.10), the energy $E\left(A l_{\text {organoAlH }}, 3 s p^{3}\right)$ of the outer electron of the $A l 3 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(A l_{\text {organoAlH }}, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{12}\right)^{3}}=-9.75870 \mathrm{eV}+0.04070 \mathrm{eV}=-9.71800 \mathrm{eV} \tag{23.11}
\end{equation*}
$$

Thus, $E_{T}\left(A l-H, 3 s p^{3}\right)$, the energy change of each $A l 3 s p^{3}$ shell with the formation of the $A l-H$-bond MO is given by the difference between Eq. (23.11) and Eq. (23.7):

$$
\begin{equation*}
E_{T}\left(A l-H, 3 s p^{3}\right)=E\left(A l_{\text {organoAlH }}, 3 s p^{3}\right)-E\left(A l, 3 s p^{3}\right)=-9.71800 \mathrm{eV}-(-8.83630 \mathrm{eV})=-0.88170 \mathrm{eV} \tag{23.12}
\end{equation*}
$$

The MO semimajor axis of the $A l-H$ functional group of organoaluminum hydrides is determined from the force balance equation of the centrifugal, Coulombic, and magnetic forces as given in the Polyatomic Molecular Ions and Molecules section and the More Polyatomic Molecules and Hydrocarbons section. The distance from the origin of the $H_{2}$-type-ellipsoidalMO to each focus $c^{\prime}$, the internuclear distance $2 c^{\prime}$, and the length of the semiminor axis of the prolate spheroidal $H_{2}$-type MO $b=c$ are solved from the semimajor axis $a$. Then, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117).

The force balance of the centrifugal force equated to the Coulombic and magnetic forces is solved for the length of the semimajor axis. The Coulombic force on the pairing electron of the MO is:

$$
\begin{equation*}
\mathbf{F}_{\text {Coulomb }}=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D \mathbf{i}_{\xi} \tag{23.13}
\end{equation*}
$$

The spin pairing force is

$$
\begin{equation*}
\mathbf{F}_{\text {spin-pairing }}=\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{23.14}
\end{equation*}
$$

The diamagnetic force is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO1 }}=-\frac{n_{e} \hbar^{2}}{4 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{23.15}
\end{equation*}
$$

where $n_{e}$ is the total number of electrons that interact with the binding $\sigma$-MO electron. The diamagnetic force $\mathbf{F}_{\text {diamagneticмоz }}$ on the pairing electron of the $\sigma \mathrm{MO}$ is given by the sum of the contributions over the components of angular momentum:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO2 }}=-\sum_{i, j} \frac{\left|L_{i}\right| \hbar}{Z_{j} 2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{23.16}
\end{equation*}
$$

where $|L|$ is the magnitude of the angular momentum of each atom at a focus that is the source of the diamagnetism at the $\sigma$ MO. The centrifugal force is:

$$
\begin{equation*}
\mathbf{F}_{\text {centrifugalMO }}=-\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{23.17}
\end{equation*}
$$

The force balance equation for the $\sigma$-MO of the $A l-H$-bond MO is the same as that of the $S i-H$ except that $Z=13$ and there are three spin-unpaired electron in occupied orbitals rather than four, and the orbital with $\ell, m_{\ell}$ angular momentum quantum numbers of $(1,1)$ is unoccupied. With $n_{e}=2$ and $|L|=3 \sqrt{\frac{3}{4}} \hbar$ and $|L|=3 \sqrt{\frac{3}{4}} \hbar$ corresponding to the spin and orbital angular momentum of the three occupied HOs of the $A l 3 s p^{3}$ shell, the force balance equation is:

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(1+\frac{6 \sqrt{\frac{3}{4}}}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{23.18}\\
& a=\left(2+\frac{6 \sqrt{\frac{3}{4}}}{Z}\right) a_{0} \tag{23.19}
\end{align*}
$$

With $Z=13$, the semimajor axis of the $A l-H$-bond MO is:

$$
\begin{equation*}
a=2.39970 a_{0} \tag{23.20}
\end{equation*}
$$

Using the semimajor axis, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.127) in the same manner as the organic functional groups given in the Organic Molecular Functional Groups and Molecules section. For the $\mathrm{Al}-H$ functional group, $c_{1}$ is one and $C_{1}=0.75$ based on the orbital composition as in the case of the $C-H$-bond MO. In organoaluminum hydrides, the energy of aluminum is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{2}$ in Eqs. (15.51) and (15.61) is also one, and the energy matching condition is determined by the $C_{2}$ parameter. Then, the hybridization factor for the $\mathrm{Al}-\mathrm{H}$-bond MO is given by the ratio of 8.87700 eV , the magnitude of $E_{\text {Coulomb }}\left(A l_{\text {organoAlH }}, 3 s p^{3}\right)$ (Eq. (23.4)), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ (Eq. (1.264)):

$$
\begin{equation*}
C_{2}\left(\text { organoAlH } 3 \mathrm{sp}^{3} \mathrm{HO}\right)=\frac{8.87700 \mathrm{eV}}{13.605804 \mathrm{eV}}=0.65244 \tag{23.21}
\end{equation*}
$$

Since the energy of the MO is matched to that of the $A l 3 s p^{3} \mathrm{HO}, E(A O / H O)$ in Eqs. (15.51) and (15.61) is $E\left(A l, 3 s p^{3}\right)$ given by Eq. (23.7), and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -0.88170 eV corresponding to the independent single-bond charge
contribution (Eq. (23.12)). The energies $E_{D}\left(A l H_{n=1,2}\right)$ of the functional groups $A l H_{n=1,2}$ of organoaluminum hydride molecules are each given by the corresponding integer $n$ times that of $A l-H$ :

$$
\begin{equation*}
E_{D}\left(A l H_{n=1,2}\right)=n E_{D}(A l H) \tag{23.22}
\end{equation*}
$$

The branched-chain organoaluminum hydrides, $\mathrm{R}_{n} \mathrm{AlH}_{3-n}$, comprise at least a terminal methyl group $\left(\mathrm{CH}_{3}\right)$ and at least one Al bound by a carbon-aluminum single bond comprising a $\mathrm{C}-\mathrm{Al}$ group, and may comprise methylene ( $\mathrm{CH}_{2}$ ), methylyne ( CH ), $\mathrm{C}-\mathrm{C}$, and $A l H_{n=1,2}$ functional groups. The methyl and methylene functional groups are equivalent to those of straightchain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. These groups in branched-chain organoaluminum hydrides are equivalent to those in branched-chain alkanes.

For the $C-A l$ functional group, hybridization of the $2 s$ and $2 p$ AOs of each $C$ and the $3 s$ and $3 p$ AOs of $A l$ to form single $2 s p^{3}$ and $3 s p^{3}$ shells, respectively, forms an energy minimum, and the sharing of electrons between the $C 2 s p^{3}$ and $A l 3 s p^{3}$ HOs to form a MO permits each participating orbital to decrease in radius and energy. Furthermore, the energy of aluminum is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, in organoaluminum hydrides, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the Al HO has an energy of $E\left(A l, 3 s p^{3}\right)=-8.83630 \mathrm{eV}$. To meet the equipotential, minimum-energy condition of the union of the $A l 3 s p^{3}$ and $C 2 s p^{3} \mathrm{HOs}, c_{2}$ and $C_{2}$ of Eqs. (15.2-15.5), (15.51), and (15.61) for the $\mathrm{Al}-\mathrm{C}$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{align*}
C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Al3sp}^{3} \mathrm{HO}\right) & =c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Al} 3 s p^{3} \mathrm{HO}\right) \\
& =\frac{E\left(A l, 3 s p^{3}\right)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-8.83630 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.55410 \tag{23.23}
\end{align*}
$$

The energy of the $C-A l$-bond MO is the sum of the component energies of the $H_{2}$-type ellipsoidal MO given in Eq. (15.51). Since the energy of the MO is matched to that of the $A l 3 s p^{3} \mathrm{HO}, E(A O / H O)$ in Eqs. (15.51) and (15.61) is $E\left(A l, 3 s p^{3}\right)$ given by Eq. (23.7). Since the $C 2 s p^{3}$ HOs have four electrons with a corresponding total field of ten in Eq. (15.13); whereas, the $A l 3 s p^{3}$ HOs have three electrons with a corresponding total field of six, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -0.72457 eV corresponding to the single-bond contributions of carbon (Eq. (14.151)). $\Delta E_{H_{2} M O}(A O / H O)=E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ in order to match the energies of the carbon and aluminum HOs.

## BRIDGING BONDS OF ORGANOALUMINUM HYDRIDES ( $A l-H-A l$ AND $A l-C-A l$ )

As given in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section, the Organic Molecular Functional Groups and Molecules section, and other sections on bonding in neutral molecules, the molecular chemical bond typically comprises an integer number of paired electrons. One exception given in the Benzene Molecule section and other sections on aromatic molecules such as naphthalene, toluene, chlorobenzene, phenol, aniline, nitrobenzene, benzoic acid, pyridine, pyrimidine, pyrazine, quinoline, isoquinoline, indole, adenine, fullerene, and graphite is that the paired electrons are distributed over a linear combination of bonds such that the bonding between two atoms involves less than an integer multiple of two electrons. In these aromatic cases, three electrons can be assigned to a given bond between two atoms wherein the electrons of the linear combination of bonded atoms are paired and comprise an integer multiple of two.

The $A l 3 s p^{3}$ HOs comprise four orbitals containing three electrons as given by Eq. (23.1). These three occupied orbitals can form three single bonds with other atoms wherein each $A l 3 s p^{3} \mathrm{HO}$ and each orbital from the bonding atom contribute one electron each to the pair of the corresponding bond. However, an alternative bonding is possible that further lowers the energy of the resulting molecule wherein the remaining unoccupied orbital participates in bonding. (Actually an unoccupied orbital has no physical basis. It is only a convenient concept for the bonding electrons in this case additionally having the electron angular momentum state with $\ell, m_{\ell}$ quantum numbers of $(1,1)$ ). In this case the set of two paired electrons are distributed over three atoms and belong to two bonds. Such an electron deficient bonding involving two paired electrons centered on three atoms is called a three-center bond as opposed to the typical single bond called a two-center bond. The designation for a three-center bond involving two $A l 3 s p^{3} \mathrm{HOs}$ and a $H 1 s \mathrm{AO}$ is $A l-H-A l$, and the designation for a three-center bond involving two $A l 3 s p^{3} \mathrm{HOs}$ and a $C 2 s p^{3} \mathrm{HO}$ is $A l-C-A l$.

Each $A l-H-A l$-bond MO and $A l-C-A l$-bond MO comprises the corresponding single bond and forms with further sharing of electrons between each $A l 3 s p^{3} \mathrm{HO}$ and each $H 1 s \mathrm{AO}$ and $C 2 s p^{3} \mathrm{HO}$, respectively. Thus, the geometrical and energy parameters of the three-center bond are equivalent to those of the corresponding two-center bonds except that the bond
energy is increased in the former case since the donation of electron density from the unoccupied $A l 3 s p^{3}$ HO to each $A l-H-A l$-bond MO and $A l-C-A l$-bond MO permits the participating orbital to decrease in size and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, the $A l 3 s p^{3} \mathrm{HO}$ donates an additional excess of $25 \%$ of its electron density to form the bridge (three-center-bond MO) to decrease the energy in the multimer. By considering this electron redistribution in the organoaluminum hydride molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{\text {organoAlH } 3 s p^{3}}$ of the $A l 3 s p^{3}$ shell calculated from the Coulombic energy, the Coulombic energy $E_{\text {Coulomb }}\left(A l_{\text {organoalH }}, 3 s p^{3}\right)$ of the outer electron of the $A l 3 s p^{3}$ shell, and the energy $E\left(A l_{\text {organoalH }}, 3 s p^{3}\right)$ of the outer electron of the $A l 3 s p^{3}$ shell are given by Eqs. (23.9), (23.10), and (23.11), respectively. Thus, $E_{T}\left(A l-H-A l, 3 s p^{3}\right)$ and $E_{T}\left(A l-C-A l, 3 s p^{3}\right)$, the energy change with the formation of the three-center-bond MO from the corresponding two-centerbond MO and the unoccupied $A l 3 s p^{3} \mathrm{HO}$ is given by Eq. (23.12):

$$
\begin{equation*}
E_{T}\left(A l-H-A l, 3 s p^{3}\right)=E_{T}\left(A l-C-A l, 3 s p^{3}\right)=-0.88170 \mathrm{eV} \tag{23.24}
\end{equation*}
$$

The upper range of the experimental association enthalpy per bridge for both of the reactions.

$$
\begin{equation*}
2 \mathrm{AlH}\left(\mathrm{CH}_{3}\right)_{2} \rightarrow\left[\mathrm{AlH}\left(\mathrm{CH}_{3}\right)_{2}\right]_{2} \tag{23.25}
\end{equation*}
$$

and

$$
\begin{equation*}
2 \mathrm{Al}\left(\mathrm{CH}_{3}\right)_{3} \rightarrow\left[\mathrm{Al}\left(\mathrm{CH}_{3}\right)_{3}\right]_{2} \tag{23.26}
\end{equation*}
$$

is [2]

$$
\begin{equation*}
E_{T}\left(A l-H-A l, 3 s p^{3}\right)=E_{T}\left(A l-C-A l, 3 s p^{3}\right)=-0.867 \mathrm{eV} \tag{23.27}
\end{equation*}
$$

which agrees with Eq. (23.24) very well.
The symbols of the functional groups of alkyl organoaluminum hydrides are given in Table 23.1. The geometrical (Eqs. (15.1-15.5), (23.20), and (23.23)) and intercept (Eqs. (15.80-15.87)) parameters of alkyl organoaluminum hydrides are given in Tables 23.2 and 23.3, respectively. Since the energy of the $A l 3 s p^{3} \mathrm{HO}$ is matched to that of the $C 2 s p^{3} \mathrm{HO}$, the radius $r_{\text {mol2sp3 }}$ of the $A l 3 s p^{3} \mathrm{HO}$ of the aluminum atom and the $C 2 s p^{3} \mathrm{HO}$ of the carbon atom of a given $C-A l$-bond MO are calculated after Eq. (15.32) by considering $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$, the total energy donation to all bonds with which each atom participates in bonding. In the case that the MO does not intercept the Al HO due to the reduction of the radius from the donation of $\mathrm{Al} 3 s p^{3}$ HO charge to additional MO's, the energy of each MO is energy matched as a linear sum to the Al HO by contacting it through the bisector current of the intersecting MOs as described in the Methane Molecule ( $\mathrm{CH}_{4}$ ) section. The energy (Eq. (15.61), (23.4), (23.7), and (23.21-23.23)) parameters of alkyl organoaluminum hydrides are given in Table 23.5. The total energy of each alkyl aluminum hydride given in Table 23.5 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 23.4 corresponding to functional-group composition of the molecule. $E_{\text {mag }}$ of Table 23.4 is given by Eqs. (15.15) and (23.3). The bond angle parameters of organoaluminum hydrides determined using Eqs. (15.88-15.117) are given in Table 23.6. The charge-density in trimethyl aluminum is shown in Figure 23.1.

Figure 23.1. Trimethylaluminum. Color scale, translucent view of the charge-density of $\left(\mathrm{H}_{3} \mathrm{C}\right)_{3} \mathrm{Al}$ comprising the linear combination of three sets of three $C-H$-bond MOs and three $C-A l$-bond MOs with the $A l_{\text {ogranotl }} 3 s p^{3}$ HOs and $C 2 s p^{3}$ HOs shown transparently. Each $C-A l$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging $C 2 s p^{3}$ and $A l 3 s p^{3}$ HOs. For each $C-H$ and $C-A l$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C 2 s p^{3}$ HO shell with radius $0.89582 a_{0}$ (Eq. (15.32)) or $A l 3 s p^{3} \mathrm{HO}$, the $A l 3 s p^{3} \mathrm{HO}$ shell with radius $0.85503 a_{0}$ (Eq. (15.32)), inner $A l 1 s$, $A l 2 s$, and $A l 2 p$ shells with radii of $A l l s=0.07778 a_{0}$ (Eq. (10.51)), $A l 2 s=0.33923 a_{0}$ (Eq. (10.62)), and $A l 2 p=0.45620 a_{0}$ (Eq. (10.212)), respectively, and the nuclei (red, not to scale), are shown.

$0 \square 1 \mathrm{e} / \AA^{2}$

Table 23.1. The symbols of the functional groups of organoaluminum hydrides.

| Functional Group | Group Symbol |
| :---: | :---: |
| AlH group of $A l H_{n=1,2}$ | $A l-H$ |
| AlHAl (bridged H) | $A l-H-A l$ |

## TRANSITION METAL ORGANOMETALLIC AND COORDINATE BOND

The transition-metal atoms fill the $3 d$ orbitals in the series $S c$ to $Z n$. The $4 s$ orbitals are filled except in the cases of $C r$ and $C u$ wherein one $4 s$ electron occupies a $3 d$ orbital to achieve a half-filled and filled $3 d$ shell, respectively. Experimentally the transition-metal elements ionize successively from the $4 s$ shell to the $3 d$ shell [12]. Thus, bonding in the transition metals involves the hybridization of the $3 d$ and $4 s$ electrons to form the corresponding number of $3 d 4 s$ HOs except for Cu and Zn which each have a filled inner $3 d$ shell and one and two outer $4 s$ electrons, respectively. Cu may form a single bond involving the $4 s$ electron or the $3 d$ and $4 s$ shells may hybridize to form multiple bonds with one or more ligands. The $4 s$ shell of Zn hybridizes to form two $4 s \mathrm{HOs}$ that provide for two possible bonds, typically two metal-alkyl bonds.

For organometallic and coordinate compounds comprised of carbon, the geometrical and energy equations are given in the Derivation of the General Geometrical and Energy Equations of Organic Chemistry section. For metal-ligand bonds other than to carbon, the force balance equation is that developed in the Force Balance of the $\sigma$ MO of the Carbon Nitride Radical section wherein the diamagnetic force terms include orbital and spin angular momentum contributions. The electrons of the $3 d 4 s$ HOs may pair such that the binding energy of the HO is increased. The hybridization factor accordingly changes which effects the bond distances and energies. The diamagnetic terms of the force balance equations of the electrons of the MOs formed between the $3 d 4 s \mathrm{HOs}$ and the AOs of the ligands also changes depending on whether the nonbonding HOs are occupied by paired or unpaired electrons. The orbital and spin angular momentum of the HOs and MOs is then determined by the state that achieves a minimum energy including that corresponding to the donation of electron charge from the HOs and AOs to the MOs. Historically, according to crystal field theory and molecular orbital theory [13] the possibility of a bonding metal atom achieving a so called "high-spin" or "low-spin" state having unpaired electrons occupying higher-energy orbitals versus paired electrons occupying lower-energy orbitals was due to the strength of the ligand crystal field or the interaction between metal orbitals and the ligands, respectively. Excited-state spectral data recorded on transition-metal organometallic and coordinate compounds has been misinterpreted. Excitation of an unpaired electron in a $3 d 4 s \mathrm{HO}$ to a $3 d 4 s$ paired state is equivalent to an excitation of the molecule to a higher energy MO since the MOs change energy due to the corresponding change in the hybridization factor and diamagnetic force balance terms. But, levels misidentified as crystal field levels do not exist in the absence of excitation by a photon.

The parameters of the $3 d 4 s$ HOs are determined using Eqs. (15.12-15.21). For transition metal atoms with electron configuration $3 d^{n} 4 s^{2}$, the spin-paired $4 s$ electrons are promoted to the $3 d 4 s$ shell during hybridization as unpaired electrons. Also, for $n>5$ the electrons of the $3 d$ shell are spin-paired and these electrons are promoted to the $3 d 4 s$ shell during hybridization as unpaired electrons. The energy for each promotion is the magnetic energy given by Eq. (15.15) at the initial radius of the $4 s$ electrons and the paired $3 d$ electrons determined using Eq. (10.102) with the corresponding nuclear charge $Z$ of the metal atom and the number of electrons, $n$, of the corresponding ion with the filled outer shell from which the pairing energy is determined. Typically, the electrons from the $4 s$ and $3 d$ shells successively fill unoccupied HOs until the HO shell is filled with unpaired electrons, then the electrons pair per HO. The magnetic energy of pairing given by Eqs. (15.13) and (15.15) is added to $E_{\text {Coulomb }}($ atom, $3 d 4 s)$ the for each pair. Thus, after Eq. (15.16), the energy $E($ atom, $3 d 4 s)$ of the outer electron of the atom $3 d 4 s$ shell is given by the sum of $E_{\text {Coulomb }}($ atom, $3 d 4 s)$ and $E$ (magnetic):

$$
\begin{equation*}
E(\text { atom }, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{4 s}^{3}}+\sum_{3 d \text { pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d}^{3}}-\sum_{H O \text { pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d 4 s}^{3}} \tag{23.28}
\end{equation*}
$$

The sharing of electrons between the metal $3 d 4 s$ HOs and the ligand AOs or HOs to form a $M-L$-bond MO ( $L$ not $C$ ) permits each participating hybridized or atomic orbital to decrease in radius and energy. Due to the low binding energy of the metal atom and the high electronegativity of the ligand, an energy minimum is achieved while further satisfying the potential, kinetic, and orbital energy relationships, each metal $3 d 4 s \mathrm{HO}$ donates an excess of an electron per bond of its electron density to the $M-L$-bond MO. In each case, the radius of the hybridized shell is calculated from the Coulombic energy equation by considering that the central field decreases by an integer for each successive electron of the shell and the total energy of the shell is equal to the total Coulombic energy of the initial AO electrons plus the hybridization energy. After Eq. (15.17), the total energy $E_{T}$ ( mol.atom, $3 d 4 s$ ) of the HO electrons is given by the sum of energies of successive ions of the atom over the $n$ electrons comprising the total electrons of the initial AO shell and the hybridization energy:

$$
\begin{equation*}
E_{T}(\text { mol.atom, } 3 d 4 s)=E(\text { atom, } 3 d 4 s)-\sum_{m=2}^{n} I P_{m} \tag{23.29}
\end{equation*}
$$

where $I P_{m}$ is the $m$ th ionization energy (positive) of the atom and the sum of $-I P_{1}$ plus the hybridization energy is $E($ atom, $3 d 4 s)$. Thus, the radius $r_{3 d 4 s}$ of the hybridized shell due to its donation of a total charge $-Q e$ to the corresponding MO is given by is given by:

$$
\begin{equation*}
r_{3 d 4 s}=\left(\sum_{q=Z-n}^{Z-1}(Z-q)-Q\right) \frac{-e^{2}}{8 \pi \varepsilon_{0} E_{T}(\text { mol.atom }, 3 d 4 s)}=\left(\sum_{q=Z-n}^{Z-1}(Z-q)-s(0.25)\right) \frac{-e^{2}}{8 \pi \varepsilon_{0} E_{T}(\text { mol.atom }, 3 d 4 s)} \tag{23.30}
\end{equation*}
$$

where $-e$ is the fundamental electron charge, $s=1,2,3$ for a single, double, and triple bond, respectively, and $s=4$ for typical coordinate and organometallic compounds wherein $L$ is not carbon. The Coulombic energy $E_{\text {Coulomb }}($ mol.atom, $3 d 4 s)$ of the outer electron of the atom $3 d 4 s$ shell is given by

$$
\begin{equation*}
E_{\text {Coulomb }}(\text { mol.atom, } 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}} \tag{23.31}
\end{equation*}
$$

In the case that during hybridization the metal spin-paired $4 s \mathrm{AO}$ electrons are unpaired to contribute electrons to the $3 d 4 s \mathrm{HO}$, the energy change for the promotion to the unpaired state is the magnetic energy $E$ (magnetic) at the initial radius $r$ of the AO electron given by Eq. (15.15). In addition in the case that the $3 d 4 s$ HO electrons are paired, the corresponding magnetic energy is added. Then, the energy $E$ ( mol.atom, $3 d 4 s$ ) of the outer electron of the atom $3 d 4 s$ shell is given by the sum of $E_{\text {Coulomb }}($ mol.atom, $3 d 4 s)$ and $E$ (magnetic) :

$$
\begin{equation*}
E(\text { mol.atom, } 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{4 s}^{3}}-\sum_{H O \text { pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d 4 s}^{3}} \tag{23.32}
\end{equation*}
$$

$E_{T}($ atom-atom, $3 d 4 s)$, the energy change of each atom $m s p^{3}$ shell with the formation of the atom-atom-bond MO is given by the difference between $E$ (mol.atom, $3 d 4 s$ ) and $E($ atom, $3 d 4 s)$ :

$$
\begin{equation*}
E_{T}(\text { atom }- \text { atom }, 3 d 4 s)=E(\text { mol.atom }, 3 d 4 s)-E(\text { atom }, 3 d 4 s) \tag{23.33}
\end{equation*}
$$

Any unpaired electrons of ligands typically pair with unpaired HO electrons of the metal. In the case that no such electrons of the metal are available, the ligand electrons pair and form a bond with an unpaired metal HO when available. An unoccupied HO may form by the pairing of the corresponding HO electrons to form an energy minimum due to the effect on the bond parameters such as the diamagnetic force term, hybridization factor, and the $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} \cdot A O\right)$ term. In the case of carbonyls, the two unpaired $C s p^{3}$ HO electrons on each carbonyl pair with any unpaired electrons of the metal HOs. Any excess carbonyl electrons pair in the formation of the corresponding MO and any remaining metal HO electrons pair where possible. In the latter case, the energy of the HO for the determination of the hybridization factor and other bonding parameters in Eqs. (15.51) and (15.65) is given by the Coulombic energy plus the pairing energy.

The force balance of the centrifugal force equated to the Coulombic and magnetic forces is solved for the length of the semimajor axis. The Coulombic force on the pairing electron of the MO is:

$$
\begin{equation*}
\mathbf{F}_{\text {Coulomb }}=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D \mathbf{i}_{\xi} \tag{23.34}
\end{equation*}
$$

The spin pairing force is

$$
\begin{equation*}
\mathbf{F}_{\text {spin-pairing }}=\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{23.35}
\end{equation*}
$$

The diamagnetic force is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO1 }}=-\frac{n_{e} \hbar^{2}}{4 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{23.36}
\end{equation*}
$$

where $n_{e}$ is the total number of electrons that interact with the binding $\sigma$-MO electron. The diamagnetic force $\mathbf{F}_{\text {diamagneticMO2 }}$ on the pairing electron of the $\sigma$ MO is given by the sum of the contributions over the components of angular momentum:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO2 }}=-\sum_{i} \frac{\left|L_{i}\right| \hbar}{Z 2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{23.37}
\end{equation*}
$$

where $\left|L_{i}\right|$ is the magnitude of the angular momentum component of the metal atom at a focus that is the source of the diamagnetism at the $\sigma$-MO. The centrifugal force is:

$$
\begin{equation*}
\mathbf{F}_{\text {centrifugalMO }}=-\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{23.38}
\end{equation*}
$$

The general force balance equation for the $\sigma$-MO of the metal (M) to ligand (L) $M-L$-bond MO in terms of $n_{e}$ and $\left|L_{i}\right|$ corresponding to the orbital and spin angular momentum terms of the $3 d 4 s \mathrm{HO}$ shell is:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(\frac{n_{e}}{2}+\sum_{i} \frac{\left|L_{i}\right|}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \tag{23.39}
\end{equation*}
$$

Having a solution for the semimajor axis $a$ of:

$$
\begin{equation*}
a=\left(1+\frac{n_{e}}{2}+\sum_{i} \frac{\left|L_{i}\right|}{Z}\right) a_{0} \tag{23.40}
\end{equation*}
$$

In term of the total angular momentum $L$, the semimajor axis $a$ is:

$$
\begin{equation*}
a=\left(1+\frac{n_{e}}{2}+\frac{L}{Z}\right) a_{0} \tag{23.41}
\end{equation*}
$$

Using the semimajor axis, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in the Organic Molecular Functional Groups and Molecules section.

Bond angles in organometallic and coordinate compounds are determined using the standard Eqs. (15.70-15.79) and (15.88-15.117) with the appropriate $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ for energy matching with the $B-C$ terminal bond of the corresponding angle $\angle B A C$. For bond angles in general, if the groups can be maximally displaced in terms of steric interactions and magnitude of the residual $E_{T}$ term is less that the steric energy, then the geometry that minimizes the steric interactions is the lowest energy. Steric-energy minimizing geometries include tetrahedral $\left(T_{d}\right)$ and octahedral symmetry $\left(O_{h}\right)$.

## SCANDIUM FUNCTIONAL GROUPS AND MOLECULES

The electron configuration of scandium is $[A r] 4 s^{2} 3 d$ having the corresponding term ${ }^{2} D_{3 / 2}$. The total energy of the state is given by the sum over the three electrons. The sum $E_{T}(S c, 3 d 4 s)$ of experimental energies [1] of $S c, S c^{+}$, and $S c^{2+}$ is:

$$
\begin{equation*}
E_{T}(S c, 3 d 4 s)=-(24.75666 \mathrm{eV}+12.79977 \mathrm{eV}+6.56149 \mathrm{eV})=-44.11792 \mathrm{eV} \tag{23.42}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 d 4 s}$ of the $S c 3 d 4 s$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{3 d 4 s}=\sum_{n=18}^{20} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 44.11792 \mathrm{eV})}=\frac{6 e^{2}}{8 \pi \varepsilon_{0}(e 44.11792 \mathrm{eV})}=1.85038 a_{0} \tag{23.43}
\end{equation*}
$$

where $Z=21$ for scandium. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}(S c, 3 d 4 s)$ of the outer electron of the $S c 3 d 4 s$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}(S c, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.85038 a_{0}}=-7.35299 \mathrm{eV} \tag{23.44}
\end{equation*}
$$

During hybridization, the spin-paired $4 s$ electrons are promoted to the $\operatorname{Sc} 3 d 4 s$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (15.15) at the initial radius of the $4 s$ electrons. From Eq. (10.102) with $Z=21$ and $n=21$, the radius $r_{21}$ of the $S c 4 s$ shell is:

$$
\begin{equation*}
r_{21}=2.07358 a_{0} \tag{23.45}
\end{equation*}
$$

Using Eqs. (15.15) and (23.45), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{21}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(2.07358 a_{0}\right)^{3}}=0.01283 \mathrm{eV} \tag{23.46}
\end{equation*}
$$

Using Eqs. (23.44) and (23.46), the energy $E(S c, 3 d 4 s)$ of the outer electron of the $S c 3 d 4 s$ shell is:

$$
\begin{equation*}
E(S c, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{21}\right)^{3}}=-7.352987 \mathrm{eV}+0.01283 \mathrm{eV}=-7.34015 \mathrm{eV} \tag{23.47}
\end{equation*}
$$

Next, consider the formation of the $S c-L$-bond MO wherein each scandium atom has an $S c 3 d 4 s$ electron with an energy given by Eq. (23.47). The total energy of the state of each scandium atom is given by the sum over the three electrons. The sum $E_{T}\left(S c_{S c-L} 3 d 4 s\right)$ of energies of $S c 3 d 4 s$ (Eq. (23.47)), $S c^{+}$, and $S c^{2+}$ is:

$$
\begin{align*}
E_{T}\left(S c_{S c-L} 3 d 4 s\right) & =-(24.75666 \mathrm{eV}+12.79977 \mathrm{eV}+E(S c, 3 \mathrm{~d} 4 \mathrm{~s}))  \tag{23.48}\\
& =-(24.75666 \mathrm{eV}+12.79977 \mathrm{eV}+7.34015 \mathrm{eV})=-44.89658 \mathrm{eV}
\end{align*}
$$

where $E(S c, 3 d 4 s)$ is the sum of the energy of $S c,-6.56149 \mathrm{eV}$, and the hybridization energy.
The scandium HO donates an electron to each MO. Using Eq. (23.30), the radius $r_{3 d 4 s}$ of the $S c 3 d 4 s$ shell calculated from the Coulombic energy is:

$$
\begin{equation*}
r_{S c-L 3 d 4 s}=\left(\sum_{n=18}^{20}(Z-n)-1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 44.89658 \mathrm{eV})}=\frac{5 e^{2}}{8 \pi \varepsilon_{0}(e 44.89658 \mathrm{eV})}=1.51524 a_{0} \tag{23.49}
\end{equation*}
$$

Using Eqs. (15.19) and (23.49), the Coulombic energy $E_{\text {Coulomb }}\left(S c_{S c-L}, 3 d 4 s\right)$ of the outer electron of the $S c 3 d 4 s$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(S c_{S c-L}, 3 d 4 s\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{S c-L 3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.51524 a_{0}}=-8.97932 \mathrm{eV} \tag{23.50}
\end{equation*}
$$

The only magnetic energy term is that for the unpairing of the $4 s$ electrons given by Eq. (23.46). Using Eqs. (23.32), (23.46), and (23.50), the energy $E\left(S c_{S c-L}, 3 d 4 s\right)$ of the outer electron of the $S c 3 d 4 s$ shell is:

$$
\begin{equation*}
E\left(S c_{S c-L}, 3 d 4 s\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{S c-L 3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{21}\right)^{3}}=-8.97932 \mathrm{eV}+0.01283 \mathrm{eV}=-8.96648 \mathrm{eV} \tag{23.51}
\end{equation*}
$$

Thus, $E_{T}(S c-L, 3 d 4 s)$, the energy change of each $S c 3 d 4 s$ shell with the formation of the $S c-L$-bond MO is given by the difference between Eq. (23.51) and Eq. (23.47).

$$
\begin{equation*}
E_{T}(S c-L, 3 d 4 s)=E\left(S c_{S c-L}, 3 d 4 s\right)-E(S c, 3 d 4 s)=-8.96648 \mathrm{eV}-(-7.34015 \mathrm{eV})=-1.62633 \mathrm{eV} \tag{23.52}
\end{equation*}
$$

The semimajor axis $a$ solution given by Eq. (23.41) of the force balance equation, Eq. (23.39), for the $\sigma$-MO of the $S c-L$-bond MO of $S c L_{n}$ is given in Table 23.8 with the force-equation parameters $Z=21, n_{e}$, and $L$ corresponding to the orbital and spin angular momentum terms of the $3 d 4 s$ HO shell.

For the $S c-L$ functional groups, hybridization of the $4 s$ and $3 d$ AOs of $S c$ to form a single $3 d 4 s$ shell forms an energy minimum, and the sharing of electrons between the $S c 3 d 4 s \mathrm{HO}$ and $L \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. The $F \mathrm{AO}$ has an energy of $E(F)=-17.42282 \mathrm{eV}$, the Cl AO has an energy of $E(C l)=-12.96764 \mathrm{eV}$, the $O$ AO has an energy of $E(O)=-13.61805 \mathrm{eV}$, and the $S c 3 d 4 s$ HOs have an energy of $E(S c, 3 d 4 s)=-7.34015 \mathrm{eV}$ (Eq. (23.47)). To meet the equipotential condition of the union of the $S c-L H_{2}$-type-ellipsoidalMO with these orbitals, the hybridization factor(s), at least one of $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $S c-L$-bond MO given by Eq. (15.77) is:

$$
\begin{align*}
& c_{2}(F A O \text { to } S c 3 d 4 s H O)=C_{2}(F A O \text { to } S c 3 d 4 s H O)=\frac{E(S c, 3 d 4 s)}{E(F A O)}=\frac{-7.34015 \mathrm{eV}}{-17.42282 \mathrm{eV}}=0.42130  \tag{23.53}\\
& c_{2}(C l A O \text { to } S c 3 d 4 \mathrm{sHO})=C_{2}(C l A O \text { to } S c 3 d 4 \mathrm{sHO})=\frac{E(S c, 3 d 4 s)}{E(C l A O)}=\frac{-7.34015 \mathrm{eV}}{-12.96764 \mathrm{eV}}=0.56604  \tag{23.54}\\
& c_{2}(O \text { to } S c 3 d 4 \mathrm{sHO})=\frac{E(S c, 3 d 4 s)}{E(O)}=\frac{-7.34015 \mathrm{eV}}{-13.61805 \mathrm{eV}}=0.53900 \tag{23.55}
\end{align*}
$$

Since the energy of the MO is matched to that of the $S c 3 d 4 s \mathrm{HO}, E(A O / H O)$ in Eq. (15.61) is $E(S c, 3 d 4 s)$ given by Eq. (23.47) and twice this value for double bonds. $\quad E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $S c-L$-bond MO is determined by considering that the bond involves an electron transfer from the scandium atom to the ligand atom to form partial ionic character in the bond as in the case of the zwitterions such as $H_{2} B^{+}-F^{-}$given in the Halido Boranes section. $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)$ is -3.25266 eV , two times the energy of Eq. (23.52) for single bonds, and -6.50532 eV , four times the energy of Eq. (23.52) for double bonds.

The symbols of the functional groups of scandium coordinate compounds are given in Table 23.7. The geometrical (Eqs. (15.1-15.5) and (23.41)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of scandium coordinate compounds are given in Tables $23.8,23.9$, and 23.10 , respectively. The total energy of each scandium coordinate compound given in Table 23.11 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 23.10 corresponding to functional-group composition of the compound. The charge-densities of exemplary scandium coordinate compound, scandium trifluoride comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 23.2.

Figure 23.2. Scandium Trifluoride. Color scale, translucent view of the charge-density of $S c F_{3}$ showing the orbitals of the $S c$ and $F$ atoms at their radii, the ellipsoidal surface of each $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale).

Table 23.7. The symbols of the functional groups of scandium coordinate compounds.

## TITANIUM FUNCTIONAL GROUPS AND MOLECULES

The electron configuration of titanium is $[A r] 4 s^{2} 3 d^{2}$ having the corresponding term ${ }^{3} F_{2}$. The total energy of the state is given by the sum over the four electrons. The sum $E_{T}(T i, 3 d 4 s)$ of experimental energies [1] of $T i, T i^{+}, T i^{2+}$, and $T i^{3+}$ is

$$
\begin{equation*}
E_{T}(T i, 3 d 4 s)=-(43.2672 \mathrm{eV}+27.4917 \mathrm{eV}+13.5755 \mathrm{eV}+6.82812 \mathrm{eV})=-91.16252 \mathrm{eV} \tag{23.56}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 d 4 s}$ of the $T i 3 d 4 s$ shell may be calculated from the Coulombic energy using Eq. (15.13):

$$
\begin{equation*}
r_{3 d 4 s}=\sum_{n=18}^{21} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 91.16252 \mathrm{eV})}=\frac{10 e^{2}}{8 \pi \varepsilon_{0}(e 91.16252 \mathrm{eV})}=1.49248 a_{0} \tag{23.57}
\end{equation*}
$$

where $Z=22$ for titanium. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}(T i, 3 d 4 s)$ of the outer electron of the Ti3d $4 s$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}(T i, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.49248 a_{0}}=-9.11625 \mathrm{eV} \tag{23.58}
\end{equation*}
$$

During hybridization, the spin-paired $4 s$ electrons are promoted to the $T i 3 d 4 s$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (15.15) at the initial radius of the $4 s$ electrons. From Eq. (10.102) with $Z=22$ and $n=22$, the radius $r_{22}$ of the Ti4s shell is:

$$
\begin{equation*}
r_{22}=1.99261 a_{0} \tag{23.59}
\end{equation*}
$$

Using Eqs. (15.15) and (23.59), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{22}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(1.99261 a_{0}\right)^{3}}=0.01446 \mathrm{eV} \tag{23.60}
\end{equation*}
$$

Using Eqs. (23.58) and (23.60), the energy $E(T i, 3 d 4 s)$ of the outer electron of the $T i 3 d 4 s$ shell is:

$$
\begin{equation*}
E(T i, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{22}\right)^{3}}=-9.11625 \mathrm{eV}+0.01446 \mathrm{eV}=-9.10179 \mathrm{eV} \tag{23.61}
\end{equation*}
$$

Next, consider the formation of the $T i-L$-bond MO wherein each titanium atom has a $T i 3 d 4 s$ electron with an energy given by Eq. (23.61). The total energy of the state of each titanium atom is given by the sum over the four electrons. The sum $E_{T}\left(T i_{T i-L} 3 d 4 s\right)$ of energies of $T i 3 d 4 s$ (Eq. (23.61)), $T i^{+}, T i^{2+}$, and $T i^{3+}$ is:

$$
\begin{align*}
E_{T}\left(T i_{T i-L} 3 d 4 s\right) & =-(43.2672 \mathrm{eV}+27.4917 \mathrm{eV}+13.5755 \mathrm{eV}+E(T i, 3 \mathrm{~d} 4 \mathrm{~s})) \\
& =-(43.2672 \mathrm{eV}+27.4917 \mathrm{eV}+13.5755 \mathrm{eV}+9.10179 \mathrm{eV})  \tag{23.62}\\
& =-93.43619 \mathrm{eV}
\end{align*}
$$

where $E(T i, 3 d 4 s)$ is the sum of the energy of $T i,-6.82812 \mathrm{eV}$, and the hybridization energy.
The titanium HO donates an electron to each MO. Using Eq. (23.30), the radius $r_{3 d 4 s}$ of the Ti3d4s shell calculated from the Coulombic energy is:

$$
\begin{equation*}
r_{T i-L 3 d 4 s}=\left(\sum_{n=18}^{21}(Z-n)-1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 93.43619 e V)}=\frac{9 e^{2}}{8 \pi \varepsilon_{0}(e 93.43619 \mathrm{eV})}=1.31054 a_{0} \tag{23.63}
\end{equation*}
$$

Using Eqs. (15.19) and (23.63), the Coulombic energy $E_{\text {Coulomb }}\left(T i_{T i-L}, 3 d 4 s\right)$ of the outer electron of the Ti3d $4 s$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(T i_{T i-L}, 3 d 4 s\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{T i-L 3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.31054 a_{0}}=-10.38180 \mathrm{eV} \tag{23.64}
\end{equation*}
$$

The only magnetic energy term is that for the unpairing of the $4 s$ electrons given by Eq. (23.60). Using Eqs. (23.32), (23.60), and (23.64), the energy $E\left(T i_{T i-L}, 3 d 4 s\right)$ of the outer electron of the $T i 3 d 4 s$ shell is:

$$
\begin{equation*}
E\left(T i_{T i-L}, 3 d 4 s\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{T i-L 3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{22}\right)^{3}}=-10.38180 \mathrm{eV}+0.01446 \mathrm{eV}=-10.36734 \mathrm{eV} \tag{23.65}
\end{equation*}
$$

Thus, $E_{T}(T i-L, 3 d 4 s)$, the energy change of each $T i 3 d 4 s$ shell with the formation of the $T i-L$-bond MO is given by the difference between Eq. (23.65) and Eq. (23.61).

$$
\begin{equation*}
E_{T}(T i-L, 3 d 4 s)=E\left(T i_{T i-L}, 3 d 4 s\right)-E(T i, 3 d 4 s)=-10.36734 \mathrm{eV}-(-9.10179 \mathrm{eV})=-1.26555 \mathrm{eV} \tag{23.66}
\end{equation*}
$$

The semimajor axis $a$ solution given by Eq. (23.41) of the force balance equation, Eq. (23.39), for the $\sigma$-MO of the $T i-L$-bond MO of $T i L_{n}$ is given in Table 23.13 with the force-equation parameters $Z=22, n_{e}$, and $L$ corresponding to the orbital and spin angular momentum terms of the $3 d 4 \mathrm{~s}$ HO shell.

For the $T i-L$ functional groups, hybridization of the $4 s$ and $3 d$ AOs of $T i$ to form a single $3 d 4 s$ shell forms an energy minimum, and the sharing of electrons between the $T i 3 d 4 s \mathrm{HO}$ and $L \mathrm{AO}$ to form a MO permits each participating orbital to
decrease in radius and energy. The $F \mathrm{AO}$ has an energy of $E(F)=-17.42282 \mathrm{eV}$, the Cl AO has an energy of $E(C l)=-12.96764 \mathrm{eV}$, the Br AO has an energy of $E(B r)=-11.8138 \mathrm{eV}$, the $I \mathrm{AO}$ has an energy of $E(I)=-10.45126 \mathrm{eV}$, the $O$ AO has an energy of $E(O)=-13.61805 \mathrm{eV}$, and the Ti3d4s HOs have an energy of $E(T i, 3 d 4 s)=-9.10179 \mathrm{eV}$ (Eq. (23.61)). To meet the equipotential condition of the union of the $T i-L H_{2}$-type-ellipsoidalMO with these orbitals, the hybridization factor(s), at least one of $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $T i-L$-bond MO given by Eq. (15.77) is:

$$
\begin{align*}
& C_{2}(\text { FAO to Ti3d } 4 \mathrm{sHO})=\frac{E(T i, 3 d 4 \mathrm{~s})}{E(F A O)}=\frac{-9.10179 \mathrm{eV}}{-17.42282 \mathrm{eV}}=0.52241  \tag{23.67}\\
& C_{2}(\mathrm{ClAO} \text { to Ti3d } 4 \mathrm{sHO})=\frac{E(T i, 3 d 4 \mathrm{~s})}{E(C l A O)}=\frac{-9.10179 \mathrm{eV}}{-12.96764 \mathrm{eV}}=0.70188  \tag{23.68}\\
& c_{2}(\mathrm{BrAO} \text { to Ti } 3 \mathrm{~d} 4 \mathrm{sHO})=C_{2}(\mathrm{BrAO} \text { to } T i 3 d 4 \mathrm{sHO})=\frac{E(T i, 3 d 4 \mathrm{~s})}{E(B r A O)}=\frac{-9.10179 \mathrm{eV}}{-11.8138 \mathrm{eV}}=0.77044  \tag{23.69}\\
& c_{2}(\mathrm{IAO} \text { to Ti3d } 4 \mathrm{sHO})=C_{2}(I A O \text { to Ti3d } 4 \mathrm{sHO})=\frac{E(T i, 3 d 4 \mathrm{~s})}{E(I A O)}=\frac{-9.10179 \mathrm{eV}}{-10.45126 \mathrm{eV}}=0.87088  \tag{23.70}\\
& c_{2}(O \text { to Ti3d } 4 \mathrm{sHO})=\frac{E(T i, 3 d 4 \mathrm{~s})}{E(O)}=\frac{-9.10179 \mathrm{eV}}{-13.61805 \mathrm{eV}}=0.66836 \tag{23.71}
\end{align*}
$$

Since the energy of the MO is matched to that of the Ti3d $4 s \mathrm{HO}, E(A O / H O)$ in Eq. (15.61) is $E(T i, 3 d 4 s)$ given by Eq. (23.61) and twice this value for double bonds. $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $T i-L$-bond MO is determined by considering that the bond involves an electron transfer from the titanium atom to the ligand atom to form partial ionic character in the bond as in the case of the zwitterions such as $\mathrm{H}_{2} \mathrm{~B}^{+}-\mathrm{F}^{-}$given in the Halido Boranes section. $E_{T}\left(\right.$ atom - atom, msp $\left.{ }^{3} . A O\right)$ is -2.53109 eV , two times the energy of Eq. (23.66).

The symbols of the functional groups of titanium coordinate compounds are given in Table 23.12. The geometrical (Eqs. (15.1-15.5) and (23.41)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of titanium coordinate compound are given in Tables 23.13, 23.14, and 23.15, respectively. The total energy of each titanium coordinate compounds given in Table 23.16 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 23.15 corresponding to functional-group composition of the compound. The bond angle parameters of titanium coordinate compounds determined using Eqs. (15.88-15.117) are given in Table 23.17. The $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)$ term for $\mathrm{TiOCl}_{2}$ was calculated using Eqs. (23.30-23.33) as a linear combination of $s=1$ and $s=2$ for the energies of $E(T i, 3 d 4 s)$ given by Eqs. (23.63-23.66) corresponding to a $\mathrm{Ti}-\mathrm{Cl}$ single bond and a $T i=O$ double bond. The charge-densities of exemplary titanium coordinate compound, titanium tetrafluoride comprising the concentric shells of atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 23.3.

Figure 23.3. Titanium Tetrafluoride. Color scale, translucent view of the charge-density of $T i F_{4}$ showing the orbitals of the Ti and $F$ atoms at their radii, the ellipsoidal surface of each $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale).

## VANADIUM FUNCTIONAL GROUPS AND MOLECULES

The electron configuration of vanadium is $[A r] 4 s^{2} 3 d^{3}$ having the corresponding term ${ }^{4} F_{3 / 2}$. The total energy of the state is given by the sum over the five electrons. The sum $E_{T}(V, 3 d 4 s)$ of experimental energies [1] of $V, V^{+}, V^{2+}, V^{3+}$, and $V^{4+}$ is

$$
\begin{equation*}
E_{T}(V, 3 d 4 s)=-(65.2817 \mathrm{eV}+46.709 \mathrm{eV}+29.311 \mathrm{eV}+14.618 \mathrm{eV}+6.74619 \mathrm{eV})=-162.66589 \mathrm{eV} \tag{23.72}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 d 4 s}$ of the $V 3 d 4 s$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{3 d 4 s}=\sum_{n=18}^{22} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 162.66589 \mathrm{eV})}=\frac{15 e^{2}}{8 \pi \varepsilon_{0}(e 162.66589 \mathrm{eV})}=1.25464 a_{0} \tag{23.73}
\end{equation*}
$$

where $Z=23$ for vanadium. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}(V, 3 d 4 s)$ of the outer electron of the $V 3 d 4 s$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}(V, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.25464 a_{0}}=-10.844393 \mathrm{eV} \tag{23.74}
\end{equation*}
$$

During hybridization, the spin-paired $4 s$ electrons are promoted to the $V 3 d 4 s$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (15.15) at the initial radius of the $4 s$ electrons. From Eq. (10.102) with $Z=23$ and $n=23$, the radius $r_{23}$ of the $V 4 s$ shell is:

$$
\begin{equation*}
r_{23}=2.01681 a_{0} \tag{23.75}
\end{equation*}
$$

Using Eqs. (15.15) and (23.74), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{23}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(2.01681 a_{0}\right)^{3}}=0.01395 \mathrm{eV} \tag{23.76}
\end{equation*}
$$

Using Eqs. (23.73) and (23.75), the energy $E(V, 3 d 4 s)$ of the outer electron of the $V 3 d 4 s$ shell is:

$$
\begin{equation*}
E(V, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{23}\right)^{3}}=-10.844393 \mathrm{eV}+0.01395 \mathrm{eV}=-10.83045 \mathrm{eV} \tag{23.77}
\end{equation*}
$$

Next, consider the formation of the $V-L$-bond MO wherein each vanadium atom has a $V 3 d 4 s$ electron with an energy given by Eq. (23.76). The total energy of the state of each vanadium atom is given by the sum over the five electrons. The sum $E_{T}\left(V_{V-L} 3 d 4 s\right)$ of energies of $V 3 d 4 s$ (Eq. (23.76)), $V^{+}, V^{2+}, V^{3+}$, and $V^{4+}$ is:

$$
\begin{align*}
E_{T}\left(V_{V-L} 3 d 4 s\right) & =-\binom{65.2817 \mathrm{eV}+46.709 \mathrm{eV}+29.311 \mathrm{eV}}{+14.618 \mathrm{eV}+E(V, 3 \mathrm{~d} 4 \mathrm{~s})}=-\binom{65.2817 \mathrm{eV}+46.709 \mathrm{eV}+29.311 \mathrm{eV}}{+14.618 \mathrm{eV}+10.83045}  \tag{23.78}\\
& =-166.75015 \mathrm{eV}
\end{align*}
$$

where $E(V, 3 d 4 s)$ is the sum of the energy of $V,-6.74619 \mathrm{eV}$, and the hybridization energy.
The vanadium HO donates an electron to each MO. Using Eq. (23.30), the radius $r_{3 d 4 s}$ of the $V 3 d 4 s$ shell calculated from the Coulombic energy is:

$$
\begin{equation*}
r_{V-L 3 d 4 s}=\left(\sum_{n=18}^{22}(Z-n)-1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 166.75015 \mathrm{eV})}=\frac{14 e^{2}}{8 \pi \varepsilon_{0}(e 166.75015 \mathrm{eV})}=1.14232 a_{0} \tag{23.79}
\end{equation*}
$$

Using Eqs. (15.19) and (23.78), the Coulombic energy $E_{\text {Coulomb }}\left(V_{V-L}, 3 d 4 s\right)$ of the outer electron of the $V 3 d 4 s$ shell is

$$
\begin{equation*}
E_{\text {Coulomb }}\left(V_{V-L}, 3 d 4 s\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{V-L 3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.14232 a_{0}}=-11.91072 \mathrm{eV} \tag{23.80}
\end{equation*}
$$

The only magnetic energy term is that for the unpairing of the $4 s$ electrons given by Eq. (23.75). Using Eqs. (23.32), (23.73), and (23.79), the energy $E\left(V_{V-L}, 3 d 4 s\right)$ of the outer electron of the $V 3 d 4 s$ shell is:

$$
\begin{equation*}
E\left(V_{V-L}, 3 d 4 s\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{V-L 3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{23}\right)^{3}}=-11.91072 \mathrm{eV}+0.01446 \mathrm{eV}=-11.89678 \mathrm{eV} \tag{23.81}
\end{equation*}
$$

Thus, $E_{T}(V-L, 3 d 4 s)$, the energy change of each $V 3 d 4 s$ shell with the formation of the $V-L$-bond MO is given by the difference between Eq. (23.80) and Eq. (23.76):

$$
\begin{equation*}
E_{T}(V-L, 3 d 4 s)=E\left(V_{V-L}, 3 d 4 s\right)-E(V, 3 d 4 s)=-11.89678 \mathrm{eV}-(-10.83045 \mathrm{eV})=-1.06633 \mathrm{eV} \tag{23.82}
\end{equation*}
$$

The semimajor axis $a$ solution given by Eq. (23.41) of the force balance equation, Eq. (23.39), for the $\sigma$-MO of the $V-L$-bond MO of $V L_{n}$ is given in Table 23.19 with the force-equation parameters $Z=23, n_{e}$, and $L$ corresponding to the orbital and spin angular momentum terms of the $3 d 4 s$ HO shell. The semimajor axis $a$ of carbonyl and organometallic compounds are solved using Eq. (15.51).

For the $V-L$ functional groups, hybridization of the $4 s$ and $3 d$ AOs of $V$ to form a single $3 d 4 s$ shell forms an energy
minimum, and the sharing of electrons between the $V 3 d 4 s \mathrm{HO}$ and $L \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. The $F$ AO has an energy of $E(F)=-17.42282 \mathrm{eV}$, the Cl AO has an energy of $E(C l)=-12.96764 \mathrm{eV}$, the $C_{\text {aryl }} 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C_{\text {aryl }}, 2 s p^{3}\right)=-15.76868 \mathrm{eV}$ (Eq. (14.246)), the $C 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), the $N$ AO has an energy of $E(N)=-14.53414 \mathrm{eV}$, the $O$ AO has an energy of $E(O)=-13.61805 \mathrm{eV}$, and the $V 3 d 4 \mathrm{~s}$ HO has an energy of $E_{\text {Coulomb }}(V, 3 d 4 s)=-10.84439 \mathrm{eV}$ (Eq. (23.75)) and $E(V, 3 d 4 s)=-10.83045 \mathrm{eV}$ (Eq. (23.76)). To meet the equipotential condition of the union of the $V-L H_{2}$-type-ellipsoidalMO with these orbitals, the hybridization factor(s), at least one of $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $V-L$-bond MO given by Eq. (15.77) is:

$$
\begin{align*}
& C_{2}(F A O \text { to } V 3 d 4 s H O)=\frac{E(V, 3 d 4 s)}{E(F A O)}=\frac{-10.83045 \mathrm{eV}}{-17.42282 \mathrm{eV}}=0.62162  \tag{23.83}\\
& C_{2}(C l A O \text { to } V 3 d 4 s H O)=\frac{E(V, 3 d 4 s)}{E(C l A O)}=\frac{-10.83045 \mathrm{eV}}{-12.96764 \mathrm{eV}}=0.83519  \tag{23.84}\\
& C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{V} 3 d 4 \mathrm{sHO}\right)=\frac{E_{\text {Coulomb }}(V, 3 d 4 \mathrm{~s})}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-10.84439 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.68002  \tag{23.85}\\
& c_{2}\left(C_{\text {aryl }} 2 s p^{3} \mathrm{HO} \text { to } \mathrm{V} 3 d 4 \mathrm{sHO}\right)=C_{2}\left(C_{\text {aryl }} 2 s p^{3} \mathrm{HO} \text { to } \mathrm{V} 3 \mathrm{~d} 4 \mathrm{sHO}\right)=\frac{E_{\text {Coulomb }}(\mathrm{V}, 3 \mathrm{~d} 4 \mathrm{~s})}{E\left(C_{\text {aryl }}, 2 s p^{3}\right)}=\frac{-10.84439 \mathrm{eV}}{-15.76868 \mathrm{eV}}=0.68772  \tag{23.86}\\
& c_{2}(\mathrm{NAO} \text { to } \mathrm{V} 3 \mathrm{~d} 4 \mathrm{sHO})=C_{2}(\mathrm{NAO} \text { to } \mathrm{V} 3 \mathrm{~d} 4 \mathrm{sHO})=\frac{E(\mathrm{~V}, 3 d 4 \mathrm{~s})}{E(N A O)}=\frac{-10.83045 \mathrm{eV}}{-14.53414 \mathrm{eV}}=0.74517  \tag{23.87}\\
& c_{2}(\mathrm{O} \text { to } \mathrm{V} 3 \mathrm{~d} 4 \mathrm{sHO})=\frac{E(V, 3 d 4 s)}{E(O)}=\frac{-10.83045 \mathrm{eV}}{-13.61805 \mathrm{eV}}=0.79530 \tag{23.88}
\end{align*}
$$

where Eqs. (15.76), (15.79), and (13.430) were used in Eq. (23.84). Since the energy of the MO is matched to that of the $V 3 d 4 s$ HO of coordinate compounds, $E(A O / H O)$ in Eq. (15.61) is $E(V, 3 d 4 s)$ given by Eq. (23.76) and twice this value for double bonds. For carbonyls and organometallics, the energy of the MO is matched to that of the Coulomb energy of the $V 3 d 4 s \mathrm{HO}$ such that $E(A O / H O)$ in Eq. (15.61) is $E_{\text {Coulomb }}(V, 3 d 4 s)$ given by Eq. (23.73). $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $V-L$-bond MO is determined by considering that the bond involves an electron transfer from the vanadium atom to the ligand atom to form partial ionic character in the bond as in the case of the zwitterions such as $\mathrm{H}_{2} \mathrm{~B}^{+}-\mathrm{F}^{-}$given in the Halido Boranes section. For coordinate compounds, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -2.53109 eV , two times the energy of Eq. (23.81). For carbonyl and organometallic compounds, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -1.65376 eV and -2.26759 eV , respectively. The former is based on the energy match between the $V 3 d 4 s \mathrm{HO}$ and the $C 2 s p^{3} \mathrm{HO}$ of a carbonyl group and is given by the linear combination of -0.72457 eV (Eq. (14.151)) and -0.92918 eV (Eq. (14.513)), respectively. The latter is equivalent to that of ethylene and the aryl group, -2.26759 eV , given by Eq. (14.247). The $C=O$ functional group of carbonyls is equivalent to that of formic acid given in the Carboxylic Acids section except that $\bar{E}_{K v i b}$ corresponds to that of a metal carbonyl and $E_{T}(A O / H O)$ of Eq. (15.47) is:

$$
\begin{equation*}
E_{T}(A O / H O)=-\Delta E_{\mathrm{H}_{2} M O}(A O / H O)=-(-14.63489 \mathrm{eV}-3.58557 \mathrm{eV})=18.22046 \mathrm{eV} \tag{23.89}
\end{equation*}
$$

wherein the additional $E(A O / H O)=-14.63489 \mathrm{eV}$ (Eq. (15.25)) component corresponds to the donation of both unpaired electrons of the $C 2 s p^{3} \mathrm{HO}$ of the carbonyl group to the metal-carbonyl bond. The benzene groups of organometallic, $V\left(C_{6} H_{6}\right)_{2}$ are equivalent to those given in the Aromatic and Heterocyclic Compounds section.

The symbols of the functional groups of vanadium coordinate compounds are given in Table 23.18. The geometrical (Eqs. (15.1-15.5) and (23.41)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of vanadium coordinate compounds are given in Tables 23.19, 23.20, and 23.21, respectively. The total energy of each vanadium coordinate compound given in Table 23.22 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 23.21 corresponding to functional-group composition of the compound. The bond angle parameters of vanadium coordinate compounds determined using Eqs. (15.88-15.117) are given in Table 23.23. The $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ term for $\mathrm{VOCl}_{3}$ was calculated using Eqs. (23.30-23.33) with $s=1$ for the energies of $E(V, 3 d 4 s)$ given by Eqs. (23.78-23.81). The charge-densities of exemplary vanadium carbonyl and organometallic compounds, vanadium hexacarbonyl $\left(V(C O)_{6}\right)$ and dibenzene vanadium $\left(V\left(C_{6} H_{6}\right)_{2}\right)$, respectively, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 23.4A and B.

Figure 23.4. (A) Vanadium Hexacarbonyl. Color scale, translucent view of the charge-density of $V(C O)_{6}$ showing the orbitals of the $V, C$, and $O$ atoms at their radii, the ellipsoidal surface of each $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale). (B) Dibenzene Vanadium. Color scale, translucent view of the charge-density of $V\left(C_{6} H_{6}\right)_{2}$ showing the orbitals of the $V$ and $C$ atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei (red, not to scale).

## CHROMIUM FUNCTIONAL GROUPS AND MOLECULES

The electron configuration of chromium is $[A r] 4 s^{1} 3 d^{5}$ having the corresponding term ${ }^{7} S_{3}$. The total energy of the state is given by the sum over the six electrons. The sum $E_{T}(\mathrm{Cr}, 3 d 4 s)$ of experimental energies [1] of $\mathrm{Cr}, \mathrm{Cr}^{+}, \mathrm{Cr}^{2+}, \mathrm{Cr}^{3+}, \mathrm{Cr}^{4+}$, and $\mathrm{Cr}^{5+}$ is

$$
\begin{equation*}
E_{T}(C r, 3 d 4 s)=-\binom{90.6349 \mathrm{eV}+69.46 \mathrm{eV}+49.16 \mathrm{eV}}{+30.96 \mathrm{eV}+16.4857 \mathrm{eV}+6.76651 \mathrm{eV}}=-263.46711 \mathrm{eV} \tag{23.90}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 d 4 s}$ of the $C r 3 d 4 s$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{3 d 4 s}=\sum_{n=18}^{23} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 263.46711 \mathrm{eV})}=\frac{21 e^{2}}{8 \pi \varepsilon_{0}(e 263.46711 \mathrm{eV})}=1.08447 a_{0} \tag{23.91}
\end{equation*}
$$

where $Z=24$ for chromium. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}(C r, 3 d 4 s)$ of the outer electron of the $\operatorname{Cr} 3 d 4 s$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}(C r, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.08447 a_{0}}=-12.546053 \mathrm{eV} \tag{23.92}
\end{equation*}
$$

Next, consider the formation of the $\mathrm{Cr}-L$-bond MO wherein each chromium atom has a $C r 3 d 4 s$ electron with an energy given by Eq. (23.91). The total energy of the state of each chromium atom is given by the sum over the six electrons. The sum $E_{T}\left(\mathrm{Cr}_{C r-L} 3 d 4 s\right)$ of energies of $\mathrm{Cr} 3 d 4 s$ (Eq. (23.91)), $\mathrm{Cr}^{+}, \mathrm{Cr}^{2+}, \mathrm{Cr}^{3+}, \mathrm{Cr}^{4+}$, and $\mathrm{Cr}^{5+}$ is:

$$
\begin{align*}
E_{T}\left(C r_{C r-L} 3 d 4 s\right) & =-\binom{90.6349 \mathrm{eV}+69.46 \mathrm{eV}+49.16 \mathrm{eV}}{+30.96 \mathrm{eV}+16.4857 \mathrm{eV}+E_{\text {Coulomb }}(\mathrm{Cr}, 3 \mathrm{~d} 4 \mathrm{~s})}  \tag{23.93}\\
& =-\binom{90.6349 \mathrm{eV}+69.46 \mathrm{eV}+49.16 \mathrm{eV}}{+30.96 \mathrm{eV}+16.4857 \mathrm{eV}+12.546053 \mathrm{eV}}=-269.24665 \mathrm{eV}
\end{align*}
$$

where $E(C r, 3 d 4 s)$ is the sum of the energy of $C r,-6.76651 \mathrm{eV}$, and the hybridization energy.
The chromium HO donates an electron to each MO. Using Eq. (23.30), the radius $r_{3 d 4 s}$ of the $C r 3 d 4 s$ shell calculated from the Coulombic energy is:

$$
\begin{equation*}
r_{C r-L 3 d 4 s}=\left(\sum_{n=18}^{23}(Z-n)-1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 269.24665 \mathrm{eV})}=\frac{20 e^{2}}{8 \pi \varepsilon_{0}(e 269.24665 \mathrm{eV})}=1.01066 a_{0} \tag{23.94}
\end{equation*}
$$

Using Eqs. (15.19) and (23.93), the Coulombic energy $E_{C o u l o m b}\left(C r_{C r-L}, 3 d 4 s\right)$ of the outer electron of the $C r 3 d 4 s$ shell is

$$
\begin{equation*}
E_{\text {Coulomb }}\left(C r_{C r-L}, 3 d 4 s\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{C r-L 3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.01066 a_{0}}=-13.46233 \mathrm{eV} \tag{23.95}
\end{equation*}
$$

Thus, $E_{T}(C r-L, 3 d 4 s)$, the energy change of each $C r 3 d 4 s$ shell with the formation of the $C r-L$-bond MO is given by the difference between Eq. (23.94) and Eq. (23.91):

$$
\begin{equation*}
E_{T}(C r-L, 3 d 4 s)=E\left(C r_{C r-L}, 3 d 4 s\right)-E(C r, 3 d 4 s)=-13.46233 \mathrm{eV}-(-12.546053 \mathrm{eV})=-0.91628 \mathrm{eV} \tag{23.96}
\end{equation*}
$$

The semimajor axis $a$ solution given by Eq. (23.41) of the force balance equation, Eq. (23.39), for the $\sigma$-MO of the $C r-L$-bond MO of $C r L_{n}$ is given in Table 23.25 with the force-equation parameters $Z=24, n_{e}$, and $L$ corresponding to the orbital and spin angular momentum terms of the $3 d 4 s \mathrm{HO}$ shell. The semimajor axis $a$ of carbonyl and organometallic compounds are solved using Eq. (15.51).

For the $C r-L$ functional groups, hybridization of the $4 s$ and $3 d$ AOs of $C r$ to form a single $3 d 4 s$ shell forms an energy minimum, and the sharing of electrons between the $\operatorname{Cr} 3 d 4 s \mathrm{HO}$ and $L$ AO to form a MO permits each participating orbital to decrease in radius and energy. The $F \mathrm{AO}$ has an energy of $E(F)=-17.42282 \mathrm{eV}$, the Cl AO has an energy of $E(C l)=-12.96764 \mathrm{eV}$, the $C_{\text {aryl }} 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C_{\text {aryl }}, 2 s p^{3}\right)=-15.76868 \mathrm{eV}$ (Eq. (14.246)), the $C 2 s p^{3}$ HO has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), the $O$ AO has an energy of $E(O)=-13.61805 \mathrm{eV}$, and the Cr 3 d 4 s HO has an energy of $E_{\text {Coulomb }}(C r, 3 d 4 s)=-12.54605 \mathrm{eV}$ (Eq. (23.91)). To meet the equipotential condition of the union of the $\mathrm{Cr}-\mathrm{L}_{2} \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor(s), at least one of $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $\mathrm{Cr}-L$-bond MO given by Eq. (15.77) is:

$$
\begin{align*}
& c_{2}(\text { FAO to Cr } 3 d 4 s \mathrm{HO})=C_{2}(\text { FAO to } \mathrm{Cr} 3 d 4 s H O)=\frac{E_{\text {Coulomb }}(C r, 3 d 4 s)}{E(F A O)}=\frac{-12.54605 \mathrm{eV}}{-17.42282 \mathrm{eV}}=0.72009  \tag{23.97}\\
& c_{2}(\text { ClAO to } \mathrm{Cr} 3 d 4 \mathrm{sHO})=C_{2}(\text { ClAO to } \mathrm{Cr} 3 d 4 \mathrm{sHO})=\frac{E_{\text {Coulomb }}(C r, 3 d 4 \mathrm{~s})}{E(C l A O)}=\frac{-12.54605 \mathrm{eV}}{-12.96764 \mathrm{eV}}=0.96749 \tag{23.98}
\end{align*}
$$

$$
\begin{align*}
& c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to Cr } 3 d 4 s \mathrm{HO}\right)=C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to Cr} 3 d 4 s \mathrm{HO}\right)=\frac{E_{\text {Coulomb }}(C r, 3 d 4 s)}{E\left(C, 2 s p^{3}\right)}=\frac{-12.54605 \mathrm{eV}}{-14.63489 \mathrm{eV}}=0.85727  \tag{23.99}\\
& C_{2}\left(C_{\text {aryl }} 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Cr} 3 d 4 s \mathrm{HO}\right)=\frac{E_{\text {Coulomb }}(C r, 3 d 4 s)}{E\left(C_{\text {aryl }}, 2 s p^{3}\right)}=\frac{-12.54605 \mathrm{eV}}{-15.76868 \mathrm{eV}}=0.79563  \tag{23.100}\\
& c_{2}(\mathrm{O} \text { to } \mathrm{Cr} 3 d 4 \mathrm{sHO})=C_{2}(\mathrm{O} \text { to } \mathrm{Cr} 3 d 4 s H O)=\frac{E_{\text {Coulomb }}(C r, 3 d 4 s)}{E(O)}=\frac{-12.54605 \mathrm{eV}}{-13.61805 \mathrm{eV}}=0.92128 \tag{23.101}
\end{align*}
$$

Since the energy of the MO is matched to that of the $C r_{\text {Coulomb }} 3 d 4 s \mathrm{HO}, E(A O / H O)$ in Eq. (15.61) is $E_{\text {Coulomb }}(C r, 3 d 4 s)$ given by Eq. (23.91) and twice this value for double bonds. $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ of the $C r-L$-bond MO is determined by considering that the bond involves an electron transfer from the chromium atom to the ligand atom to form partial ionic character in the bond as in the case of the zwitterions such as $\mathrm{H}_{2} \mathrm{~B}^{+}-F^{-}$given in the Halido Boranes section. For coordinate compounds, $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ is -1.83256 eV , two times the energy of Eq. (23.95). For carbonyl and organometallic compounds, $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . A O\right)$ is -1.44915 eV (Eq. (14.151)), and the $C=O$ functional group of carbonyls is equivalent to that of vanadium carbonyls. The benzene and substituted benzene groups of organometallics are equivalent to those given in the Aromatic and Heterocyclic Compounds section.

The symbols of the functional groups of chromium coordinate compounds are given in Table 23.24. The corresponding designation of the structure of the $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}_{6} \mathrm{H}_{3}$ group of $\mathrm{Cr}\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}_{6} \mathrm{H}_{3}\right)_{2}$ is equivalent to that of toluene shown in Figure 23.5B. The geometrical (Eqs. (15.1-15.5) and (23.41)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of chromium coordinate compounds are given in Tables 23.25, 23.26, and 23.27, respectively. The total energy of each chromium coordinate compound given in Table 23.28 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 23.27 corresponding to functional-group composition of the compound. The bond angle parameters of chromium coordinate compounds determined using Eqs. (15.88-15.117) are given in Table 23.29. The $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)$ term for $\mathrm{CrOCl}_{3}$ was calculated using Eqs. (23.30-23.33) with $s=1$ for the energies of $E_{\text {Coulomb }}(C r, 3 d 4 s)$ given by Eqs. (23.93-23.95). The charge-densities of exemplary chromium carbonyl and organometallic compounds, chromium hexacarbonyl $\left(\mathrm{Cr}(\mathrm{CO})_{6}\right)$ and di-(1,2,4-trimethylbenzene) chromium $\left(\mathrm{Cr}\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}_{6} \mathrm{H}_{3}\right)_{2}\right)$, respectively, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 23.5A and C.

Figure 23.5. (A) Chromium Hexacarbonyl. Color scale, translucent view of the charge-density of $\mathrm{Cr}(\mathrm{CO})_{6}$ showing the orbitals of the $\mathrm{Cr}, \mathrm{C}$, and O atoms at their radii, the ellipsoidal surface of each $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale). (B) Toluene. (C) Di-(1,2,4trimethylbenzene) Chromium. Color scale, opaque view of the charge-density of $\mathrm{Cr}\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}_{6} \mathrm{H}_{3}\right)_{2}$ showing the orbitals of the Cr and C atoms at their radii and the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond.

## MANGANESE FUNCTIONAL GROUPS AND MOLECULES

The electron configuration of manganese is $[A r] 4 s^{2} 3 d^{5}$ having the corresponding term ${ }^{6} S_{5 / 2}$. The total energy of the state is given by the sum over the seven electrons. The sum $E_{T}(M n, 3 d 4 s)$ of experimental energies [1] of $\mathrm{Mn}, \mathrm{Mn}^{+}, \mathrm{Mn}^{2+}, \mathrm{Mn}^{3+}$, $\mathrm{Mn}^{4+}, \mathrm{Mn}^{5+}$, and $\mathrm{Mn}^{6+}$ is:

$$
\begin{equation*}
E_{T}(M n, 3 d 4 s)=-\binom{119.203 \mathrm{eV}+95.6 \mathrm{eV}+72.4 \mathrm{eV}+51.2 \mathrm{eV}}{+33.668 \mathrm{eV}+15.6400 \mathrm{eV}+14.22133 \mathrm{eV}}=-401.93233 \mathrm{eV} \tag{23.102}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 d 4 s}$ of the $\operatorname{Mn} 3 d 4 s$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{3 d 4 s}=\sum_{n=18}^{24} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 395.14502 \mathrm{eV})}=\frac{28 e^{2}}{8 \pi \varepsilon_{0}(e 395.14502 \mathrm{eV})}=0.96411 a_{0} \tag{23.103}
\end{equation*}
$$

where $Z=25$ for manganese. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}(M n, 3 d 4 s)$ of the outer electron of the $\operatorname{Mn} 3 d 4 s$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}(M n, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.96411 a_{0}}=-14.112322 \mathrm{eV} \tag{23.104}
\end{equation*}
$$

During hybridization, the spin-paired $4 s$ electrons are promoted to the $M n 3 d 4 s$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (15.15) at the initial radius of the $4 s$ electrons. From Eq. (10.102) with $Z=25$ and $n=25$, the radius $r_{25}$ of the $M n 4 s$ shell is:

$$
\begin{equation*}
r_{25}=1.83021 a_{0} \tag{23.105}
\end{equation*}
$$

Using Eqs. (15.15) and (23.104), the unpairing energy is:

$$
\begin{equation*}
E_{4 s}(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{25}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(1.83021 a_{0}\right)^{3}}=0.01866 \mathrm{eV} \tag{23.106}
\end{equation*}
$$

The electrons from the $4 s$ and $3 d$ shells successively fill unoccupied HOs until the HO shell is filled with unpaired electrons, then the electrons pair per HO. In the case of the $\operatorname{Mn} 3 d 4 s$ shell having seven electrons and six orbitals, one set of electrons is paired. Using Eqs. (15.15) and (23.102), the pairing energy is given by:

$$
\begin{equation*}
E_{3 d 4 s}(\text { magnetic })=-\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3 d 4 s}\right)^{3}}=-\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.96411 a_{0}\right)^{3}}=-0.12767 \mathrm{eV} \tag{23.107}
\end{equation*}
$$

Thus, after Eq. (23.28), the energy $E(M n, 3 d 4 s)$ of the outer electron of the $M n 3 d 4 s$ shell is given by adding the magnetic energy of unpairing the $4 s$ electrons (Eq. (23.105)) and pairing of one set of $M n 3 d 4 s$ electrons (Eq. (23.106)) to $E_{\text {Coulomb }}(M n, 3 d 4 s)$ (Eq. (23.103)).

$$
\begin{align*}
E(M n, 3 d 4 s) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{4 s}^{3}}+\sum_{3 d \text { pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d}^{3}}-\sum_{H O \text { pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d 4 s}^{3}}  \tag{23.108}\\
& =-14.112322 \mathrm{eV}+0.01866 \mathrm{eV}-0.12767 \mathrm{eV}=-14.22133 \mathrm{eV}
\end{align*}
$$

Next, consider the formation of the $M n-L$-bond MO wherein each manganese atom has a $M n 3 d 4 s$ electron with an energy given by Eq. (23.107). The total energy of the state of each manganese atom is given by the sum over the seven electrons. The sum $E_{T}\left(M n_{M n-L} 3 d 4 s\right)$ of energies of $M n 3 d 4 s$ (Eq. (23.107)), $\mathrm{Mn}^{+}, \mathrm{Mn}^{2+}, \mathrm{Mn}^{3+}, \mathrm{Mn}^{4+}, \mathrm{Mn}^{5+}$, and $\mathrm{Mn}^{6+}$ is:

$$
\begin{align*}
E_{T}\left(M n_{M n-L} 3 d 4 s\right) & =-\binom{119.203 \mathrm{eV}+95.6 \mathrm{eV}+72.4 \mathrm{eV}+51.2 \mathrm{eV}}{+33.668 \mathrm{eV}+15.6400 \mathrm{eV}+E(M n, 3 \mathrm{~d} 4 \mathrm{~s})} \\
& =-\binom{119.203 \mathrm{eV}+95.6 \mathrm{eV}+72.4 \mathrm{eV}+51.2 \mathrm{eV}}{+33.668 \mathrm{eV}+15.6400 \mathrm{eV}+14.22133 \mathrm{eV}}  \tag{23.109}\\
& =-401.93233 \mathrm{eV}
\end{align*}
$$

where $E(M n, 3 d 4 s)$ is the sum of the energy of $M n,-7.43402 \mathrm{eV}$, and the hybridization energy.
The manganese HO donates an electron to each MO. Using Eq. (23.30), the radius $r_{3 d 4 s}$ of the Mn3d4s shell calculated from the Coulombic energy is:

$$
\begin{equation*}
r_{M n-L 3 d 4 s}=\left(\sum_{n=18}^{24}(Z-n)-1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 401.93233 \mathrm{eV})}=\frac{27 e^{2}}{8 \pi \varepsilon_{0}(e 401.93233 \mathrm{eV})}=0.91398 a_{0} \tag{23.110}
\end{equation*}
$$

Using Eqs. (15.19) and (23.109), the Coulombic energy $E_{\text {Coulomb }}\left(M n_{M n-L}, 3 d 4 s\right)$ of the outer electron of the $M n 3 d 4 s$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(M n_{M n-L}, 3 d 4 s\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{M n-L 3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.91398 a_{0}}=-14.88638 \mathrm{eV} \tag{23.111}
\end{equation*}
$$

The magnetic energy terms are those for the unpairing of the $4 s$ electrons (Eq. (23.105)) and pairing one set of $M n 3 d 4 s$ electrons (Eq. (23.106)). Using Eqs. (23.32), (23.105), (23.106), and (23.110), the energy $E\left(M n_{M n-L}, 3 d 4 s\right)$ of the outer electron of the $M n 3 d 4 s$ shell is:

$$
\begin{align*}
E\left(M n_{M n-L}, 3 d 4 s\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{M n-L 3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{25}\right)^{3}}-\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3 d 4 s}\right)^{3}}  \tag{23.112}\\
& =-14.88638 \mathrm{eV}+0.01866 \mathrm{eV}-0.12767 \mathrm{eV}=-14.99539 \mathrm{eV}
\end{align*}
$$

Thus, $E_{T}(M n-L, 3 d 4 s)$, the energy change of each $\operatorname{Mn} 3 d 4 s$ shell with the formation of the $M n-L$-bond MO is given by the difference between Eq. (23.111) and Eq. (23.107):

$$
\begin{align*}
E_{T}(M n-L, 3 d 4 s) & =E\left(M n_{M n-L}, 3 d 4 s\right)-E(M n, 3 d 4 s)  \tag{23.113}\\
& =-14.99539 \mathrm{eV}-(-14.22133 \mathrm{eV})=-0.77406 \mathrm{eV}
\end{align*}
$$

The semimajor axis $a$ solution given by Eq. (23.41) of the force balance equation, Eq. (23.39), for the $\sigma$-MO of the $M n-L$-bond MO of $M n L_{n}$ is given in Table 23.31 with the force-equation parameters $Z=25, n_{e}$, and $L$ corresponding to the orbital and spin angular momentum terms of the $3 d 4 s$ HO shell. The semimajor axis $a$ of carbonyl and organometallic compounds are solved using Eq. (15.51).

For the $M n-L$ functional groups, hybridization of the $4 s$ and $3 d$ AOs of $M n$ to form a single $3 d 4 s$ shell forms an energy minimum, and the sharing of electrons between the $M n 3 d 4 s$ HO and $L$ AO to form a MO permits each participating orbital to decrease in radius and energy. The $F$ AO has an energy of $E(F)=-17.42282 \mathrm{eV}$, the Cl AO has an energy of $E(C l)=-12.96764 \mathrm{eV}$, the $C 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), the Coulomb energy of $\operatorname{Mn} 3 d 4 s \quad \mathrm{HO}$ is $E_{\text {Coulomb }}(M n, 3 d 4 s)=-14.11232 \mathrm{eV} \quad$ (Eq. (23.103)), the $M n 3 d 4 s \quad \mathrm{HO}$ has an energy of $E(M n, 3 d 4 s)=-14.22133 \mathrm{eV}$ (Eq. (23.107)), and 13.605804 eV is the magnitude of the Coulombic energy between the electron and proton of $H$ (Eq. (1.264)). To meet the equipotential condition of the union of the $M n-L H_{2}$-type-ellipsoidalMO with these orbitals, the hybridization factor(s), at least one of $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $M n-L$-bond MO given by Eq. (15.77) is:

$$
\begin{align*}
& C_{2}(F A O \text { to Mn3d } 4 s H O)=\frac{E(M n, 3 d 4 s)}{E(F A O)}=\frac{-14.22133 \mathrm{eV}}{-17.42282 \mathrm{eV}}=0.81625  \tag{23.114}\\
& C_{2}(\mathrm{ClAO} \text { to Mn } 3 d 4 s H O)=\frac{E(C l A O)}{E(M n, 3 d 4 s)}=\frac{-12.96764 \mathrm{eV}}{-14.22133 \mathrm{eV}}=0.91184  \tag{23.115}\\
& c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Mn} 3 d 4 s H O\right)=\frac{E_{\text {Coulomb }}(M n, 3 d 4 s)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(\mathrm{C} 2 s p^{3} \mathrm{HO}\right)=\frac{-14.11232 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.88495  \tag{23.116}\\
& C_{2}(\mathrm{Mn} 3 d 4 \mathrm{sHO} \text { to } \mathrm{Mn} 3 d 4 s \mathrm{HO})=\frac{E(H)}{E_{\text {Coulomb }}(M n, 3 d 4 s)}=\frac{-13.605804 \mathrm{eV}}{-14.11232 \mathrm{eV}}=0.96411 \tag{23.117}
\end{align*}
$$

where Eqs. (15.76), (15.79), and (13.430) were used in Eq. (23.115) and Eq. (15.71) was used in Eq. (23.116). Since the energy of the MO is matched to that of the $\mathrm{Mn} 3 d 4 s \mathrm{HO}$ in coordinate compounds, $E(A O / H O)$ in Eq. (15.61) is $E(M n, 3 d 4 s)$ given by Eq. (23.107) and $E(A O / H O)$ in Eq. (15.61) of carbonyl compounds is $E_{\text {Coulomb }}(M n, 3 d 4 s)$ given by Eq. (23.103). $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $M n-L$-bond MO is determined by considering that the bond involves an electron transfer from the manganese atom to the ligand atom to form partial ionic character in the bond as in the case of the zwitterions such as $H_{2} B^{+}-F^{-}$given in the Halido Boranes section. For the coordinate compounds, $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)$ is -1.54812 eV , two times the energy of Eq. (23.112). For the $M n-C O$ bonds of carbonyl compounds, $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ is -1.44915 eV (Eq. (14.151)), and the $C=O$ functional group of carbonyls is equivalent to that of vanadium carbonyls.

The symbols of the functional groups of manganese coordinate compounds are given in Table 23.30. The geometrical (Eqs. (15.1-15.5) and (23.41)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of manganese coordinate compounds are given in Tables 23.31, 23.32, and 23.33, respectively. The total energy of each manganese coordinate compound given in Table 23.34 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 23.33 corresponding to functional-group composition of the compound. The charge-densities of exemplary manganese carbonyl compound, dimanganese decacarbonyl ( $\mathrm{Mn}_{2}(\mathrm{CO})_{10}$ ) comprising the concentric shells of atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 23.6.

Figure 23.6. Diamanganese decacarbonyl. Color scale, opaque view of the charge-density of $M n_{2}(\mathrm{CO})_{10}$ showing the orbitals of the $\mathrm{Mn}, \mathrm{C}$, and O atoms at their radii and the ellipsoidal surface of each $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond.

## IRON FUNCTIONAL GROUPS AND MOLECULES

The electron configuration of iron is $[A r] 4 s^{2} 3 d^{6}$ having the corresponding term ${ }^{5} D_{4}$. The total energy of the state is given by the sum over the eight electrons. The sum $E_{T}(\mathrm{Fe}, 3 \mathrm{~d} 4 \mathrm{~s})$ of experimental energies [1] of $\mathrm{Fe}, \mathrm{Fe}^{+}, \mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Fe}^{4+}, \mathrm{Fe}^{5+}$, $F e^{6+}$, and $F e^{7+}$ is:

$$
\begin{equation*}
E_{T}(F e, 3 d 4 s)=-\binom{151.06 \mathrm{eV}+124.98 \mathrm{eV}+99.1 \mathrm{eV}+75.0 \mathrm{eV}}{+54.8 \mathrm{eV}+30.652 \mathrm{eV}+16.1877 \mathrm{eV}+7.9024 \mathrm{eV}}=-559.68210 \mathrm{eV} \tag{23.118}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 d 4 s}$ of the $F e 3 d 4 s$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{3 d 4 s}=\sum_{n=18}^{25} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 559.68210 \mathrm{eV})}=\frac{36 e^{2}}{8 \pi \varepsilon_{0}(e 559.68210 \mathrm{eV})}=0.87516 a_{0} \tag{23.119}
\end{equation*}
$$

where $Z=26$ for iron. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}(F e, 3 d 4 s)$ of the outer electron of the $F e 3 d 4 s$ shell is

$$
\begin{equation*}
E_{\text {Coulomb }}(F e, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.87516 a_{0}}=-15.546725 \mathrm{eV} \tag{23.120}
\end{equation*}
$$

During hybridization, the spin-paired $4 s$ electrons and the one set of paired $3 d$ electrons are promoted to the $F e 3 d 4 s$ shell as initially unpaired electrons. The energies for the promotions are given by Eq. (15.15) at the initial radii of the $4 s$ and $3 d$ electrons. From Eq. (10.102) with $Z=26$ and $n=26$, the radius $r_{26}$ of the Fe4s shell is

$$
\begin{equation*}
r_{26}=1.72173 a_{0} \tag{23.121}
\end{equation*}
$$

and with $Z=26$ and $n=24$, the radius $r_{24}$ of the $F e 3 d$ shell is:

$$
\begin{equation*}
r_{24}=1.33164 a_{0} \tag{23.122}
\end{equation*}
$$

Using Eqs. (15.15), (23.120), and (23.121), the unpairing energies are:

$$
\begin{align*}
& E_{4 s}(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{26}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(1.72173 a_{0}\right)^{3}}=0.02242 \mathrm{eV}  \tag{23.123}\\
& E_{3 d}(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{24}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(1.33164 a_{0}\right)^{3}}=0.04845 \mathrm{eV} \tag{23.124}
\end{align*}
$$

The electrons from the $4 s$ and $3 d$ shells successively fill unoccupied HOs until the HO shell is filled with unpaired electrons, then the electrons pair per HO. In the case of the $F e 3 d 4 s$ shell having eight electrons and six orbitals, two sets of electrons are paired. Using Eqs. (15.15) and (23.118), the pairing energy is given by:

$$
\begin{equation*}
E_{3 d 4 s}(\text { magnetic })=-\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3 d 4 s}\right)^{3}}=-\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.87516 a_{0}\right)^{3}}=-0.17069 \mathrm{eV} \tag{23.125}
\end{equation*}
$$

Thus, after Eq. (23.28), the energy $E(F e, 3 d 4 s)$ of the outer electron of the $F e 3 d 4 s$ shell is given by adding the magnetic energies of unpairing the $4 s$ (Eq. (23.122)) and $3 d$ electrons (Eq. (23.123)) and pairing of two sets of Fe3d4s electrons (Eq. (23.124)) to $E_{\text {Coulomb }}(F e, 3 d 4 s)$ (Eq. (23.119)).

$$
\begin{align*}
E(F e, 3 d 4 s) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{4 s}^{3}}+\sum_{3 d \text { pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d}^{3}}-\sum_{H O \text { pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d 4 s}^{3}}  \tag{23.126}\\
& =-15.546725 \mathrm{eV}+0.02242 \mathrm{eV}+0.04845 \mathrm{eV}-2(0.17069 \mathrm{eV})=-15.81724 \mathrm{eV}
\end{align*}
$$

Next, consider the formation of the $F e-L$-bond MO wherein each iron atom has an $F e 3 d 4 s$ electron with an energy given by Eq. (23.125). The total energy of the state of each iron atom is given by the sum over the eight electrons. The sum $E_{T}\left(F e_{F e-L} 3 d 4 s\right)$ of energies of $F e 3 d 4 s$ (Eq. (23.125)), $F e^{+}, F e^{2+}, F e^{3+}, F e^{4+}, F e^{5+}, F e^{6+}$, and $F e^{7+}$ is:

$$
\begin{align*}
E_{T}\left(F e_{F e-L} 3 d 4 s\right) & =-\binom{151.06 \mathrm{eV}+124.98 \mathrm{eV}+99.1 \mathrm{eV}+75.0 \mathrm{eV}}{+54.8 \mathrm{eV}+30.652 \mathrm{eV}+16.1877 \mathrm{eV}+E(F e, 3 \mathrm{~d} 4 \mathrm{~s})} \\
& =-\binom{151.06 \mathrm{eV}+124.98 \mathrm{eV}+99.1 \mathrm{eV}+75.0 \mathrm{eV}}{+54.8 \mathrm{eV}+30.652 \mathrm{eV}+16.1877 \mathrm{eV}+15.81724 \mathrm{eV}}=-567.59694 \mathrm{eV} \tag{23.127}
\end{align*}
$$

where $E(F e, 3 d 4 s)$ is the sum of the energy of $F e,-7.9024 \mathrm{eV}$, and the hybridization energy.
The iron HO donates an electron to each MO. Using Eq. (23.30), the radius $r_{3 d 4 s}$ of the $F e 3 d 4 s$ shell calculated from the Coulombic energy is:

$$
\begin{equation*}
r_{F e-L 3 d 4 s}=\left(\sum_{n=18}^{25}(Z-n)-1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 567.59694 \mathrm{eV})}=\frac{35 e^{2}}{8 \pi \varepsilon_{0}(e 567.59694 \mathrm{eV})}=0.83898 a_{0} \tag{23.128}
\end{equation*}
$$

Using Eqs. (15.19) and (23.127), the Coulombic energy $E_{\text {Coulomb }}\left(F e_{F e-L}, 3 d 4 s\right)$ of the outer electron of the $F e 3 d 4 s$ shell is

$$
\begin{equation*}
E_{\text {Coulomb }}\left(F e_{F e-L}, 3 d 4 s\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{F e-L 3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.83898 a_{0}}=-16.21706 \mathrm{eV} \tag{23.129}
\end{equation*}
$$

The magnetic energy terms are those for the unpairing of the $4 s$ and $3 d$ electrons (Eqs. (23.122) and (23.123), respectively) and paring two sets of $F e 3 d 4 s$ electrons (Eq. (23.124)). Using Eqs. (23.32), (23.128) and (23.122-23.124), the energy $E\left(F e_{F e-L}, 3 d 4 s\right)$ of the outer electron of the $F e 3 d 4 s$ shell is:

$$
\begin{align*}
E\left(F e_{F e-L}, 3 d 4 s\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{F e-L 3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{26}\right)^{3}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{24}\right)^{3}}-2 \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3 d 4 s}\right)^{3}}  \tag{23.130}\\
& =-16.21706 \mathrm{eV}+0.02242 \mathrm{eV}+0.04845 \mathrm{eV}-2(0.17069 \mathrm{eV})=-16.48757 \mathrm{eV}
\end{align*}
$$

Thus, $E_{T}(F e-L, 3 d 4 s)$, the energy change of each $F e 3 d 4 s$ shell with the formation of the $F e-L$-bond MO is given by the difference between Eq. (23.129) and Eq. (23.125):

$$
\begin{equation*}
E_{T}(F e-L, 3 d 4 s)=E\left(F e_{F e-L}, 3 d 4 s\right)-E(F e, 3 d 4 s)=-16.48757 \mathrm{eV}-(-15.81724 \mathrm{eV})=-0.67033 \mathrm{eV} \tag{23.131}
\end{equation*}
$$

The semimajor axis $a$ solution given by Eq. (23.41) of the force balance equation, Eq. (23.39), for the $\sigma$-MO of the $F e-L$-bond MO of $F e L_{n}$ is given in Table 23.36 with the force-equation parameters $Z=26, n_{e}$, and $L$ corresponding to the orbital and spin angular momentum terms of the $3 d 4 s \mathrm{HO}$ shell. The semimajor axis $a$ of carbonyl and organometallic compounds are solved using Eq. (15.51).

For the $F e-L$ functional groups, hybridization of the $4 s$ and $3 d$ AOs of $F e$ to form a single $3 d 4 s$ shell forms an energy minimum, and the sharing of electrons between the $F e 3 d 4 s \mathrm{HO}$ and $L \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. The $F \mathrm{AO}$ has an energy of $E(F)=-17.42282 \mathrm{eV}$, the Cl AO has an energy of $E(C l)=-12.96764 \mathrm{eV}$, the $C_{\text {aryl }} 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C_{\text {aryl }}, 2 s p^{3}\right)=-15.76868 \mathrm{eV}$ (Eq. (14.246)), the $C 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), the $O$ AO has an energy of $E(O)=-13.61805 \mathrm{eV}$, the Coulomb energy of $\mathrm{Fe} 3 d 4 \mathrm{~s} \mathrm{HO}$ is $E_{\text {Coulomb }}(F e, 3 d 4 s)=-15.546725 \mathrm{eV}$ (Eq. (23.119)), and the Fe3d4s HO has an energy of $E(F e, 3 d 4 s)=-15.81724 \mathrm{eV}$ (Eq. (23.125)). To meet the equipotential condition of the union of the $\mathrm{Fe}-L \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor(s), at least one of $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $F e-L$-bond MO given by Eq. (15.77) is:

$$
\begin{align*}
& c_{2}(F A O \text { to } \mathrm{Fe} 3 d 4 \mathrm{sHO})=C_{2}(F A O \text { to } \mathrm{Fe} 3 d 4 \mathrm{sHO})=\frac{E(F e, 3 d 4 s)}{E(F A O)}=\frac{-15.81724 \mathrm{eV}}{-17.42282 \mathrm{eV}}=0.90785  \tag{23.132}\\
& c_{2}(\mathrm{ClAO} \text { to } \mathrm{Fe} 3 \mathrm{~d} 4 \mathrm{sHO})=\mathrm{C}_{2}(\mathrm{ClAO} \text { to } \mathrm{Fe} 3 \mathrm{~d} 4 \mathrm{sHO})=\frac{E(\mathrm{ClAO})}{E(\mathrm{Fe}, 3 d 4 \mathrm{~s})}=\frac{-12.96764 \mathrm{eV}}{-15.81724 \mathrm{eV}}=0.81984  \tag{23.133}\\
& c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Fe} 3 d 4 s \mathrm{HO}\right)=\frac{E\left(C, 2 s p^{3}\right)}{E_{\text {Coulomb }}(F e, 3 d 4 s)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-14.63489 \mathrm{eV}}{-15.54673 \mathrm{eV}}(0.91771)=0.86389  \tag{23.134}\\
& c_{2}\left(C_{\text {aryl }} 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Fe} 3 \mathrm{~d} 4 \mathrm{sHO}\right)=\mathrm{C}_{2}\left(C_{\text {aryl }} 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Fe} 3 d 4 s \mathrm{HO}\right) \\
& =\frac{E\left(C, 2 s p^{3}\right)}{E_{\text {Coulomb }}(F e, 3 d 4 s)} c_{2}\left(C_{\text {aryl }} 2 s p^{3} \mathrm{HO}\right)=\frac{-14.63489 \mathrm{eV}}{-15.54673 \mathrm{eV}}(0.85252)=0.80252  \tag{23.135}\\
& c_{2}(O \text { to Fe3d } 4 \mathrm{sHO})=C_{2}(O \text { to } \mathrm{Fe} 3 d 4 \mathrm{sHO})=\frac{E(O)}{E(F e, 3 d 4 \mathrm{~s})}=\frac{-13.61805 \mathrm{eV}}{-15.81724 \mathrm{eV}}=0.86096 \tag{23.136}
\end{align*}
$$

where Eqs. (15.76), (15.79), and (13.430) were used in Eq. (23.133) and Eqs. (15.76), (15.79), and (14.417) were used in Eq. (23.134). Since the energy of the MO is matched to that of the Fe 3 d 4 s HO in coordinate compounds, $E(A O / H O)$ in Eq. (15.61) is $E(F e, 3 d 4 s)$ given by Eq. (23.125) and $E(A O / H O)$ in Eq. (15.61) of carbonyl and organometallic compounds is $E_{\text {Coulomb }}(F e, 3 d 4 s)$ given by Eq. (23.119). $\quad E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $F e-L$-bond MO is determined by considering that the bond involves an electron transfer from the iron atom to the ligand atom to form partial ionic character in the bond as in the case of the zwitterions such as $H_{2} B^{+}-F^{-}$given in the Halido Boranes section. For the coordinate compounds, $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)$ is -1.34066 eV , two times the energy of Eq. (23.130). For the $\mathrm{Fe}-\mathrm{C}$ bonds of carbonyl and organometallic compounds, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -1.44915 eV (Eq. (14.151)), and the $C=O$ functional group of carbonyls is equivalent to that of vanadium carbonyls. The aromatic cyclopentadienyl moieties of organometallic $\mathrm{Fe}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2}$ comprise $C \stackrel{3 e}{=} C$ and $C H$ functional groups that are equivalent to those given in the Aromatic and Heterocyclic Compounds section.

The symbols of the functional groups of iron coordinate compounds are given in Table 23.35. The geometrical (Eqs. (15.1-15.5) and (23.41)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of iron coordinate compounds are given in Tables 23.36, 23.37, and 23.38, respectively. The total energy of each iron coordinate compound given in Table 23.39 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 23.38 corresponding to functional-group composition of the compound. The charge-densities of exemplary iron carbonyl and organometallic compounds, iron pentacarbonyl $\left(\mathrm{Fe}(\mathrm{CO})_{5}\right)$ and bis-cylopentadienyl iron or ferrocene ( $\mathrm{Fe}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2}$ ) comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 23.7 and 23.8, respectively.

Figure 23.7. Iron Pentacarbonyl. Color scale, translucent view of the charge-density of $\mathrm{Fe}(\mathrm{CO})_{5}$ showing the orbitals of the $F e, C$, and $O$ atoms at their radii, the ellipsoidal surface of each $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale).

Figure 23.8. Bis-cylopentadienyl Iron. Color scale, opaque view of the charge-density of $\mathrm{Fe}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2}$ showing the orbitals of the Fe and C atoms at their radii and the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond.

Table 23.35. The symbols of the functional groups of iron coordinate compounds.

| Functional Group | Group Symbol |
| :---: | :---: |
| FeF group of FeF | $F e-F$ (a) |
| $\mathrm{FeF}_{2}$ group of $\mathrm{FeF}_{2}$ | $F e-F(b)$ |
| $\mathrm{FeF}_{3}$ group of $\mathrm{FeF}_{3}$ | $F e-F$ (c) |
| FeCl group of FeCl | $\mathrm{Fe}-\mathrm{Cl}$ (a) |
| $\mathrm{FeCl}_{2}$ group of $\mathrm{FeCl}_{2}$ | $\mathrm{Fe}-\mathrm{Cl}$ (b) |
| $\mathrm{FeCl}_{3}$ group of $\mathrm{FeCl}_{3}$ | $\mathrm{Fe}-\mathrm{Cl}$ (c) |
| FeO group of FeO | $\mathrm{Fe}-\mathrm{O}$ |
| FeCO group of $\mathrm{Fe}(\mathrm{CO})_{5}$ | $\mathrm{Fe}-\mathrm{CO}$ |
| $C=O$ | $C=O$ |
|  | $\mathrm{Fe}-\mathrm{C}_{5} \mathrm{H}_{5}$ |
| $C C$ (aromatic bond) | $C \stackrel{3 e}{=} C$ |
| CH (aromatic) | CH |

## COBALT FUNCTIONAL GROUPS AND MOLECULES

The electron configuration of cobalt is $[A r] 4 s^{2} 3 d^{7}$ having the corresponding term ${ }^{4} F_{9 / 2}$. The total energy of the state is given by the sum over the nine electrons. The sum $E_{T}(\mathrm{Co}, 3 \mathrm{~d} 4 \mathrm{~s})$ of experimental energies $[1]$ of $\mathrm{Co}, \mathrm{Co}^{+}, \mathrm{Co}^{2+}, \mathrm{Co}^{3+}, \mathrm{Co}^{4+}, \mathrm{Co}^{5+}$, $\mathrm{Co}^{6+}, \mathrm{Co}^{7+}$, and $\mathrm{Co}^{8+}$ is:

$$
\begin{equation*}
E_{T}(C o, 3 d 4 s)=-\binom{186.13 \mathrm{eV}+157.8 \mathrm{eV}+128.9 \mathrm{eV}+102.0 \mathrm{eV}+79.5 \mathrm{eV}}{+51.3 \mathrm{eV}+33.50 \mathrm{eV}+17.084 \mathrm{eV}+7.88101 \mathrm{eV}}=-764.09501 \mathrm{eV} \tag{23.137}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 d 4 s}$ of the $\operatorname{Co3d} 4 s$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{3 d 4 s}=\sum_{n=18}^{26} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 764.09501 \mathrm{eV})}=\frac{45 e^{2}}{8 \pi \varepsilon_{0}(e 764.09501 \mathrm{eV})}=0.80129 a_{0} \tag{23.138}
\end{equation*}
$$

where $Z=27$ for cobalt. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}(\operatorname{Co}, 3 d 4 s)$ of the outer electron of the Co3d $4 s$ shell is

$$
\begin{equation*}
E_{\text {Coulomb }}(\operatorname{Co}, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.80129 a_{0}}=-16.979889 \mathrm{eV} \tag{23.139}
\end{equation*}
$$

During hybridization, the spin-paired $4 s$ electrons and the two sets of paired $3 d$ electrons are promoted to the $C o 3 d 4 s$ shell as initially unpaired electrons. The energies for the promotions are given by Eq. (15.15) at the initial radii of the $4 s$ and $3 d$ electrons. From Eq. (10.102) with $Z=27$ and $n=27$, the radius $r_{27}$ of the Co4s shell is:

$$
\begin{equation*}
r_{27}=1.72640 a_{0} \tag{23.140}
\end{equation*}
$$

and with $Z=27$ and $n=25$, the radius $r_{25}$ of the Co3d shell is:

$$
\begin{equation*}
r_{25}=1.21843 a_{0} \tag{23.141}
\end{equation*}
$$

Using Eqs. (15.15), (23.139), and (23.140), the unpairing energies are:

$$
\begin{align*}
& E_{4 s}(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{27}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(1.72640 a_{0}\right)^{3}}=0.02224 \mathrm{eV}  \tag{23.142}\\
& E_{3 d}(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{25}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(1.21843 a_{0}\right)^{3}}=0.06325 \mathrm{eV} \tag{23.143}
\end{align*}
$$

The electrons from the $4 s$ and $3 d$ shells successively fill unoccupied HOs until the HO shell is filled with unpaired electrons, then the electrons pair per HO. In the case of the $\operatorname{Co} 3 d 4 s$ shell having nine electrons and six orbitals, three sets of electrons are paired. Using Eqs. (15.15) and (23.137), the pairing energy is given by:

$$
\begin{equation*}
E_{3 d 4 s}(\text { magnetic })=-\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3 d 4 s}\right)^{3}}=-\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.80129 a_{0}\right)^{3}}=-0.22238 \mathrm{eV} \tag{23.144}
\end{equation*}
$$

Thus, after Eq. (23.28), the energy $E(\operatorname{Co}, 3 d 4 s)$ of the outer electron of the $\operatorname{Co} 3 d 4 s$ shell is given by adding the magnetic energies of unpairing the $4 s$ (Eq. (23.141)) and 3d electrons (Eq. (23.142)) and pairing of three sets of Co3d4s electrons (Eq. (23.143)) to $E_{\text {Coulomb }}(C o, 3 d 4 s)$ (Eq. (23.138)).

$$
\begin{align*}
E(C o, 3 d 4 s) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{4 s}^{3}}+\sum_{3 d \text { pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d}^{3}}-\sum_{\text {HO pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d 4 s}^{3}}  \tag{23.145}\\
& =-16.979889 \mathrm{eV}+0.02224 \mathrm{eV}+2(0.06325 \mathrm{eV})-3(0.22238 \mathrm{eV})=-17.49830 \mathrm{eV}
\end{align*}
$$

Next, consider the formation of the $C o-L$-bond MO wherein each cobalt atom has an Co3d $4 s$ electron with an energy given by Eq. (23.144). The total energy of the state of each cobalt atom is given by the sum over the nine electrons. The sum $E_{T}\left(\mathrm{Co}_{\mathrm{Co-L}} 3 \mathrm{~d} 4 \mathrm{~s}\right)$ of energies of $\mathrm{Co3d} 4 \mathrm{~s}$ (Eq. (23.144)), $\mathrm{Co}^{+}, \mathrm{Co}^{2+}, \mathrm{Co}^{3+}, \mathrm{Co}^{4+}, \mathrm{Co}^{5+}, \mathrm{Co}^{6+}, \mathrm{Co}^{7+}$, and $\mathrm{Co}^{8+}$ is:

$$
\begin{align*}
E_{T}\left(C o_{C o-L} 3 d 4 s\right) & =-\binom{186.13 \mathrm{eV}+157.8 \mathrm{eV}+128.9 \mathrm{eV}+102.0 \mathrm{eV}+79.5 \mathrm{eV}}{+51.3 \mathrm{eV}+33.50 \mathrm{eV}+17.084 \mathrm{eV}+E(C o, 3 d 4 s)}  \tag{23.146}\\
& =-\binom{186.13 \mathrm{eV}+157.8 \mathrm{eV}+128.9 \mathrm{eV}+102.0 \mathrm{eV}+79.5 \mathrm{eV}}{+51.3 \mathrm{eV}+33.50 \mathrm{eV}+17.084 \mathrm{eV}+17.49830 \mathrm{eV}}=-773.71230 \mathrm{eV}
\end{align*}
$$

where $E(C o, 3 d 4 s)$ is the sum of the energy of $C o,-7.88101 \mathrm{eV}$, and the hybridization energy.
The cobalt HO donates an electron to each MO. Using Eq. (23.30), the radius $r_{3 d 4 s}$ of the $\operatorname{Co3d} 4 s$ shell calculated from the Coulombic energy is:

$$
\begin{equation*}
r_{C o-L 3 d 4 s}=\left(\sum_{n=18}^{26}(Z-n)-1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 773.71230 \mathrm{eV})}=\frac{44 e^{2}}{8 \pi \varepsilon_{0}(e 773.71230 \mathrm{eV})}=0.77374 a_{0} \tag{23.147}
\end{equation*}
$$

Using Eqs. (15.19) and (23.146), the Coulombic energy $E_{\text {Coulomb }}\left(\operatorname{Co}_{C o-L}, 3 d 4 s\right)$ of the outer electron of the $C o 3 d 4 s$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(C o_{C o-L}, 3 d 4 s\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{C o-L 3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.77374 a_{0}}=-17.58437 \mathrm{eV} \tag{23.148}
\end{equation*}
$$

The magnetic energy terms are those for the unpairing of the $4 s$ and $3 d$ electrons (Eqs. (23.141) and (23.142), respectively) and paring three sets of Co3d4s electrons (Eq. (23.143)). Using Eqs. (23.32), (23.148) and (23.141-23.143), the energy $E\left(C o_{C o-L}, 3 d 4 s\right)$ of the outer electron of the $\operatorname{Co} 3 d 4 s$ shell is:

$$
\begin{align*}
E\left(C o_{C o-L}, 3 d 4 s\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{F e-L 3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{27}\right)^{3}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{25}\right)^{3}}-3 \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3 d 4 s}\right)^{3}}  \tag{23.149}\\
& =-17.58437 \mathrm{eV}+0.02224 \mathrm{eV}+2(0.06325 \mathrm{eV})-3(0.22238 \mathrm{eV})=-18.10278 \mathrm{eV}
\end{align*}
$$

Thus, $E_{T}(C o-L, 3 d 4 s)$, the energy change of each $\operatorname{Co} 3 d 4 s$ shell with the formation of the $C o-L$-bond MO is given by the difference between Eq. (23.148) and Eq. (23.144):

$$
\begin{equation*}
E_{T}(C o-L, 3 d 4 s)=E\left(C o_{C o-L}, 3 d 4 s\right)-E(C o, 3 d 4 s)=-18.10278 \mathrm{eV}-(-17.49830 \mathrm{eV})=-0.60448 \mathrm{eV} \tag{23.150}
\end{equation*}
$$

The semimajor axis $a$ solution given by Eq. (23.41) of the force balance equation, Eq. (23.39), for the $\sigma$-MO of the $C o-L$-bond MO of $C o L_{n}$ is given in Table 23.41 with the force-equation parameters $Z=27, n_{e}$, and $L$ corresponding to the orbital and spin angular momentum terms of the $3 d 4 s \mathrm{HO}$ shell. The semimajor axis $a$ of carbonyl and organometallic compounds are solved using Eq. (15.51).

For the Co-L functional groups, hybridization of the $4 s$ and $3 d$ AOs of Co to form a single $3 d 4 s$ shell forms an energy minimum, and the sharing of electrons between the $\operatorname{Co} 3 d 4 s \mathrm{HO}$ and $L \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. The $F \mathrm{AO}$ has an energy of $E(F)=-17.42282 \mathrm{eV}$, the Cl AO has an energy of $E(C l)=-12.96764 \mathrm{eV}$, the $C 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), the Coulomb energy of $\operatorname{Co3d} 4 s \mathrm{HO}$ is $E_{\text {Coulomb }}(\operatorname{Co}, 3 d 4 s)=-16.979889 \mathrm{eV}$ (Eq. (23.138)), 13.605804 eV is the magnitude of the Coulombic energy between the electron and proton of $H$ (Eq. (1.264)), and the Co3d 4 s HO has an energy of $E(C o, 3 d 4 s)=-17.49830 \mathrm{eV}$ (Eq. (23.144)). To meet the equipotential condition of the union of the $C o-L H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor(s), at least one of $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $C o-L$-bond MO given by Eq. (15.77) is:

$$
\begin{align*}
& c_{2}(F A O \text { to Co3d } 4 \mathrm{sHO})=\frac{E(F A O)}{E(C o, 3 d 4 s)}=\frac{-17.42282 \mathrm{eV}}{-17.49830 \mathrm{eV}}=0.99569  \tag{23.151}\\
& C_{2}(\mathrm{ClAO} \text { to Co3d } 4 \mathrm{sHO})=\frac{E(C l A O)}{E(C o, 3 d 4 s)}=\frac{-12.96764 \mathrm{eV}}{-17.49830 \mathrm{eV}}=0.74108  \tag{23.152}\\
& c_{2}\left(\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO} \text { to } \mathrm{Co} 3 \mathrm{~d} 4 \mathrm{sHO}\right)=\frac{E\left(\mathrm{C}, 2 s p^{3}\right)}{E_{\text {Coulomb }}(\mathrm{Co}, 3 d 4 \mathrm{~s})} c_{2}\left(\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO}\right)=\frac{-14.63489 \mathrm{eV}}{-16.97989 \mathrm{eV}}(0.91771)=0.79097  \tag{23.153}\\
& c_{2}(\mathrm{HAO} \text { to Co3d } 4 \mathrm{sHO})=\mathrm{C}_{2}(\mathrm{HAO} \text { to } \mathrm{Co} 3 d 4 \mathrm{sHO})=\frac{E(\mathrm{H})}{E_{\text {Coulomb }}(\mathrm{Co}, 3 d 4 \mathrm{~s})}=\frac{-13.605804 \mathrm{eV}}{-16.97989 \mathrm{eV}}=0.80129 \tag{23.154}
\end{align*}
$$

where Eqs. (15.76), (15.79), and (13.430) were used in Eq. (23.152) and Eq. (15.71) was used in Eq. (23.153). Since the energy of the MO is matched to that of the $\mathrm{Co} 3 d 4 s \mathrm{HO}$ in coordinate compounds, $E(A O / H O)$ in Eq. (15.61) is $E(C o, 3 d 4 s)$ given by Eq. (23.144) and $E(A O / H O)$ in Eq. (15.61) of carbonyl compounds is $E_{\text {Coulomb }}(C o, 3 d 4 s)$ given by Eq. (23.138). $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C o-L$-bond MO is determined by considering that the bond involves an electron transfer from the cobalt atom to the ligand atom to form partial ionic character in the bond as in the case of the zwitterions such as $H_{2} B^{+}-F^{-}$given in the Halido Boranes section. For the coordinate compounds, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -1.20896 eV , two times the energy of Eq. (23.149). For the $C o-C$ bonds of carbonyl compounds, $E_{T}\left(\right.$ atom-atom, msp $\left.{ }^{3} . A O\right)$ is -1.13379 eV (Eq. (14.247)), and the $C=O$ functional group of carbonyls is equivalent to that of vanadium carbonyls.

The symbols of the functional groups of cobalt coordinate compounds are given in Table 23.40. The geometrical (Eqs. (15.1-15.5) and (23.41)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of cobalt coordinate compounds are given in Tables 23.41, 23.42, and 23.43, respectively. The total energy of each cobalt coordinate compound given in Table 23.44 was calculated as the sum over the integer multiple of each $E_{D}$ ( Group) of Table 23.43 corresponding to functional-group composition of the compound. The charge-densities of exemplary cobalt carbonyl compound, cobalt tetracarbonyl hydride $\left(\mathrm{CoH}(\mathrm{CO})_{4}\right)$ comprising the concentric shells of atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 23.9.

Figure 23.9. Cobalt Tetracarbonyl Hydride. Color scale, translucent view of the charge-density of $\mathrm{CoH}(\mathrm{CO})_{4}$ showing the orbitals of the $C o, C$, and $O$ atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale).

## NICKEL FUNCTIONAL GROUPS AND MOLECULES

The electron configuration of nickel is $[A r] 4 s^{2} 3 d^{8}$ having the corresponding term ${ }^{3} F_{4}$. The total energy of the state is given by the sum over the ten electrons. The sum $E_{T}(N i, 3 d 4 s)$ of experimental energies [1] of $N i, N i^{+}, N i^{2+}, N i^{3+}, N i^{4+}, N i^{5+}, N i^{6+}$, $N i^{7+}, \mathrm{Ni}^{8+}$, and $\mathrm{Ni}^{9+}$ is:

$$
\begin{equation*}
E_{T}(N i, 3 d 4 s)=-\binom{224.6 \mathrm{eV}+193 \mathrm{eV}+162 \mathrm{eV}+133 \mathrm{eV}+108 \mathrm{eV}+76.06 \mathrm{eV}}{+54.9 \mathrm{eV}+35.19 \mathrm{eV}+18.16884 \mathrm{eV}+7.6398 \mathrm{eV}}=-1012.55864 \mathrm{eV} \tag{23.155}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 d 4 s}$ of the $N i 3 d 4 s$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{3 d 4 s}=\sum_{n=18}^{27} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 1012.55864 \mathrm{eV})}=\frac{55 e^{2}}{8 \pi \varepsilon_{0}(e 1012.55864 \mathrm{eV})}=0.73904 a_{0} \tag{23.156}
\end{equation*}
$$

where $Z=28$ for nickel. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}(N i, 3 d 4 s)$ of the outer electron of the $N i 3 d 4 s$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}(N i, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.73904 a_{0}}=-18.410157 \mathrm{eV} \tag{23.157}
\end{equation*}
$$

During hybridization, the spin-paired $4 s$ electrons and the three sets of paired $3 d$ electrons are promoted to the $N i 3 d 4 s$ shell as initially unpaired electrons. The energies for the promotions are given by Eq. (15.15) at the initial radii of the $4 s$ and $3 d$ electrons. From Eq. (10.102) with $Z=28$ and $n=28$, the radius $r_{28}$ of the Ni4s shell is

$$
\begin{equation*}
r_{28}=1.78091 a_{0} \tag{23.158}
\end{equation*}
$$

and with $Z=28$ and $n=26$, the radius $r_{26}$ of the Ni3d shell is:

$$
\begin{equation*}
r_{26}=1.15992 a_{0} \tag{23.159}
\end{equation*}
$$

Using Eqs. (15.15), (23.157), and (23.158), the unpairing energies are:

$$
\begin{align*}
& E_{4 s}(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{28}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(1.78091 a_{0}\right)^{3}}=0.02026 \mathrm{eV}  \tag{23.160}\\
& E_{3 d}(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{26}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(1.15992 a_{0}\right)^{3}}=0.07331 \mathrm{eV} \tag{23.161}
\end{align*}
$$

The electrons from the $4 s$ and $3 d$ shells successively fill unoccupied HOs until the HO shell is filled with unpaired electrons, then the electrons pair per HO. In the case of the Ni3d4s shell having ten electrons and six orbitals, four sets of electrons are paired. Using Eqs. (15.15) and (23.155), the pairing energy is given by:

$$
\begin{equation*}
E_{3 d 4 s}(\text { magnetic })=-\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3 d 4 s}\right)^{3}}=-\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.73904 a_{0}\right)^{3}}=-0.28344 \mathrm{eV} \tag{23.162}
\end{equation*}
$$

Thus, after Eq. (23.28), the energy $E(N i, 3 d 4 s)$ of the outer electron of the $N i 3 d 4 s$ shell is given by adding the magnetic energies of unpairing the $4 s$ (Eq. (23.159)) and $3 d$ electrons (Eq. (23.160)) and pairing of four sets of $N i 3 d 4 s$ electrons (Eq. (23.161)) to $E_{\text {Coulomb }}(N i, 3 d 4 s)$ (Eq. (23.156)).

$$
\begin{align*}
E(N i, 3 d 4 s) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{4 s}^{3}}+\sum_{3 d \text { pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d}^{3}}-\sum_{H O \text { pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d 4 s}^{3}}  \tag{23.163}\\
& =-18.410157 \mathrm{eV}+0.02026 \mathrm{eV}+3(0.07331 \mathrm{eV})-4(0.28344 \mathrm{eV})=-19.30374 \mathrm{eV}
\end{align*}
$$

Next, consider the formation of the $N i-L$-bond MO wherein each nickel atom has a $N i 3 d 4 s$ electron with an energy given by Eq. (23.162). The total energy of the state of each nickel atom is given by the sum over the ten electrons. The sum $E_{T}\left(N i_{N i-L} 3 d 4 s\right)$ of energies of $N i 3 d 4 s$ (Eq. (23.162)), $N i^{+}, N i^{2+}, N i^{3+}, N i^{4+}, N i^{5+}, N i^{6+}, N i^{7+}, N i^{8+}$, and $N i^{9+}$ is:

$$
\begin{align*}
E_{T}\left(N i_{N i-L} 3 d 4 s\right) & =-\binom{224.6 \mathrm{eV}+193 \mathrm{eV}+162 \mathrm{eV}+133 \mathrm{eV}+108 \mathrm{eV}+76.06 \mathrm{eV}}{+54.9 \mathrm{eV}+35.19 \mathrm{eV}+18.16884 \mathrm{eV}+E(N i, 3 \mathrm{~d} 4 \mathrm{~s})}  \tag{23.164}\\
& =-\binom{224.6 \mathrm{eV}+193 \mathrm{eV}+162 \mathrm{eV}+133 \mathrm{eV}+108 \mathrm{eV}+76.06 \mathrm{eV}}{+54.9 \mathrm{eV}+35.19 \mathrm{eV}+18.16884 \mathrm{eV}+19.30374 \mathrm{eV}}=-1024.22258 \mathrm{eV}
\end{align*}
$$

where $E(N i, 3 d 4 s)$ is the sum of the energy of $N i,-7.6398 \mathrm{eV}$, and the hybridization energy.
The nickel HO donates an electron to each MO. Using Eq. (23.30), the radius $r_{3 d 4 s}$ of the $N i 3 d 4 s$ shell calculated from the Coulombic energy is:

$$
\begin{equation*}
r_{N i-L 3 d 4 s}=\left(\sum_{n=18}^{27}(Z-n)-1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 1024.22258 \mathrm{eV})}=\frac{54 e^{2}}{8 \pi \varepsilon_{0}(e 1024.22258 \mathrm{eV})}=0.71734 a_{0} \tag{23.165}
\end{equation*}
$$

Using Eqs. (15.19) and (23.164), the Coulombic energy $E_{\text {Coulomb }}\left(N i_{N i-L}, 3 d 4 s\right)$ of the outer electron of the $N i 3 d 4 s$ shell is

$$
\begin{equation*}
E_{\text {Coulomb }}\left(N i_{N i-L}, 3 d 4 s\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{N i-L 3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.71734 a_{0}}=-18.96708 \mathrm{eV} \tag{23.166}
\end{equation*}
$$

The magnetic energy terms are those for the unpairing of the $4 s$ and $3 d$ electrons (Eqs. (23.159) and (23.160), respectively) and paring four sets of $N i 3 d 4 s$ electrons (Eq. (23.161)). Using Eqs. (23.32), (23.165) and (23.159-23.161), the energy $E\left(N i_{N i-L}, 3 d 4 s\right)$ of the outer electron of the $N i 3 d 4 s$ shell is:

$$
\begin{align*}
E\left(N i_{N i-L}, 3 d 4 s\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{N i-L 3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{28}\right)^{3}}+3 \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{26}\right)^{3}}-4 \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3 d 4 s}\right)^{3}}  \tag{23.167}\\
& =-18.96708 \mathrm{eV}+0.02026 \mathrm{eV}+3(0.07331 \mathrm{eV})-4(0.28344 \mathrm{eV})=-19.86066 \mathrm{eV}
\end{align*}
$$

Thus, $E_{T}(N i-L, 3 d 4 s)$, the energy change of each $N i 3 d 4 s$ shell with the formation of the $N i-L$-bond MO is given by the difference between Eq. (23.166) and Eq. (23.162):

$$
\begin{equation*}
E_{T}(N i-L, 3 d 4 s)=E\left(N i_{N i-L}, 3 d 4 s\right)-E(N i, 3 d 4 s)=-19.86066 \mathrm{eV}-(-19.30374 \mathrm{eV})=-0.55693 \mathrm{eV} \tag{23.168}
\end{equation*}
$$

The semimajor axis $a$ solution given by Eq. (23.41) of the force balance equation, Eq. (23.39), for the $\sigma$-MO of the $\mathrm{Ni}-L$-bond MO of $\mathrm{NiL}_{n}$ is given in Table 23.46 with the force-equation parameters $Z=28, n_{e}$, and $L$ corresponding to the orbital and spin angular momentum terms of the $3 d 4 s \mathrm{HO}$ shell. The semimajor axis $a$ of carbonyl and organometallic compounds are solved using Eq. (15.51).

For the $N i-L$ functional groups, hybridization of the $4 s$ and $3 d$ AOs of $N i$ to form a single $3 d 4 s$ shell forms an energy minimum, and the sharing of electrons between the $N i 3 d 4 s$ HO and $L$ AO to form a MO permits each participating orbital to decrease in radius and energy. The Cl AO has an energy of $E(\mathrm{Cl})=-12.96764 \mathrm{eV}$, the $C_{\text {aryl }} 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C_{\text {aryl }}, 2 s p^{3}\right)=-15.76868 \mathrm{eV}$ (Eq. (14.246)), the $C 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), the Coulomb energy of $N i 3 d 4 s$ HO is $E_{\text {Coulomb }}(N i, 3 d 4 s)=-18.41016 \mathrm{eV}$ (Eq. (23.156)), and the $N i 3 d 4 s$ HO has an energy of $E(N i, 3 d 4 s)=-19.30374 \mathrm{eV}$ (Eq. (23.162)). To meet the equipotential condition of the union of the $N i-L H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor(s), at least one of $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $N i-L$-bond MO given by Eq. (15.77) is:

$$
\begin{align*}
& C_{2}(C l A O \text { to Ni3d } 4 s H O)=\frac{E(C l A O)}{E(N i, 3 d 4 s)}=\frac{-12.96764 \mathrm{eV}}{-19.30374 \mathrm{eV}}=0.67177  \tag{23.169}\\
& c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Ni} 3 d 4 s \mathrm{HO}\right)=\frac{E\left(C, 2 s p^{3}\right)}{E_{\text {Coulomb }}(N i, 3 d 4 s)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-14.63489 \mathrm{eV}}{-18.41016 \mathrm{eV}}(0.91771)=0.72952  \tag{23.170}\\
& C_{2}\left(C_{\text {aryl }} 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Ni} 3 d 4 s H O\right)=\frac{E\left(C, 2 s p^{3}\right)}{E_{\text {Coulomb }}(N i, 3 d 4 s)} c_{2}\left(C_{\text {aryl }} 2 s p^{3} \mathrm{HO}\right)=\frac{-14.63489 \mathrm{eV}}{-18.41016 \mathrm{eV}}(0.85252)=0.67770 \tag{23.171}
\end{align*}
$$

where Eqs. (15.76), (15.79), and (13.430) were used in Eq. (23.169) and Eqs. (15.76), (15.79), and (14.417) were used in Eq. (23.170). Since the energy of the MO is matched to that of the $N i 3 d 4 s$ HO in coordinate compounds, $E(A O / H O)$ in Eq. (15.61) is $E(N i, 3 d 4 s)$ given by Eq. (23.162) and $E(A O / H O)$ in Eq. (15.61) of carbonyl compounds and organometallics is $E_{\text {Coulomb }}(N i, 3 d 4 s)$ given by Eq. (23.156). $\quad E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $N i-L$-bond MO is determined by considering that the bond involves an electron transfer from the nickel atom to the ligand atom to form partial ionic character in the bond as in the case of the zwitterions such as $\mathrm{H}_{2} \mathrm{~B}^{+}-\mathrm{F}^{-}$given in the Halido Boranes section. For the coordinate compounds, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -1.11386 eV , two times the energy of Eq. (23.167). For the $N i-C$ bonds of carbonyl compound, $\mathrm{Ni}(\mathrm{CO})_{4}$ and organometallic, nickelocene, $E_{T}\left(\right.$ atom-atom, $\left.m \mathrm{mp}^{3} . \mathrm{AO}\right)$ is -1.85837 eV (two times Eq. (14.513)) and -0.92918 eV (Eq. (14.513)), respectively. The $\mathrm{C}=\mathrm{O}$ functional group of $\mathrm{Ni}(\mathrm{CO})_{4}$ is equivalent to that of vanadium carbonyls. The aromatic cyclopentadienyl moieties of organometallic $\mathrm{Ni}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2}$ comprise $\mathrm{C} \stackrel{3 e}{=} \mathrm{C}$ and CH functional groups that are equivalent to those given in the Aromatic and Heterocyclic Compounds section.

The symbols of the functional groups of nickel coordinate compounds are given in Table 23.45. The geometrical (Eqs. (15.1-15.5) and (23.41)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of nickel coordinate compounds are given in Tables 23.46, 23.47, and 23.48, respectively. The total energy of each nickel coordinate compound given in Table 23.49 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table
23.48 corresponding to functional-group composition of the compound. The charge-densities of exemplary nickel carbonyl and organometallic compounds, nickel tetracarbonyl $\left(\mathrm{Ni}(\mathrm{CO})_{4}\right)$ and bis-cylopentadienyl nickel or nickelocene $\left(\mathrm{Ni}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2}\right)$ comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figure 23.10A and B, respectively.

Figure 23.10. (A) Nickel Tetracarbonyl. Color scale, translucent view of the charge-density of $\mathrm{Ni}(\mathrm{CO})_{4}$ showing the orbitals of the $\mathrm{Ni}, \mathrm{C}$, and O atoms at their radii, the ellipsoidal surface of each $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale). (B) Nickelocene. Color scale, opaque view of the charge-density of $\mathrm{Ni}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2}$ showing the orbitals of the Ni and C atoms at their radii and the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond.

Table 23.45. The symbols of the functional groups of nickel coordinate compounds.

| Functional Group | Group Symbol |
| :--- | :--- |
| NiCl group of NiCl | $\mathrm{Ni}-\mathrm{Cl}$ (a) |
| $\mathrm{NiCl}_{2}$ group of NiCl | 2 |

## COPPER FUNCTIONAL GROUPS AND MOLECULES

The electron configuration of copper is $[A r] 4 s^{1} 3 d^{10}$ having the corresponding term ${ }^{2} S_{1 / 2}$. The single outer $4 s$ [61] electron having an energy of -7.72638 eV [1] forms a single bond to give an electron configuration with filled $3 d$ and $4 s$ shells. Additional bonding of copper is possible involving a double bond or two single bonds by the hybridization of the $3 d$ and $4 s$ shells to form a $C u 3 d 4 s$ shell and the donation of an electron per bond. The total energy of the copper ${ }^{2} S_{1 / 2}$ state is given by the sum over the eleven electrons. The sum $E_{T}(\mathrm{Cu}, 3 d 4 s)$ of experimental energies [1] of $\mathrm{Cu}, \mathrm{Cu}^{+}, \mathrm{Cu}^{2+}, \mathrm{Cu}^{3+}, \mathrm{Cu}^{4+}, \mathrm{Cu}^{5+}$, $\mathrm{Cu}^{6+}, \mathrm{Cu}^{7+}, \mathrm{Cu}^{8+}, \mathrm{Cu}^{9+}$, and $\mathrm{Cu}^{10+}$ is

$$
\begin{equation*}
E_{T}(C u, 3 d 4 s)=-\binom{265.3 \mathrm{eV}+232 \mathrm{eV}+199 \mathrm{eV}+166 \mathrm{eV}+139 \mathrm{eV}+103 \mathrm{eV}+79.8 \mathrm{eV}}{+57.38 \mathrm{eV}+36.841 \mathrm{eV}+20.2924 \mathrm{eV}+7.72638 \mathrm{eV}}=-1306.33978 \mathrm{eV} \tag{23.172}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 d 4 s}$ of the $C u 3 d 4 s$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{3 d 4 s}=\sum_{n=18}^{28} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 1306.33978 \mathrm{eV})}=\frac{66 e^{2}}{8 \pi \varepsilon_{0}(\mathrm{e} 1306.33978 \mathrm{eV})}=0.68740 a_{0} \tag{23.173}
\end{equation*}
$$

where $Z=29$ for copper. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}(C u, 3 d 4 s)$ of the outer electron of the $C u 3 d 4 s$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}(C u, 3 d 4 s)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.68740 a_{0}}=-19.793027 \mathrm{eV} \tag{23.174}
\end{equation*}
$$

During hybridization, the unpaired $4 s$ electron and five sets of spin-paired $3 d$ electrons are promoted to the $C u 3 d 4 s$ shell as initially unpaired electrons. The energies for the promotions of the initially paired electrons are given by Eq. (15.15) at the initial radius of the $3 d$ electrons. From Eq. (10.102) with $Z=29$ and $n=28$, the radius $r_{28}$ of the $C u 3 d$ shell is:

$$
\begin{equation*}
r_{28}=1.34098 a_{0} \tag{23.175}
\end{equation*}
$$

Using Eqs. (15.15), and (23.174), the unpairing energy is:

$$
\begin{equation*}
E_{3 d}(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{28}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(1.34098 a_{0}\right)^{3}}=0.04745 \mathrm{eV} \tag{23.176}
\end{equation*}
$$

The electrons from the $4 s$ and $3 d$ shells successively fill unoccupied HOs until the HO shell is filled with unpaired electrons, then the electrons pair per HO. In the case of the Cu3d $4 s$ shell having eleven electrons and six orbitals, five sets of electrons are paired. Using Eqs. (15.15) and (23.172), the pairing energy is given by:

$$
\begin{equation*}
E_{3 d 4 s}(\text { magnetic })=-\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3 d 4 s}\right)^{3}}=-\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.68740 a_{0}\right)^{3}}=-0.35223 \mathrm{eV} \tag{23.177}
\end{equation*}
$$

Thus, after Eq. (23.28), the energy $E(C u, 3 d 4 s)$ of the outer electron of the $C u 3 d 4 s$ shell is given by adding the magnetic energies of unpairing five sets of $3 d$ electrons (Eq. (23.175)) and pairing of five sets of Cu3d4s electrons (Eq. (23.176)) to $E_{\text {Coulomb }}(C u, 3 d 4 s)$ (Eq. (23.173)).

$$
\begin{align*}
E(C u, 3 d 4 s) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 d 4 s}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{4 s}^{3}}+\sum_{3 d \text { pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d}^{3}}-\sum_{H O \text { pairs }} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{3 d 4 s}^{3}}  \tag{23.178}\\
& =-19.793027 \mathrm{eV}+0 \mathrm{eV}+5(0.04745 \mathrm{eV})-5(0.35223 \mathrm{eV})=-21.31697 \mathrm{eV}
\end{align*}
$$

Next, consider the formation of the $C u-L$-bond MO wherein each copper atom has a $C u 3 d 4 s$ electron with an energy given by Eq. (23.178). The total energy of the state of each copper atom is given by the sum over the eleven electrons. The sum $E_{T}\left(C u_{C u-L} 3 d 4 s\right)$ of energies of $\mathrm{Cu} 3 \mathrm{~d} 4 s$ (Eq. (23.178)), $\mathrm{Cu}^{+}, \mathrm{Cu}^{2+}, \mathrm{Cu}^{3+}, \mathrm{Cu}^{4+}, \mathrm{Cu}^{5+}, \mathrm{Cu}^{6+}, \mathrm{Cu}^{7+}, \mathrm{Cu}^{8+}, \mathrm{Cu}^{9+}$, and $\mathrm{Cu}^{10+}$ is:

$$
\begin{align*}
E_{T}\left(C u_{C u-L} 3 d 4 s\right) & =-\left(\begin{array}{l}
265.3 \mathrm{eV}+232 \mathrm{eV}+199 \mathrm{eV}+166 \mathrm{eV} \\
+139 \mathrm{eV}+103 \mathrm{eV}+79.8 \mathrm{eV}+57.38 \mathrm{eV} \\
+36.841 \mathrm{eV}+20.2924 \mathrm{eV}+E(C u, 3 d 4 \mathrm{~s})
\end{array}\right)  \tag{23.179}\\
& =-\left(\begin{array}{l}
265.3 \mathrm{eV}+232 \mathrm{eV}+199 \mathrm{eV}+166 \mathrm{eV} \\
+139 \mathrm{eV}+103 \mathrm{eV}+79.8 \mathrm{eV}+57.38 \mathrm{eV} \\
+36.841 \mathrm{eV}+20.2924 \mathrm{eV}+21.31697 \mathrm{eV}
\end{array}\right)=-1319.93037 \mathrm{eV}
\end{align*}
$$

where $E(C u, 3 d 4 s)$ is the sum of the energy of $C u,-7.72638 \mathrm{eV}$, and the hybridization energy.
The copper HO donates an electron to each MO. Using Eq. (23.30), the radius $r_{3 d 4 s}$ of the $\mathrm{Cu} 3 d 4 s$ shell calculated from the Coulombic energy is:

$$
\begin{equation*}
r_{C u-L 344 s}=\left(\sum_{n=18}^{28}(Z-n)-1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 1319.93037 \mathrm{eV})}=\frac{65 e^{2}}{8 \pi \varepsilon_{0}(e 1319.93037 \mathrm{eV})}=0.67002 a_{0} \tag{23.180}
\end{equation*}
$$

Using Eqs. (15.19) and (23.179), the Coulombic energy $E_{\text {Coulomb }}\left(C_{C u-L}, 3 d 4 s\right)$ of the outer electron of the $C u 3 d 4 s$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb } b}\left(C u_{C u-L}, 3 d 4 s\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{C u-L 3 d 4 s}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.67002 a_{0}}=-20.30662 \mathrm{eV} \tag{23.181}
\end{equation*}
$$

The magnetic energy terms are those for the unpairing of the five sets of $3 d$ electrons (Eq. (23.175)) and pairing of five sets of $C u 3 d 4 s$ electrons (Eq. (23.176)). Using Eqs. (23.32), (23.180), and (23.175-23.176), the energy $E\left(C u_{C u-L}, 3 d 4 s\right)$ of the outer electron of the Cu $3 d 4 s$ shell is:

$$
\begin{align*}
E\left(C u_{C u-L}, 3 d 4 s\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} C_{u-L 3 d 4 s}}+0 \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{29}\right)^{3}}+5 \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{28}\right)^{3}}-5 \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3 d s}\right)^{3}}  \tag{23.182}\\
& =-20.30662 \mathrm{eV}+0 \mathrm{eV}+5(0.04745 \mathrm{eV})-5(0.35223 \mathrm{eV})=-21.83056 \mathrm{eV}
\end{align*}
$$

Thus, $E_{T}(\mathrm{Cu}-L, 3 d 4 s)$, the energy change of each $\mathrm{Cu} 3 d 4 s$ shell with the formation of the $\mathrm{Cu}-L$-bond MO is given by the difference between Eq. (23.181) and Eq. (23.177).

$$
\begin{equation*}
E_{T}(C u-L, 3 d 4 s)=E\left(C u_{C u-L}, 3 d 4 s\right)-E(C u, 3 d 4 s)=-21.83056 \mathrm{eV}-(-21.31697 \mathrm{eV})=-0.51359 \mathrm{eV} \tag{23.183}
\end{equation*}
$$

The semimajor axis $a$ solution given by Eq. (23.41) of the force balance equation, Eq. (23.39), for the $\sigma$-MO of the $C u-L$-bond MO of $C u L_{n}$ is given in Table 23.51 with the force-equation parameters $Z=29, n_{e}$, and $L$ corresponding to the orbital and spin angular momentum terms of the $3 d 4 s \mathrm{HO}$ shell.

For the $C u-L$ functional groups, hybridization of the $4 s$ and $3 d$ AOs of $C u$ to form a single $3 d 4 s$ shell forms an energy minimum, and the sharing of electrons between the $\mathrm{Cu} 3 d 4 s \mathrm{HO}$ and $L \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. The $F \mathrm{AO}$ has an energy of $E(F)=-17.42282 \mathrm{eV}$, the Cl AO has an energy of $E(C l)=-12.96764 \mathrm{eV}$, the $O \mathrm{AO}$ has an energy of $E(O)=-13.61805 \mathrm{eV}$, the Cu AO has an energy of $E(C u)=-7.72638 \mathrm{eV}$, and the $C u 3 d 4 s$ HO has an energy of $E(C u, 3 d 4 s)=-21.31697 \mathrm{eV}$ (Eq. (23.177)). To meet the equipotential condition of the union of the $\mathrm{Cu}-L \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor(s), at least one of $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $C u-L$-bond MO given by Eq. (15.77) is:

$$
\begin{align*}
& C_{2}(F A O \text { to } C u A O)=\frac{E(C u A O)}{E(F A O)}=\frac{-7.72638 \mathrm{eV}}{-17.42282 \mathrm{eV}}=0.44346  \tag{23.184}\\
& c_{2}(C l A O \text { to } C u A O)=C_{2}(C l A O \text { to } C u A O)=\frac{E(C u A O)}{E(C l A O)}=\frac{-7.72638 \mathrm{eV}}{-12.96764 \mathrm{eV}}=0.59582  \tag{23.185}\\
& C_{2}(F A O \text { to } C u 3 d 4 \mathrm{sHO})=\frac{E(F A O)}{E(C u, 3 d 4 \mathrm{~s})}=\frac{-17.42282 \mathrm{eV}}{-21.31697 \mathrm{eV}}=0.81732  \tag{23.186}\\
& c_{2}(O \text { to } C u 3 d 4 \mathrm{sHO})=\frac{E(O)}{E(C u, 3 d 4 \mathrm{~s})}=\frac{-13.61805 \mathrm{eV}}{-21.31697 \mathrm{eV}}=0.63884 \tag{23.187}
\end{align*}
$$

Since the energy of the MO is matched to that of the Cu3d4s HO in coordinate compounds, $E(A O / H O)$ in Eq. (15.61) is $E(C u, 3 d 4 s)$ given by Eq. (23.177) and twice this value for double bonds. $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ of the $C u-L$-bond MO is determined by considering that the bond involves an electron transfer from the copper atom to the ligand atom to form partial ionic character in the bond as in the case of the zwitterions such as $H_{2} B^{+}-F^{-}$given in the Halido Boranes section. For the twobond coordinate compounds, $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ is -1.02719 eV , two times the energy of Eq. (23.182).

The symbols of the functional groups of copper coordinate compounds are given in Table 23.50. The geometrical (Eqs. (15.1-15.5) and (23.41)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of copper coordinate compounds are given in Tables 23.51, 23.52, and 23.53, respectively. The total energy of each copper coordinate compound given in Table 23.54 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 23.53 corresponding to functional-group composition of the compound. The charge-densities of exemplary copper coordinate compounds, copper chloride ( CuCl ) and copper dichloride $\left(\mathrm{CuCl}_{2}\right)$ comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 23.11A and $B$, respectively.

Figure 23.11. (A) Copper Chloride. Color scale, translucent view of the charge-density of CuCl showing the orbitals of the Cu and Cl atoms at their radii, the ellipsoidal surface of each $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale). (B) Copper Dichloride. Color scale, translucent view of the charge-density of $\mathrm{CuCl}_{2}$ showing the orbitals of the Cu and Cl atoms at their radii, the ellipsoidal surface of each $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale).

## ZINC FUNCTIONAL GROUPS AND MOLECULES

The electron configuration of zinc is $[A r] 4 s^{2} 3 d^{10}$ having the corresponding term ${ }^{1} S_{0}$. The two outer $4 s$ [61] electrons having energies of -9.394199 eV and -17.96439 eV [1] hybridize to form a single shell comprising two HOs. Each HO donates an electron to any single bond that participates in bonding with the HO such that two single bonds with ligands are possible to achieve a filled, spin-paired outer electron shell. Then, the total energy of the ${ }^{1} S_{0}$ state of the bonding zinc atom is given by the sum over the two electrons. The sum $E_{T}(Z n, 4 s H O)$ of experimental energies [1] of Zn , and $\mathrm{Zn}^{+}$, is:

$$
\begin{equation*}
E_{T}(Z n, 4 s H O)=-(17.96439 \mathrm{eV}+9.394199 \mathrm{eV})=-27.35859 \mathrm{eV} \tag{23.188}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{4 s H O}$ of the $Z n 4 s$ HO shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{4 s H O}=\sum_{n=28}^{29} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 27.35859 \mathrm{eV})}=\frac{3 e^{2}}{8 \pi \varepsilon_{0}(e 27.35859 \mathrm{eV})}=1.49194 a_{0} \tag{23.189}
\end{equation*}
$$

where $Z=30$ for zinc. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}(Z n, 4 s H O)$ of the outer electron of the $Z n 4 s$ shell is

$$
\begin{equation*}
E_{\text {Coulomb }}(Z n, 4 s H O)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{4 s H O}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.49194 a_{0}}=-9.119530 \mathrm{eV} \tag{23.190}
\end{equation*}
$$

During hybridization, the spin-paired $4 s \mathrm{AO}$ electrons are promoted to the $\mathrm{Zn} 4 s \mathrm{HO}$ shell as unpaired electrons. The energy for the promotion is given by Eq. (15.15) at the initial radius of the $4 s$ electrons. From Eq. (10.102) with $Z=30$ and $n=30$, the radius $r_{30}$ of the $Z n 4 s \mathrm{AO}$ shell is:

$$
\begin{equation*}
r_{30}=1.44832 a_{0} \tag{23.191}
\end{equation*}
$$

Using Eqs. (15.15) and (23.190), the unpairing energy is:

$$
\begin{equation*}
E_{4 s}(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{30}\right)^{3}}=\frac{8 \pi \mu_{o} \mu_{B}^{2}}{\left(1.44832 a_{0}\right)^{3}}=0.03766 \mathrm{eV} \tag{23.192}
\end{equation*}
$$

Using Eqs. (23.189) and (23.191), the energy $E(\mathrm{Zn}, 4 s \mathrm{HO})$ of the outer electron of the Zn 4 s HO shell is:

$$
\begin{equation*}
E(Z n, 4 s H O)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{4 s H O}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{30}\right)^{3}}=-9.119530 \mathrm{eV}+0.03766 \mathrm{eV}=-9.08187 \mathrm{eV} \tag{23.193}
\end{equation*}
$$

Next, consider the formation of the $\mathrm{Zn}-L$-bond MO wherein each zinc atom has a $\mathrm{Zn} 4 s \mathrm{HO}$ electron with an energy given by Eq. (23.192). The total energy of the state of each zinc atom is given by the sum over the two electrons. The sum $E_{T}\left(\mathrm{Zn}_{Z n-L} 4 s \mathrm{HO}\right)$ of energies of $\mathrm{Zn} 4 s \mathrm{HO}$ (Eq. (23.192)) and $\mathrm{Zn}^{+}$is:

$$
\begin{equation*}
E_{T}\left(Z n_{Z n-L} 4 s H O\right)=-(17.96439 \mathrm{eV}+E(Z n, 4 s H O))=-(17.96439 \mathrm{eV}+9.08187 \mathrm{eV})=-27.04626 \mathrm{eV} \tag{23.194}
\end{equation*}
$$

where $E(Z n, 4 s H O)$ is the sum of the energy of $Z n,-9.394199 \mathrm{eV} \mathrm{eV}$, and the hybridization energy.
The zinc HO donates an electron to each MO. Using Eq. (23.30), the radius $r_{4 s H O}$ of the $\mathrm{Zn} 4 s \mathrm{HO}$ shell calculated from the Coulombic energy is:

$$
\begin{equation*}
r_{\text {Zn-L4sHO }}=\left(\sum_{n=28}^{29}(Z-n)-1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 27.04626 \mathrm{eV})}=\frac{2 e^{2}}{8 \pi \varepsilon_{0}(e 27.04626 \mathrm{eV})}=1.00611 a_{0} \tag{23.195}
\end{equation*}
$$

Using Eqs. (15.19) and (23.194), the Coulombic energy $E_{\text {Coulomb }}\left(Z n_{Z n-L}, 4 s H O\right)$ of the outer electron of the Zn 4 sHO shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(Z n_{Z n-L}, 4 s H O\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{Z n-L 4 s H O}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.00611 a_{0}}=-13.52313 \mathrm{eV} \tag{23.196}
\end{equation*}
$$

During hybridization, the spin-paired $2 s$ electrons are promoted to the Zn 4 sHO shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (23.191). Using Eqs. (23.195) and (23.191), the energy $E\left(Z n_{Z n-L}, 4 s H O\right)$ of the outer electron of the $\mathrm{Zn} 4 s \mathrm{HO}$ shell is:

$$
\begin{equation*}
E\left(Z n_{Z n-L}, 4 s H O\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{Z n-L 4 s H O}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{30}\right)^{3}}=-13.52313 \mathrm{eV}+0.03766 \mathrm{eV}=-13.48547 \mathrm{eV} \tag{23.197}
\end{equation*}
$$

Thus, $E_{T}(\mathrm{Zn}-L, 4 s H O)$, the energy change of each $\mathrm{Zn} 4 s \mathrm{HO}$ shell with the formation of the $\mathrm{Zn}-L$-bond MO is given by the difference between Eq. (23.196) and Eq. (23.192):

$$
\begin{equation*}
E_{T}(Z n-L, 4 s H O)=E\left(Z n_{Z n-L}, 4 s H O\right)-E(Z n, 4 s H O)=-13.48547 \mathrm{eV}-(-9.08187 \mathrm{eV})=-4.40360 \mathrm{eV} \tag{23.198}
\end{equation*}
$$

The semimajor axis $a$ solution given by Eq. (23.41) of the force balance equation, Eq. (23.39), for the $\sigma$-MO of the $Z n-L$-bond MO of $Z n L_{n}$ is given in Table 23.56 with the force-equation parameters $Z=30, n_{e}$, and $L$ corresponding to the orbital and spin angular momentum terms of the $4 s$ HO shell. The semimajor axis $a$ of organometallic compounds are solved using Eq. (15.51).

For the $Z n-L$ functional groups, hybridization of the $4 s$ AOs of $Z n$ to form a single $4 s$ HO shell forms an energy minimum, and the sharing of electrons between the $Z n 4 s \mathrm{HO}$ and $L \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. The Cl AO has an energy of $E(C l)=-12.96764 \mathrm{eV}$, the $C 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), the Coulomb energy of the Zn 4 s HO is $E_{\text {Coulomb }}(Z n, 4 s H O)=-9.119530 \mathrm{eV}$ (Eq. (23.189)), and the $Z n 4 s$ HO has an energy of $E(Z n, 4 s H O)=-9.08187 \mathrm{eV}$ (Eq. (23.192)). To meet the equipotential condition of the union of the $\mathrm{Zn}-\mathrm{L}_{2} \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor(s), at least one of $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $Z n-L$-bond MO given by Eq. (15.77) is:

$$
\begin{align*}
& C_{2}(\text { ClAO to } \mathrm{Zn} 4 \mathrm{sHO})=\frac{E(\mathrm{Zn}, 34 s \mathrm{HO})}{E(C l A O)}=\frac{-9.08187 \mathrm{eV}}{-12.96764 \mathrm{eV}}=0.70035  \tag{23.199}\\
& c_{2}\left(\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO} \text { to } \mathrm{Zn} 4 \mathrm{sHO}\right)=C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Zn} 4 \mathrm{sHO}\right) \\
&  \tag{23.200}\\
& =\frac{E_{\text {Coulomb }}(\mathrm{Zn}, 4 s \mathrm{HO})}{E\left(\mathrm{C}, 2 s p^{3}\right)} c_{2}\left(\mathrm{C} 2 s \mathrm{p}^{3} \mathrm{HO}\right)=\frac{-9.11953 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.57186
\end{align*}
$$

where Eqs. (15.76), (15.79), and (13.430) were used in Eq. (23.199). Since the energy of the MO is matched to that of the $\mathrm{Zn} 4 s \mathrm{HO}$ in coordinate compounds, $E(\mathrm{AO} / \mathrm{HO})$ in Eq. (15.61) is $E(\mathrm{Zn}, 4 s \mathrm{HO})$ given by Eq. (23.192) and $E(\mathrm{Zn}, 4 s \mathrm{HO})$ for organometallics is $E_{\text {Coulomb }}(Z n, 4 s H O)$ given by Eq. (23.189). $\quad E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} \cdot A O\right)$ of the $Z n-L$-bond MO is determined by considering that the bond involves an electron transfer from the zinc atom to the ligand atom to form partial ionic character in the bond as in the case of the zwitterions such as $\mathrm{H}_{2} \mathrm{~B}^{+}-F^{-}$given in the Halido Boranes section. For the coordinate compounds, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -8.80720 eV , two times the energy of Eq. (23.197).

The symbols of the functional groups of zinc coordinate compounds are given in Table 23.55. The geometrical (Eqs. (15.1-15.5) and (23.41)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of zinc coordinate compounds are given in Tables 23.56, 23.57, and 23.58, respectively. The total energy of each zinc coordinate compound given in Table 22.59 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 23.58 corresponding to functional-group composition of the compound. The charge-densities of exemplary zinc coordinate and organometallic compounds, zinc chloride ( ZnCl ) and di-n-butylzinc $\left(\mathrm{Zn}\left(\mathrm{C}_{4} \mathrm{H}_{9}\right)_{2}\right)$ comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 23.12A and B, respectively.

Figure 23.12. (A) Zinc Chloride. Color scale, translucent view of the charge-density of ZnCl showing the orbitals of the Zn and Cl atoms at their radii, the ellipsoidal surface of each $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale). (B) Di-n-butylzinc. Color scale, translucent view of the charge-density of $\mathrm{Zn}\left(\mathrm{C}_{4} \mathrm{H}_{9}\right)_{2}$ showing the orbitals of the Zn and $C$ atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale).

Table 23.55. The symbols of the functional groups of zinc coordinate compounds.

| Functional Group | Group Symbol |
| :--- | :--- |

## GERMANIUM ORGANOMETALLIC FUNCTIONAL GROUPS AND MOLECULES

The branched-chain alkyl germanium molecules, $G e C_{n} H_{2 n-2}$, comprise at least one $G e$ bound by a carbon-germanium single bond comprising a $C-G e$ group, and the digermanium molecules further comprise a $G e-G e$ functional group. Both comprise at least a terminal methyl group $\left(\mathrm{CH}_{3}\right)$ and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, methylyne $(\mathrm{CH})$, and $\mathrm{C}-\mathrm{C}$ functional groups. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups.

As in the cases of carbon, silicon, and tin, the bonding in the germanium atom involves four $s p^{3}$ hybridized orbitals. For germanium, they are formed from the $4 p$ and $4 s$ electrons of the outer shells. $G e-C$ bonds form between a $G e 4 s p^{3} \mathrm{HO}$ and a $C 3 s p^{3} \mathrm{HO}$, and $G e-G e$ bonds form between between $G e 4 s p^{3}$ HOs to yield germanes and digermanes, respectively. The geometrical parameters of each $G e-C$ and $G e-G e$ functional group is solved using Eq. (15.51) and the relationships between the prolate spheroidal axes. Then, the sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the Ge4sp ${ }^{3}$ shell as in the case of the corresponding carbon, silicon, and tin molecules. As in the case of the transition metals, the energy of each functional group is determined for the effect of the electron density donation from each participating $C 3 s p^{3} \mathrm{HO}$ and $G e 4 s p^{3}$ HO to the corresponding MO that maximizes the bond energy.

The $G e$ electron configuration is $[A r] 4 s^{2} 3 d^{10} 4 p^{2}$, and the orbital arrangement is:
4 p state

$$
\begin{equation*}
\frac{\uparrow}{1} \frac{\uparrow}{0} \frac{}{-1} \tag{23.201}
\end{equation*}
$$

corresponding to the ground state ${ }^{3} P_{0}$. The energy of the germanium $4 p$ shell is the negative of the ionization energy of the germanium atom [1] given by

$$
\begin{equation*}
E(\text { Ge }, 4 p \text { shell })=-E(\text { ionization } ; G e)=-7.89943 \mathrm{eV} \tag{23.202}
\end{equation*}
$$

The energy of germanium is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264), but the atomic orbital may hybridize in order to achieve a bond at an energy minimum. After Eq. (13.422), the Ge $4 s$ atomic orbital (AO) combines with the Ge4p AOs to form a single Ge4sp hybridized orbital (HO) with the orbital arrangement:

\[

\]

where the quantum numbers $\left(\ell, m_{\ell}\right.$ ) are below each electron. The total energy of the state is given by the sum over the four electrons. The sum $E_{T}\left(G e, 4 s p^{3}\right)$ of experimental energies [1] of $G e, G e^{+}, G e^{2+}$, and $G e^{3+}$ is:

$$
\begin{equation*}
E_{T}\left(G e, 4 s p^{3}\right)=45.7131 \mathrm{eV}+34.2241 \mathrm{eV}+15.93461 \mathrm{eV}+7.89943 \mathrm{eV}=103.77124 \mathrm{eV} \tag{23.204}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{4 s p^{3}}$ of the $G e 4 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{4 s p^{3}}=\sum_{n=28}^{31} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 103.77124 \mathrm{eV})}=\frac{10 e^{2}}{8 \pi \varepsilon_{0}(e 103.77124 \mathrm{eV})}=1.31113 a_{0} \tag{23.205}
\end{equation*}
$$

where $Z=32$ for germanium. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(G e, 4 s p^{3}\right)$ of the outer electron of the $G e 4 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(G e, 4 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{4 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.31113 a_{0}}=-10.37712 \mathrm{eV} \tag{23.206}
\end{equation*}
$$

During hybridization, the spin-paired $4 s$ electrons are promoted to the $G e 4 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (15.15) at the initial radius of the $4 s$ electrons. From Eq. (10.102) with $Z=32$ and $n=30$, the radius $r_{30}$ of the Ge4s shell is:

$$
\begin{equation*}
r_{30}=1.19265 a_{0} \tag{23.207}
\end{equation*}
$$

Using Eqs. (15.15) and (23.207), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{30}\right)^{3}}=\frac{8 \pi \mu_{o} \mu_{B}^{2}}{\left(1.19265 a_{0}\right)^{3}}=0.06744 \mathrm{eV} \tag{23.208}
\end{equation*}
$$

Using Eqs. (23.206) and (23.208), the energy $E\left(G e, 4 s p^{3}\right)$ of the outer electron of the $G e 4 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(G e, 4 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{4 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{30}\right)^{3}}=-10.37712 \mathrm{eV}+0.06744 \mathrm{eV}=-10.30968 \mathrm{eV} \tag{23.209}
\end{equation*}
$$

Next, consider the formation of the $G e-L$-bond MO of gernmanium compounds wherein $L$ is a ligand including germanium and carbon and each gemanium atom has a Ge4sp electron with an energy given by Eq. (23.209). The total energy of the state of each germanium atom is given by the sum over the four electrons. The sum $E_{T}\left(G e_{G e-L}, 4 s p^{3}\right)$ of energies of $G e 4 s p^{3}$ (Eq. (23.209)), $G e^{+}, G e^{2+}$, and $G e^{3+}$ is:

$$
\begin{align*}
E_{T}\left(G e_{G e-L}, 4 s p^{3}\right) & =-\left(45.7131 \mathrm{eV}+34.2241 \mathrm{eV}+15.93461 \mathrm{eV}+E\left(G e, 4 s p^{3}\right)\right) \\
& =-(45.7131 \mathrm{eV}+34.2241 \mathrm{eV}+15.93461 \mathrm{eV}+10.30968 \mathrm{eV})  \tag{23.210}\\
& =-106.18149 \mathrm{eV}
\end{align*}
$$

where $E\left(G e, 4 s p^{3}\right)$ is the sum of the energy of $G e,-7.89943 \mathrm{eV}$, and the hybridization energy.
A minimum energy is achieved while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical ( $O H$ ) section with the donation of electron density from the participating $G e 4 s p^{3} \mathrm{HO}$ to each $G e-L$-bond MO. Consider the case wherein each $G e 4 s p^{3}$ HO donates an excess of $25 \%$ of its electron density to the $G e-L$-bond MO to form an energy minimum. By considering this electron redistribution in the germanium molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, in general terms, the radius $r_{G e-L 4 s p^{3}}$ of the $G e 4 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$
\begin{equation*}
r_{G e-L 4 s p^{3}}=\left(\sum_{n=28}^{31}(Z-n)-0.25\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 106.18149 \mathrm{eV})}=\frac{9.75 e^{2}}{8 \pi \varepsilon_{0}(\mathrm{e} 106.18149 \mathrm{eV})}=1.24934 a_{0} \tag{23.211}
\end{equation*}
$$

Using Eqs. (15.19) and (23.211), the Coulombic energy $E_{\text {Coulomb }}\left(G e_{G e-L}, 4 s p^{3}\right)$ of the outer electron of the $G e 4 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(G e_{G e-L}, 4 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{G e-L 4 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.24934 a_{0}}=-10.89041 \mathrm{eV} \tag{23.212}
\end{equation*}
$$

During hybridization, the spin-paired $4 s$ electrons are promoted to the $G e 4 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (23.208). Using Eqs. (23.208) and (23.212), the energy $E\left(G e_{G e-L}, 4 s p^{3}\right)$ of the outer electron of the Ge4sp ${ }^{3}$ shell is:

$$
\begin{equation*}
E\left(G e_{G e-L}, 4 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{G e-L 4 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{30}\right)^{3}}=-10.89041 \mathrm{eV}+0.06744 \mathrm{eV}=-10.82297 \mathrm{eV} \tag{23.213}
\end{equation*}
$$

Thus, $E_{T}\left(G e-L, 4 s p^{3}\right)$, the energy change of each $G e 4 s p^{3}$ shell with the formation of the $G e-L$-bond MO is given by the difference between Eq. (23.213) and Eq. (23.209):

$$
\begin{equation*}
E_{T}\left(G e-L, 4 s p^{3}\right)=E\left(G e_{G e-L}, 4 s p^{3}\right)-E\left(G e, 4 s p^{3}\right)=-10.82297 \mathrm{eV}-(-10.30968 \mathrm{eV})=-0.51329 \mathrm{eV} \tag{23.214}
\end{equation*}
$$

Now, consider the formation of the $G e-L$-bond MO of gernmanium compounds wherein $L$ is a ligand including germanium and carbon. For the $G e-L$ functional groups, hybridization of the $4 p$ and $4 s$ AOs of $G e$ to form a single $G e 4 s p^{3}$ HO shell forms an energy minimum, and the sharing of electrons between the Ge4sp ${ }^{3} \mathrm{HO}$ and $L$ HO to form a MO permits each participating orbital to decrease in radius and energy. The $C 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)) and the Ge4sp HO has an energy of $E\left(G e, 4 s p^{3}\right)=-10.30968 \mathrm{eV}$ (Eq. (23.209)). To meet the equipotential condition of the union of the $\mathrm{Ge}-\mathrm{L} \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $C_{2}$ of Eq. (15.61) for the $G e-L$-bond MO given by Eq. (15.77) is:

$$
\begin{equation*}
C_{2}\left(G e 4 s p^{3} \mathrm{HO} \text { to } \mathrm{Ge} 4 s p^{3} \mathrm{HO}\right)=C_{2}\left(\mathrm{C} 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Ge} 4 s p^{3} \mathrm{HO}\right)=\frac{E\left(G e, 4 s p^{3} \mathrm{HO}\right)}{E\left(C, 2 s p^{3}\right)}=\frac{-10.30968 \mathrm{eV}}{-14.63489 \mathrm{eV}}=0.70446 \tag{23.215}
\end{equation*}
$$

Since the energy of the MO is matched to that of the Ge4sp $\mathrm{HO}, E(A O / H O)$ in Eq. (15.61) is $E\left(G e, 4 s p^{3} \mathrm{HO}\right)$ given by Eq. (23.209). In order to match the energies of the HOs within the molecule, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} \cdot A O\right)$ of the $G e-L$-bond MO for the ligands carbon or germanium is $\frac{-0.72457}{2}$ (Eq. (14.151)).

The symbols of the functional groups of germanium compounds are given in Table 23.60. The geometrical (Eqs. (15.115.5 ), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of germanium compounds are given in Tables 23.61, 23.62, and 23.63, respectively. The total energy of each germanium compounds given in Table 22.64 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 23.63 corresponding to functionalgroup composition of the compound. The bond angle parameters of germanium compounds determined using Eqs. (15.8815.117) are given in Table 23.65. The charge-densities of exemplary germanium and digermanium compounds, tetraethylgermanium $\left(\mathrm{Ge}\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right)_{4}\right)$ and hexaethyldigermanium $\left(\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{3} \mathrm{GeGe}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{3}\right)$ comprising atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 23.13A and B, respectively.

Figure 23.13. (A) Color scale, charge-density of $\mathrm{Ge}\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right)_{4}$ showing the orbitals of the Ge and C atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei. (B) Color scale, charge-density of $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{3} \mathrm{GeGe}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{3}$ showing the orbitals of the $G e$ and $C$ atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei.

## TIN FUNCTIONAL GROUPS AND MOLECULES

As in the cases of carbon, silicon and germanium, the bonding in the tin atom involves four $s p^{3}$ hybridized orbitals formed from the $5 p$ and $5 s$ electrons of the outer shells. $S n-X \quad X=$ halide, oxide, $S n-H$, and $S n-S n$ bonds form between $S n 5 s p^{3}$ HOs and between a halide or oxide AO, a $H 1 s \mathrm{AO}$, and a $S n 5 s p^{3} \mathrm{HO}$, respectively to yield tin halides and oxides, stannanes, and distannanes, respectively. The geometrical parameters of each $S n-X \quad X=$ halide, oxide, $S n-H$, and $S n-S n$ functional group is solved from the force balance equation of the electrons of the corresponding $\sigma-\mathrm{MO}$ and the relationships between the prolate spheroidal axes. Then, the sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $\operatorname{Sn} 5 s p^{3}$ shell as in the case of the corresponding carbon and tin molecules. As in the case of the transition metals, the energy of each functional group is determined for the effect of the electron density donation from each participating $S n 5 s p^{3} \mathrm{HO}$ and AO to the corresponding MO that maximizes the bond energy.

The branched-chain alkyl stannanes and distannanes, $S n_{m} C_{n} H_{2(m+n)+2}$, comprise at least a terminal methyl group $\left(\mathrm{CH}_{3}\right)$ and at least one Sn bound by a carbon-tin single bond comprising a $\mathrm{C}-\mathrm{Sn}$ group, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, methylyne $(\mathrm{CH}), \mathrm{C}-\mathrm{C}, \operatorname{SnH} \mathrm{n}_{n=1,2,3}$, and $\mathrm{Sn}-\mathrm{Sn}$ functional groups. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups.

The $S n$ electron configuration is $[K r] 5 s^{2} 4 d^{10} 5 p^{2}$, and the orbital arrangement is:

$$
\begin{gather*}
\begin{array}{c}
5 \mathrm{p} \text { state } \\
\uparrow \\
\frac{\uparrow}{1} \\
\frac{\uparrow}{0} \\
-1
\end{array}-\frac{}{-1}
\end{gather*}
$$

corresponding to the ground state ${ }^{3} P_{0}$. The energy of the carbon $5 p$ shell is the negative of the ionization energy of the tin atom [1] given by:

$$
\begin{equation*}
E(\text { Sn, } 5 p \text { shell })=-E(\text { ionization } ; S n)=-7.34392 \mathrm{eV} \tag{23.217}
\end{equation*}
$$

The energy of tin is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264), but the atomic orbital may hybridize in order to achieve a bond at an energy minimum. After Eq. (13.422), the Sn5s atomic orbital (AO) combines with the $\operatorname{Sn} 5$ p AOs to form a single $\operatorname{Sn} 5 s p^{3}$ hybridized orbital (HO) with the orbital arrangement is:

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the four electrons. The sum $E_{T}\left(S n, 4 s p^{3}\right)$ of experimental energies [1] of $\mathrm{Sn}, \mathrm{Sn}^{+}, \mathrm{Sn}^{2+}$, and $\mathrm{Sn}^{3+}$ is:

$$
\begin{equation*}
E_{T}\left(S n, 5 s p^{3}\right)=40.73502 \mathrm{eV}+30.50260 \mathrm{eV}+14.6322 \mathrm{eV}+7.34392 \mathrm{eV}=93.21374 \mathrm{eV} \tag{23.219}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{5 s p^{3}}$ of the $\operatorname{Sn} 5 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{5 s p^{3}}=\sum_{n=46}^{49} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 93.21374 \mathrm{eV})}=\frac{10 e^{2}}{8 \pi \varepsilon_{0}(e 93.21374 \mathrm{eV})}=1.45964 a_{0} \tag{23.220}
\end{equation*}
$$

where $Z=50$ for tin. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(S n, 5 s p^{3}\right)$ of the outer electron of the $S n 5 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(S n, 5 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{5 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.45964 a_{0}}=-9.321374 \mathrm{eV} \tag{23.221}
\end{equation*}
$$

During hybridization, the spin-paired $5 s$ electrons are promoted to the $\operatorname{Sn} 5 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (15.15) at the initial radius of the $5 s$ electrons. From Eq. (10.255) with $Z=50$, the radius $r_{48}$ of the $\operatorname{Sn5s}$ shell is:

$$
\begin{equation*}
r_{48}=1.33816 a_{0} \tag{23.222}
\end{equation*}
$$

Using Eqs. (15.15) and (23.206), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{48}\right)^{3}}=\frac{8 \pi \mu_{o} \mu_{B}^{2}}{\left(1.33816 a_{0}\right)^{3}}=0.04775 \mathrm{eV} \tag{23.223}
\end{equation*}
$$

Using Eqs. (23.203) and (23.207), the energy $E\left(S n, 5 s p^{3}\right)$ of the outer electron of the $S n 5 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(S n, 5 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{5 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{48}\right)^{3}}=-9.321374 \mathrm{eV}+0.04775 \mathrm{eV}=-9.27363 \mathrm{eV} \tag{23.224}
\end{equation*}
$$

Next, consider the formation of the $S n-L$-bond MO of tin compounds wherein $L$ is a ligand including tin and each tin atom has a $S n 5 s p^{3}$ electron with an energy given by Eq. (23.224). The total energy of the state of each tin atom is given by the sum over the four electrons. The sum $E_{T}\left(S n_{S n-L}, 5 s p^{3}\right)$ of energies of $S n 5 s p^{3}$ (Eq. (23.224)), $\mathrm{Sn}^{+}, \mathrm{Sn}^{2+}$, and $\mathrm{Sn}^{3+}$ is:

$$
\begin{align*}
E_{T}\left(S n_{S n-L}, 5 s p^{3}\right) & =-\left(40.73502 \mathrm{eV}+30.50260 \mathrm{eV}+14.6322 \mathrm{eV}+E\left(S n, 5 s p^{3}\right)\right)  \tag{23.225}\\
& =-(40.73502 \mathrm{eV}+30.50260 \mathrm{eV}+14.6322 \mathrm{eV}+9.27363 \mathrm{eV})=-95.14345 \mathrm{eV}
\end{align*}
$$

where $E\left(S n, 5 s p^{3}\right)$ is the sum of the energy of $S n,-7.34392 \mathrm{eV}$, and the hybridization energy.
A minimum energy is achieved while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical $\left(O H\right.$ ) section with the donation of electron density from the participating $S n 5 s p^{3}$ HO to each $S n-L$-bond MO. As in the case of acetylene given in the Acetylene Molecule section, the energy of each $S n-L$ functional group is determined for the effect of the charge donation. For example, as in the case of the $\mathrm{Si}-\mathrm{Si}$-bond MO given in the Alkyl Silanes and Disilanes section, the sharing of electrons between two $S n 5 s p^{3}$ HOs to form a $S n-S n$-bond MO permits each participating orbital to decrease in size and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each $S n 5 s p^{3}$ HO donates an excess of $25 \%$ of its electron density to the $S n-S n$-bond MO to form an energy minimum. By considering this electron redistribution in the distannane molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, in general terms, the radius $r_{S n-L 5 s p^{3}}$ of the $S n 5 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$
\begin{equation*}
r_{S n-L S s p^{3}}=\left(\sum_{n=46}^{49}(Z-n)-0.25\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 95.14345 \mathrm{eV})}=\frac{9.75 e^{2}}{8 \pi \varepsilon_{0}(e 95.14345 \mathrm{eV})}=1.39428 a_{0} \tag{23.226}
\end{equation*}
$$

Using Eqs. (15.19) and (23.210), the Coulombic energy $E_{\text {Coulomb }}\left(S n_{S n-L}, 5 s p^{3}\right)$ of the outer electron of the $\operatorname{Sn5sp}{ }^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(S n_{S n-L}, 5 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{S n-L S s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.39428 a_{0}}=-9.75830 \mathrm{eV} \tag{23.227}
\end{equation*}
$$

During hybridization, the spin-paired $5 s$ electrons are promoted to the $\operatorname{Sn} 5 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (23.223). Using Eqs. (23.223) and (23.227), the energy $E\left(S n_{S n-L}, 5 s p^{3}\right)$ of the outer electron of the $\operatorname{Sn} 5 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(S n_{S n-L}, 5 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{S n-L S s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{48}\right)^{3}}=-9.75830 \mathrm{eV}+0.04775 \mathrm{eV}=-9.71056 \mathrm{eV} \tag{23.228}
\end{equation*}
$$

Thus, $E_{T}\left(S n-L, 5 s p^{3}\right)$, the energy change of each $S n 5 s p^{3}$ shell with the formation of the $S n-L$-bond MO is given by the difference between Eq. (23.228) and Eq. (23.224).

$$
\begin{equation*}
E_{T}\left(S n-L, 5 s p^{3}\right)=E\left(S n_{S n-L}, 5 s p^{3}\right)-E\left(S n, 5 s p^{3}\right)=-0.43693 \mathrm{eV} \tag{23.229}
\end{equation*}
$$

Next, consider the formation of the $S n-L$-bond MO of additional functional groups wherein each tin atom contributes a $S n 5 s p^{3}$ electron having the sum $E_{T}\left(S n_{S n-L}, 5 s p^{3}\right)$ of energies of $S n 5 s p^{3}$ (Eq. (23.224)), $S n^{+}, S n^{2+}$, and $S n^{3+}$ given by Eq. (23.209). Each $S n-L$-bond MO of each functional group $S n-L$ forms with the sharing of electrons between a $S n 5 s p^{3}$ HO and a AO or HO of $L$, and the donation of electron density from the $S n 5 s p^{3} \mathrm{HO}$ to the $S n-L$-bond MO permits the participating orbitals to decrease in size and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships while forming an energy minimum, the permitted values of the excess fractional charge of its electron density that the $S n 5 s p^{3}$ HO donates to the $S n-L$-bond MO given by Eq. (15.18) is $s(0.25) ; \quad s=1,2,3,4$ and linear combinations thereof. By considering this electron redistribution in the tin molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{S n-L S s p^{3}}$ of the $S n 5 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$
\begin{equation*}
r_{S n-L 5 s p^{3}}=\left(\sum_{n=46}^{49}(Z-n)-s(0.25)\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 95.14345 \mathrm{eV})}=\frac{(10-s(0.25)) e^{2}}{8 \pi \varepsilon_{0}(e 95.14345 \mathrm{eV})} \tag{23.230}
\end{equation*}
$$

Using Eqs. (15.19) and (23.230), the Coulombic energy $E_{\text {Coulomb }}\left(S n_{S n-L}, 5 s p^{3}\right)$ of the outer electron of the $S n 5 s p^{3}$ shell is

$$
\begin{equation*}
E_{\text {Coulomb }}\left(S n_{S n-L}, 5 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{S n-L 5 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} \frac{(10-s(0.25)) e^{2}}{8 \pi \varepsilon_{0}(e 95.14345 \mathrm{eV})}}=\frac{95.14345 \mathrm{eV}}{(10-s(0.25))} \tag{23.231}
\end{equation*}
$$

During hybridization, the spin-paired $5 s$ electrons are promoted to the $\operatorname{Sn} 5 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (23.223). Using Eqs. (23.223) and (23.231), the energy $E\left(S n_{S n-L}, 5 s p^{3}\right)$ of the outer electron of the $\operatorname{Sn} 5 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(S n_{S n-L}, 5 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{S n-L S s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{48}\right)^{3}}=\frac{95.14345 \mathrm{eV}}{(10-s(0.25))}+0.04775 \mathrm{eV} \tag{23.232}
\end{equation*}
$$

Thus, $E_{T}\left(S n-L, 5 s p^{3}\right)$, the energy change of each $S n 5 s p^{3}$ shell with the formation of the $S n-L$-bond MO is given by the difference between Eq. (23.232) and Eq. (23.224).

$$
\begin{equation*}
E_{T}\left(S n-L, 5 s p^{3}\right)=E\left(S n_{S n-L}, 5 s p^{3}\right)-E\left(S n, 5 s p^{3}\right)=-\frac{95.14345}{(10-s(0.25))} \mathrm{eV}+0.04775 \mathrm{eV}-(-9.27363 \mathrm{eV}) \tag{23.233}
\end{equation*}
$$

Using Eq. (15.28) for the case that the energy matching and energy minimum conditions of the MOs in the tin molecule are met by a linear combination of values of $s\left(s_{1}\right.$ and $\left.s_{2}\right)$ in Eqs. (23.230-23.233), the energy $E\left(S n_{S n-L}, 5 s p^{3}\right)$ of the outer electron of the $\operatorname{Sn} 5 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(S n_{S n-L}, 5 s p^{3}\right)=\frac{\frac{95.14345 \mathrm{eV}}{\left(10-s_{1}(0.25)\right)}+\frac{95.14345 \mathrm{eV}}{\left(10-s_{2}(0.25)\right)}+2(0.04775 \mathrm{eV})}{2} \tag{23.234}
\end{equation*}
$$

Using Eqs. (15.13) and (23.234), the radius corresponding to Eq. (23.234) is:

$$
\begin{equation*}
r_{5 s p^{3}}=\frac{e^{2}}{8 \pi \varepsilon_{0} E\left(S n_{S n-L}, 5 s p^{3}\right)}=\frac{e^{2}}{8 \pi \varepsilon_{0}\left(e\left(\frac{\frac{95.14345 \mathrm{eV}}{\left(10-s_{1}(0.25)\right)}+\frac{95.14345 \mathrm{eV}}{\left(10-s_{2}(0.25)\right)}+2(0.04775 \mathrm{eV})}{2}\right)\right)} \tag{23.235}
\end{equation*}
$$

$E_{T}\left(S n-L, 5 s p^{3}\right)$, the energy change of each $S n 5 s p^{3}$ shell with the formation of the $S n-L$-bond MO is given by the difference between Eq. (23.235) and Eq. (23.224).

$$
\begin{align*}
E_{T}\left(S n-L, 5 s p^{3}\right)= & E\left(S n_{S n-L}, 5 s p^{3}\right)-E\left(S n, 5 s p^{3}\right) \\
& =\frac{\frac{95.14345 \mathrm{eV}}{\left(10-s_{1}(0.25)\right)}+\frac{95.14345 \mathrm{eV}}{\left(10-s_{2}(0.25)\right)}+2(0.04775 \mathrm{eV})}{2}-(-9.27363 \mathrm{eV}) \tag{23.236}
\end{align*}
$$

$E_{T}\left(S n-L, 5 s p^{3}\right)$ is also given by Eq. (15.29). Bonding parameters for the $S n-L$-bond MO of tin functional groups due to charge donation from the HO to the MO are given in Table 23.66.

Table 23.66. The values of $r_{S n s s p^{3}}, E_{\text {Coulomb }}\left(S n_{S n-L}, 5 s p^{3}\right)$, and $E\left(S n_{S n-L}, 5 s p^{3}\right)$ and the resulting $E_{T}\left(S n-L, 5 s p^{3}\right)$ of the MO due to charge donation from the HO to the MO .

The semimajor axis $a$ solution given by Eq. (23.41) of the force balance equation, Eq. (23.39), for the $\sigma$-MO of the $S n-L$-bond MO of $S n L_{n}$ is given in Table 23.68 with the force-equation parameters $Z=50, n_{e}$, and $L$ corresponding to the orbital and spin angular momentum terms of the $4 s$ HO shell. The semimajor axis $a$ of organometallic compounds, stannanes and distannanes, are solved using Eq. (15.51).

For the $S n-L$ functional groups, hybridization of the $5 p$ and $5 s$ AOs of $S n$ to form a single $S n 5 s p^{3}$ HO shell forms an energy minimum, and the sharing of electrons between the $\operatorname{Sn} 5 s p^{3} \mathrm{HO}$ and $L$ AO to form a MO permits each participating orbital to decrease in radius and energy. The Cl AO has an energy of $E(\mathrm{Cl})=-12.96764 \mathrm{eV}$, the Br AO has an energy of $E(B r)=-11.8138 \mathrm{eV}$, the $I$ AO has an energy of $E(I)=-10.45126 \mathrm{eV}$, the $O$ AO has an energy of $E(O)=-13.61805 \mathrm{eV}$, the $C 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), 13.605804 eV is the magnitude of the Coulombic energy between the electron and proton of $H$ (Eq. (1.264)), the Coulomb energy of the $S n 5 s p^{3} H O$ is $E_{\text {Coulomb }}\left(S n, 5 s p^{3} H O\right)=-9.32137 \mathrm{eV}$ (Eq. (23.205)), and the $\operatorname{Sn5sp^{3}} \mathrm{HO}$ has an energy of $E\left(S n, 5 s p^{3} \mathrm{HO}\right)=-9.27363 \mathrm{eV}$ (Eq. (23.208)). To meet the equipotential condition of the union of the $S n-L \quad H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor(s), at least one of $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $S n-L$-bond MO given by Eq. (15.77) is:

$$
\begin{align*}
& c_{2}\left(\text { ClAO to Sn5sp }{ }^{3} \mathrm{HO}\right)=C_{2}\left(\text { ClAO to Sn5sp }{ }^{3} \mathrm{HO}\right)=\frac{E\left(S n, 5 s p^{3}\right)}{E(C l A O)}=\frac{-9.27363 \mathrm{eV}}{-12.96764 \mathrm{eV}}=0.71514  \tag{23.237}\\
& C_{2}\left(\text { BrAO to } S n 5 s p^{3} H O\right)=\frac{E\left(S n, 5 s p^{3}\right)}{E(B r A O)}=\frac{-9.27363 \mathrm{eV}}{-11.8138 \mathrm{eV}}=0.78498  \tag{23.238}\\
& c_{2}\left(\text { IAO to Sn5sp }{ }^{3} \mathrm{HO}\right)=\frac{E\left(\operatorname{Sn}, \operatorname{Sn} 5 s p^{3}\right)}{E(I A O)}=\frac{-9.27363 \mathrm{eV}}{-10.45126 \mathrm{eV}}=0.88732  \tag{23.239}\\
& c_{2}\left(O \text { to Sn } 5 s p^{3} \mathrm{HO}\right)=C_{2}\left(O \text { to } \operatorname{Sn} 5 s p^{3} \mathrm{HO}\right)=\frac{E\left(S n, 5 s p^{3}\right)}{E(O)}=\frac{-9.27363 \mathrm{eV}}{-13.61805 \mathrm{eV}}=0.68098  \tag{23.240}\\
& c_{2}\left(H A O \text { to Sn5sp }{ }^{3} H O\right)=\frac{E_{\text {Coulomb }}\left(S n, 5 s p^{3}\right)}{E(H)}=\frac{-9.32137 \mathrm{eV}}{-13.605804 \mathrm{eV}}=0.68510  \tag{23.241}\\
& C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Sn} 5 s p^{3} \mathrm{HO}\right)=\frac{E\left(S n, 5 s p^{3} \mathrm{HO}\right)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-9.27363 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.58152  \tag{23.242}\\
& c_{2}\left(S n 5 s p^{3} \mathrm{HO} \text { to Sn5sp }{ }^{3} \mathrm{HO}\right)=\frac{E_{\text {Coulomb }}\left(S n, 5 s p^{3}\right)}{E(H)}=\frac{-9.32137 \mathrm{eV}}{-13.605804 \mathrm{eV}}=0.68510 \tag{23.243}
\end{align*}
$$

where Eq. (15.71) was used in Eqs. (23.241) and (23.243) and Eqs. (15.76), (15.79), and (13.430) were used in Eq. (23.242). Since the energy of the MO is matched to that of the $\operatorname{Sn} 5 s p^{3} \mathrm{HO}, E(A O / H O)$ in Eq. (15.61) is $E\left(S n, 5 s p^{3} H O\right)$ given by Eq. (23.224) for single bonds and twice this value for double bonds. $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $S n-L$-bond MO is determined by considering that the bond involves up to an electron transfer from the tin atom to the ligand atom to form partial ionic character in the bond as in the case of the zwitterions such as $\mathrm{H}_{2} \mathrm{~B}^{+}-F^{-}$given in the Halido Boranes section. For the tin compounds, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is that which forms an energy minimum for the hybridization and other bond parameter. The general values of Table 23.66 are given by Eqs. (23.233) and (23.226), and the specific values for the tin functional groups are given in Table 23. 70.

The symbols of the functional groups of tin compounds are given in Table 23.67. The geometrical (Eqs. (15.1-15.5) and (23.41)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of tin compounds are given in Tables 23.68, 23.69, and 23.70, respectively. The total energy of each tin compound given in Table 22.71 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 23.70 corresponding to functional-group composition of the compound. The bond angle parameters of tin compounds determined using Eqs. (15.88-15.117) are given in Table 23.72. The $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ term for $\mathrm{SnCl}_{4}$ was calculated using Eqs. (23.230-23.277) with $s=1$ for the energies of $E\left(S n, 5 s p^{3}\right)$. The charge-densities of exemplary tin coordinate and organometallic compounds, tin tetrachloride $\left(\mathrm{SnCl}_{4}\right)$ and hexaphenyldistannane $\left(\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3} \operatorname{SnSn}\left(\mathrm{C}_{6} H_{5}\right)_{3}\right)$ comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 23.14 and 23.15 , respectively.

Figure 23.14. Tin Tetrachloride. Color scale, translucent view of the charge-density of $\mathrm{SnCl}_{4}$ showing the orbitals of the Sn and Cl atoms at their radii, the ellipsoidal surface of each $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the nuclei (red, not to scale).

Figure 23.15. (A) and (B) Hexaphenyldistannane. Color scale, opaque view of the charge-density of $\left(C_{6} H_{5}\right)_{3} \operatorname{SnSn}\left(\mathrm{C}_{6} H_{5}\right)_{3}$ showing the orbitals of the Sn and C atoms at their radii and the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond.

Table 23.67. The symbols of functional groups of tin compounds.

| Functional Group | Group Symbol |
| :---: | :---: |
| SnCl group | $\mathrm{Sn}-\mathrm{Cl}$ |
| SnBr group | $\mathrm{Sn}-\mathrm{Br}$ |
| SnI group | Sn-I |
| SnO group | $\mathrm{Sn}-\mathrm{O}$ |
| SnH group | $\mathrm{Sn}-\mathrm{H}$ |
| SnC group | Sn-C |
| SnSn group | $\mathrm{Sn}-\mathrm{Sn}$ |
| $\mathrm{CH}_{3}$ group | $\mathrm{C}-\mathrm{H}\left(\mathrm{CH}_{3}\right)$ |
| $\mathrm{CH}_{2}$ alkyl group | $\mathrm{C}-\mathrm{H}\left(\mathrm{CH}_{2}\right)$ (i) |
| CH alkyl | C-H (i) |
| $C C$ bond ( $n-C$ ) | $C-C$ (a) |
| $C C$ bond (iso-C) | $C-C$ (b) |
| $C C$ bond (tert-C) | $C-C$ (c) |
| $C C$ (iso to iso-C) | $C-C$ (d) |
| $C C(t$ to $t-C)$ | $C-C$ (e) |
| $C C$ ( $t$ to iso-C) | $C-C$ (f) |
| $C C$ double bond | $C=C$ |
| $C$ vinyl single bond to $-C(C)=C$ | $C-C$ (i) |
| $C$ vinyl single bond to $-C(H)=C$ | $C-C$ (ii) |
| C vinyl single bond to $-\mathrm{C}(\mathrm{C})=\mathrm{CH}_{2}$ | $C-C$ (iii) |
| $\mathrm{CH}_{2}$ alkenyl group | $\mathrm{C}-\mathrm{H}\left(\mathrm{CH}_{2}\right)$ (ii) |
| $C C$ (aromatic bond) | $C \stackrel{3 e}{=} C$ |
| CH (aromatic) | CH (ii) |
| $\mathrm{C}_{a}-\mathrm{C}_{b}\left(\mathrm{CH}_{3}\right.$ to aromatic bond) | $C-C$ (iv) |
| C-C(O) | $C-C(O)$ |
| $C=O$ (aryl carboxylic acid) | $C=O$ |
| (O) $\mathrm{C}-\mathrm{O}$ | C-O |
| OH group | OH |

## LEAD ORGANOMETALLIC FUNCTIONAL GROUPS AND MOLECULES

The branched-chain alkyl lead molecules, $P b C_{n} H_{2 n-2}$, comprise at least one $P b$ bound by a carbon-lead single bond comprising a $\mathrm{C}-\mathrm{Pb}$ group, at least a terminal methyl group $\left(\mathrm{CH}_{3}\right)$, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, methylyne ( CH ), and $\mathrm{C}-\mathrm{C}$ functional groups. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and tbutyl to t-butyl $C-C$ bonds comprise functional groups.

As in the cases of carbon, silicon, tin, and germanium, the bonding in the lead atom involves four $s p^{3}$ hybridized orbitals. For lead, they are formed from the $6 p$ and $6 s$ electrons of the outer shells. $P b-C$ bonds form between a $P b 6 s p^{3}$ HO and a $C 3 s p^{3} \mathrm{HO}$ to yield alkyl leads. The geometrical parameters of the $\mathrm{Pb}-C$ functional group are solved using Eq. (15.51) and the relationships between the prolate spheroidal axes. Then, the sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $P b 6 s p^{3}$ shell as in the case of the corresponding carbon, silicon, tin, germanium molecules. As in the case of the transition metals, the energy of each functional group is determined for the effect of the electron density donation from each participating $C 3 s p^{3} \mathrm{HO}$ and $P b 6 s p^{3} \mathrm{HO}$ to the corresponding MO that maximizes the bond energy.

The $P b$ electron configuration is $[X e] 6 s^{2} 4 f^{14} 5 d^{10} 6 p^{2}$, and the orbital arrangement is:

$$
\begin{equation*}
6 \mathrm{p} \text { state } \tag{23.244}
\end{equation*}
$$

corresponding to the ground state ${ }^{3} P_{0}$. The energy of the lead $6 p$ shell is the negative of the ionization energy of the lead atom [1] given by:

$$
\begin{equation*}
E(P b, 6 p \text { shell })=-E(\text { ionization } ; P b)=-7.41663 \mathrm{eV} \tag{23.245}
\end{equation*}
$$

The energy of lead is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264), but the atomic orbital may hybridize in order to achieve a bond at an energy minimum. After Eq. (13.422), the Pb6s atomic orbital (AO) combines with the $P b 6 p$ AOs to form a single $P b 6 s p^{3}$ hybridized orbital (HO) with the orbital arrangement

\[

\]

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the four electrons. The sum $E_{T}\left(\mathrm{~Pb}, 6 s p^{3}\right)$ of experimental energies [1] of $\mathrm{Pb}, \mathrm{Pb}^{+}, \mathrm{Pb}^{2+}$, and $\mathrm{Pb}^{3+}$ is:

$$
\begin{equation*}
E_{T}\left(P b, 6 s p^{3}\right)=42.32 \mathrm{eV}+31.9373 \mathrm{eV}+15.03248 \mathrm{eV}+7.41663 \mathrm{eV}=96.70641 \mathrm{eV} \tag{23.247}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{6 s p^{3}}$ of the $P b 6 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{6 s p^{3}}=\sum_{n=78}^{81} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 96.70641 \mathrm{eV})}=\frac{10 e^{2}}{8 \pi \varepsilon_{0}(e 96.70641 \mathrm{eV})}=1.40692 a_{0} \tag{23.248}
\end{equation*}
$$

where $Z=82$ for lead. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(P b, 6 s p^{3}\right)$ of the outer electron of the $P b 6 s p^{3}$ shell is

$$
\begin{equation*}
E_{\text {Coulomb }}\left(P b, 6 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{6 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.40692 a_{0}}=-9.67064 \mathrm{eV} \tag{23.249}
\end{equation*}
$$

During hybridization, the spin-paired $6 s$ electrons are promoted to the $P b 6 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (15.15) at the initial radius of the $6 s$ electrons. From Eq. (10.102) with $Z=82$ and $n=80$, the radius $r_{80}$ of the Pb6s shell is:

$$
\begin{equation*}
r_{80}=1.27805 a_{0} \tag{23.250}
\end{equation*}
$$

Using Eqs. (15.15) and (23.250), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{80}\right)^{3}}=\frac{8 \pi \mu_{o} \mu_{B}^{2}}{\left(1.27805 a_{0}\right)^{3}}=0.05481 \mathrm{eV} \tag{23.251}
\end{equation*}
$$

Using Eqs. (23.249) and (23.251), the energy $E\left(P b, 6 s p^{3}\right)$ of the outer electron of the $P b 6 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(P b, 6 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{6 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{80}\right)^{3}}=-9.67064 \mathrm{eV}+0.05481 \mathrm{eV}=-9.61584 \mathrm{eV} \tag{23.252}
\end{equation*}
$$

Next, consider the formation of the $\mathrm{Pb}-L$-bond MO of lead compounds wherein $L$ is a ligand including carbon and each lead atom has a $P b 6 s p^{3}$ electron with an energy given by Eq. (23.252). The total energy of the state of each lead atom is given by the sum over the four electrons. The sum $E_{T}\left(P b_{P b-L}, 6 s p^{3}\right)$ of energies of $P b 6 s p^{3}$ (Eq. (23.252)), $P b^{+}, P b^{2+}$, and $P b^{3+}$ is:

$$
\begin{align*}
E_{T}\left(P b_{P b-L}, 6 s p^{3}\right) & =-\left(42.32 \mathrm{eV}+31.9373 \mathrm{eV}+15.03248 \mathrm{eV}+E\left(P b, 6 s p^{3}\right)\right)  \tag{23.253}\\
& =-(42.32 \mathrm{eV}+31.9373 \mathrm{eV}+15.03248 \mathrm{eV}+9.61584 \mathrm{eV})=-98.90562 \mathrm{eV}
\end{align*}
$$

where $E\left(P b, 6 s p^{3}\right)$ is the sum of the energy of $P b,-7.41663 \mathrm{eV}$, and the hybridization energy.
A minimum energy is achieved while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical $\left(O H\right.$ ) section with the donation of electron density from the participating $P b 6 s p^{3} \mathrm{HO}$ to each $\mathrm{Pb}-L$-bond MO. Consider the case wherein each Pb6sp ${ }^{3}$ HO donates an excess of $25 \%$ of its electron density to the $P b-L$-bond MO to form an energy minimum. By considering this electron redistribution in the lead molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, in general terms, the radius $r_{P b-L 6 s p^{3}}$ of the $P b 6 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$
\begin{equation*}
r_{P b-L 6 s p^{3}}=\left(\sum_{n=78}^{81}(Z-n)-0.25\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 98.90562 \mathrm{eV})}=\frac{9.75 e^{2}}{8 \pi \varepsilon_{0}(e 98.90562 \mathrm{eV})}=1.34124 a_{0} \tag{23.254}
\end{equation*}
$$

Using Eqs. (15.19) and (23.254), the Coulombic energy $E_{\text {Coulomb }}\left(P b_{P b-L}, 6 s p^{3}\right)$ of the outer electron of the $P b 6 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(P b_{P b-L}, 6 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{P b-L 6 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.34124 a_{0}}=-10.14417 \mathrm{eV} \tag{23.255}
\end{equation*}
$$

During hybridization, the spin-paired $6 s$ electrons are promoted to the $P b 6 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (23.251). Using Eqs. (23.251) and (23.255), the energy $E\left(P b_{P b-L}, 6 s p^{3}\right)$ of the outer electron of the $P b 6 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(P b_{P b-L}, 6 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{P b-L 6 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{80}\right)^{3}}=-10.14417 \mathrm{eV}+0.05481 \mathrm{eV}=-10.08936 \mathrm{eV} \tag{23.256}
\end{equation*}
$$

Thus, $E_{T}\left(P b-L, 6 s p^{3}\right)$, the energy change of each $P b 6 s p^{3}$ shell with the formation of the $P b-L$-bond MO is given by the difference between Eq. (23.256) and Eq. (23.252).

$$
\begin{equation*}
E_{T}\left(P b-L, 6 s p^{3}\right)=E\left(P b_{P b-L}, 6 s p^{3}\right)-E\left(P b, 6 s p^{3}\right)=-10.08936 \mathrm{eV}-(-9.61584 \mathrm{eV})=-0.47352 \mathrm{eV} \tag{23.257}
\end{equation*}
$$

Next, consider the formation of the $\mathrm{Pb}-C$-bond MO by bonding with a carbon having a $C 2 s p^{3}$ electron with an energy given by Eq. (14.146). The total energy of the state is given by the sum over the four electrons. The sum $E_{T}\left(C_{\text {ethane }}, 2 s p^{3}\right)$ of calculated energies of $C 2 s p^{3}, C^{+}, C^{2+}$, and $C^{3+}$ from Eqs. (10.123), (10.113-10.114), (10.68), and (10.48), respectively, is:

$$
\begin{align*}
E_{T}\left(C_{\text {ethane }}, 2 s p^{3}\right) & =-\left(64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+E\left(C, 2 s p^{3}\right)\right)  \tag{23.258}\\
& =-(64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+14.63489 \mathrm{eV})=-151.61569 \mathrm{eV}
\end{align*}
$$

where $E\left(C, 2 s p^{3}\right)$ is the sum of the energy of $C,-11.27671 \mathrm{eV}$, and the hybridization energy.
The sharing of electrons between the $P b 6 s p^{3} \mathrm{HO}$ and $C 2 s p^{3} \mathrm{HOs}$ to form a $\mathrm{Pb}-\mathrm{C}$-bond MO permits each participating hybridized orbital to decrease in radius and energy. A minimum energy is achieved while satisfying the potential, kinetic, and orbital energy relationships, when the $P b 6 s p^{3} \mathrm{HO}$ donates, and the $C 2 s p^{3} \mathrm{HO}$ receives, excess electron density equivalent to an electron within the $\mathrm{Pb}-\mathrm{C}$-bond MO. By considering this electron redistribution in the alkyl lead molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{P b-C 2 s p^{3}}$ of the $C 2 s p^{3}$ shell of the $\mathrm{Pb}-\mathrm{C}$-bond MO may be calculated from the Coulombic energy using Eqs. (15.18) and (23.258).

$$
\begin{equation*}
r_{P b-C 2 s p^{3}}=\left(\sum_{n=2}^{5}(Z-n)+1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 151.61569 \mathrm{eV})}=\frac{11 e^{2}}{8 \pi \varepsilon_{0}(e 151.61569 \mathrm{eV})}=0.98713 a_{0} \tag{23.259}
\end{equation*}
$$

Using Eqs. (15.19) and (23.259), the Coulombic energy $E_{\text {Coulomb }}\left(C_{P b-C}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is

$$
\begin{equation*}
E_{\text {Coulomb }}\left(C_{P b-C}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{P b-C 2 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.98713 a_{0}}=-13.78324 \mathrm{eV} \tag{23.260}
\end{equation*}
$$

During hybridization, the spin-paired $2 s$ electrons are promoted to the $C 2 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (14.145). Using Eqs. (14.145) and (23.260), the energy $E\left(C_{P b-C}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(C_{P b-C}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{P b-C 2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-13.78324 \mathrm{eV}+0.19086 \mathrm{eV}=-13.59238 \mathrm{eV} \tag{23.261}
\end{equation*}
$$

Thus, $E_{T}\left(P b-C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell with the formation of the $P b-C$-bond MO is given by the difference between Eq. (23.261) and Eq. (14.146).

$$
\begin{equation*}
E_{T}\left(P b-C, 2 s p^{3}\right)=E\left(C_{P b-C}, 2 s p^{3}\right)-E\left(C, 2 s p^{3}\right)=-13.59238 \mathrm{eV}-(-14.63489 \mathrm{eV})=1.04251 \mathrm{eV} \tag{23.262}
\end{equation*}
$$

Now, consider the formation of the $P b-L$-bond MO of lead compounds wherein $L$ is a ligand including carbon. For the $P b-L$ functional groups, hybridization of the $6 p$ and $6 s$ AOs of $P b$ to form a single $P b 6 s p^{3}$ HO shell forms an energy minimum, and the sharing of electrons between the $P b 6 s p^{3} \mathrm{HO}$ and $L \mathrm{HO}$ to form a MO permits each participating orbital to decrease in radius and energy. The $C 2 s p^{3}$ HO has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)) and the Pb6sp HO has an energy of $E\left(P b, 6 s p^{3}\right)=-9.61584 \mathrm{eV}$ (Eq. (23.252)). To meet the equipotential condition of the union of the $P b-L$ $H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factors $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $P b-L$-bond MO given by Eq. (15.77) are:

Since the energy of the MO is matched to that of the $\operatorname{Pb6sp^{3}} \mathrm{HO}, E(A O / H O)$ in Eq. (15.61) is $E\left(P b, 6 s p^{3} H O\right)$ given by Eq. (23.252). In order to match the energies of the carbon and lead HOs within the molecule, $E_{T}\left(\right.$ atom -atom, $m s p^{3} . A O$ ) of the $\mathrm{Pb}-L$-bond MO for the ligand carbon is one half $E_{T}\left(P b-C, 2 s p^{3}\right)$ (Eq. (23.262)).

The symbols of the functional groups of lead compounds are given in Table 23.73. The geometrical (Eqs. (15.1-15.5)), intercept (Eqs. (15.31-15.32) and (15.80-15.87)), and energy (Eqs. (15.61) and (23.28-23.33)) parameters of lead compounds are given in Tables $23.74,23.75$, and 23.76 , respectively. The total energy of each lead compound given in Table 22.77 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 23.76 corresponding to functional-group composition of the compound. The bond angle parameters of lead compounds determined using Eqs. (15.88-15.117) are given in Table 23.78. The charge-densities of exemplary lead compound, tetraethyl lead $\left(\mathrm{Pb}\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right)_{4}\right)$ comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figure 23.16.

Figure 23.16. Color scale, charge-density of $\mathrm{Pb}\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right)_{4}$ showing the orbitals of the Pb and C atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond, and the hydrogen nuclei.

Table 23.73. The symbols of functional groups of lead compounds.

| Functional Group | Group Symbol |

Table 23.77. The total bond energies of gaseous-state lead compounds calculated using the functional group composition (separate functional groups designated in the first row) and the energies of Table 23.76 compared to the gaseous-state experimental values [86].

Table 23.78. The bond angle parameters of lead compounds and experimental values [3]. In the calculation of $\theta_{v}$, the parameters from the preceding angle were

## ALKYL ARSINES $\left(\left(C_{n} H_{2 n+1}\right)_{3} A s, n=1,2,3,4,5 \ldots \infty\right)$

The alkyl arsines, $\left(C_{n} H_{2 n+1}\right)_{3} A s$, comprise a $A s-C$ functional group. The alkyl portion of the alkyl arsine may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of each chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl arsines are equivalent to those in branched-chain alkanes. The $A s-C$ group may further join the $A s 4 s p^{3} \mathrm{HO}$ to an aryl HO.

As in the case of phosphorous, the bonding in the arsenic atom involves $s p^{3}$ hybridized orbitals formed, in this case, from the $4 p$ and $4 s$ electrons of the outer shells. The $A s-C$ bond forms between $A s 4 s p^{3}$ and $C 2 s p^{3}$ HOs to yield arsines. The semimajor axis $a$ of the $A s-C$ functional group is solved using Eq. (15.51). Using the semimajor axis and the relationships between the prolate spheroidal axes, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in the Organic Molecular Functional Groups and Molecules section.

The energy of arsenic is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). A minimum energy is achieved while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical ( $O H$ ) section with hybridization of the arsenic atom such that in Eqs. (15.51) and (15.61), the sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $A s 4 s p^{3}$ shell as in the case of the corresponding phosphine molecules.

The $A s$ electron configuration is $[A r] 4 s^{2} 3 d^{10} 4 p^{3}$ corresponding to the ground state ${ }^{4} S_{3 / 2}$, and the $4 s p^{3}$ hybridized orbital arrangement after Eq. (13.422) is:

$$
\frac{\uparrow}{1,1}
$$

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the five electrons. The sum $E_{T}\left(A s, 4 s p^{3}\right)$ of experimental energies [1] of $A s, A s^{+}, A s^{2+}, A s^{3+}$, and $A s^{4+}$ is:

$$
\begin{equation*}
E_{T}\left(A s, 4 s p^{3}\right)=62.63 \mathrm{eV}+50.13 \mathrm{eV}+28.351 \mathrm{eV}+18.5892 \mathrm{eV}+9.7886 \mathrm{eV}=169.48880 \mathrm{eV} \tag{23.265}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{4 s p^{3}}$ of the $A s 4 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{4 s p^{3}}=\sum_{n=28}^{32} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 169.48880 \mathrm{eV})}=\frac{15 e^{2}}{8 \pi \varepsilon_{0}(e 169.48880 \mathrm{eV})}=1.20413 a_{0} \tag{23.266}
\end{equation*}
$$

where $Z=33$ for arsenic. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(A s, 4 s p^{3}\right)$ of the outer electron of the $A s 4 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(A s, 4 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{4 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.20413 a_{0}}=-11.29925 \mathrm{eV} \tag{23.267}
\end{equation*}
$$

During hybridization, the spin-paired $4 s$ electrons are promoted to the $A s 4 s p^{3}$ shell as paired electrons at the radius $r_{4 s p^{3}}$ of the $A s 4 s p^{3}$ shell. The energy for the promotion is the difference in the magnetic energy given by Eq. (15.15) at the initial radius of the $4 s$ electrons and the final radius of the $A s 4 s p^{3}$ electrons. From Eq. (10.102) with $Z=33$ and $n=30$, the radius $r_{30}$ of the As $4 s$ shell is:

$$
\begin{equation*}
r_{30}=1.08564 a_{0} \tag{23.268}
\end{equation*}
$$

Using Eqs. (15.15) and (23.268), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}}\left(\frac{1}{\left(r_{30}\right)^{3}}-\frac{1}{\left(r_{4 s p^{3}}\right)^{3}}\right)=8 \pi \mu_{o} \mu_{B}^{2}\left(\frac{1}{\left(1.08564 a_{0}\right)^{3}}-\frac{1}{\left(1.20413 a_{0}\right)^{3}}\right)=0.02388 \mathrm{eV} \tag{23.269}
\end{equation*}
$$

Using Eqs. (23.267) and (23.269), the energy $E\left(A s, 4 s p^{3}\right)$ of the outer electron of the $A s 4 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(A s, 4 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{4 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}}\left(\frac{1}{\left(r_{30}\right)^{3}}-\frac{1}{\left(r_{4 s p^{3}}\right)^{3}}\right)=-11.29925 \mathrm{eV}+0.02388 \mathrm{eV}=-11.27537 \mathrm{eV} \tag{23.270}
\end{equation*}
$$

For the $A s-C$ functional group, hybridization of the $2 s$ and $2 p$ AOs of each $C$ and the $4 s$ and $4 p$ AOs of each $A s$ to form single $2 s p^{3}$ and $4 s p^{3}$ shells, respectively, forms an energy minimum, and the sharing of electrons between the $C 2 s p^{3}$ and $A s 4 s p^{3}$ HOs to form a MO permits each participating orbital to decrease in radius and energy. In branched-chain alkyl arsines, the energy of arsenic is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{2}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $C_{2}$ parameter. Then, the $C 2 s p^{3} \mathrm{HO}$ has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $A s 4 s p^{3} \mathrm{HO}$ has an energy of $E\left(A s, 4 s p^{3}\right)=-11.27537 \mathrm{eV}$ (Eq. (23.270)). To meet the equipotential condition of the union of the $A s-C H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $C_{2}$ of Eq. (15.61) for the $A s-C$-bond MO given by Eqs. (15.77), (15.79), and (13.430) is:

$$
\begin{equation*}
C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{As} 4 s p^{3} \mathrm{HO}\right)=\frac{E\left(A s, 4 s p^{3}\right)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-11.27537 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.70705 \tag{23.271}
\end{equation*}
$$

The energy of the $A s-C$-bond MO is the sum of the component energies of the $H_{2}$-type ellipsoidal MO given in Eq. (15.51) with $E(A O / H O)=E\left(A s, 4 s p^{3}\right)$ given by Eq. (23.270), and $E_{T}\left(\right.$ atom -atom, $\left.m s p^{3} . A O\right)$ is zero in order to match the energies of the carbon and arsenic HOs.

The symbols of the functional groups of branched-chain alkyl arsines are given in Table 23.79. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl arsines are given in Tables 23.80, 23.81, and 23.82, respectively. The total energy of each alkyl arsine given in Table 23.83 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 23.82 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl arsines determined using Eqs. (15.88-15.117) are given in Table 23.84. The color scale, charge-density of exemplary alkyl arsine, triphenylarsine, comprising atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 23.17.

Figure 23.17. Color scale, charge-density of triphenylarsine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei.

## ALKYL STIBINES $\left(\left(C_{n} H_{2 n+1}\right)_{3} S b, n=1,2,3,4,5 \ldots \infty\right)$

The alkyl stibines, $\left(\mathrm{C}_{n} \mathrm{H}_{2 n+1}\right)_{3} \mathrm{Sb}$, comprise a $\mathrm{Sb}-\mathrm{C}$ functional group. The alkyl portion of the alkyl stibine may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of each chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl stibines are equivalent to those in branched-chain alkanes. The $S b-C$ group may further join the $S b 5 s p^{3}$ HO to an aryl HO.

As in the case of phosphorous, the bonding in the antimony atom involves $s p^{3}$ hybridized orbitals formed, in this case, from the $5 p$ and $5 s$ electrons of the outer shells. The $S b-C$ bond forms between $S b 5 s p^{3}$ and $C 2 s p^{3}$ HOs to yield stibines. The semimajor axis $a$ of the $S b-C$ functional group is solved using Eq. (15.51). Using the semimajor axis and the relationships between the prolate spheroidal axes, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in the Organic Molecular Functional Groups and Molecules section.

The energy of antimony is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). A minimum energy is achieved while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical ( $O H$ ) section with hybridization of the antimony atom such that in Eqs. (15.51) and (15.61), the sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $S b 5 s p^{3}$ shell as in the case of the corresponding phosphine and arsine molecules.

The $S b$ electron configuration is $[K r] 5 s^{2} 4 d^{10} 5 p^{3}$ corresponding to the ground state ${ }^{4} S_{3 / 2}$, and the $5 s p^{3}$ hybridized orbital arrangement after Eq. (13.422) is:

\[

\]

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the five electrons. The sum $E_{T}\left(S b, 5 s p^{3}\right)$ of experimental energies [1] of $S b, S b^{+}, S b^{2+}, S b^{3+}$, and $S b^{4+}$ is:

$$
\begin{equation*}
E_{T}\left(S b, 5 s p^{3}\right)=56.0 \mathrm{eV}+44.2 \mathrm{eV}+25.3 \mathrm{eV}+16.63 \mathrm{eV}+8.60839 \mathrm{eV}=150.73839 \mathrm{eV} \tag{23.273}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{5 s p^{3}}$ of the $S b 5 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{5 s p^{3}}=\sum_{n=46}^{50} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 150.73839 \mathrm{eV})}=\frac{15 e^{2}}{8 \pi \varepsilon_{0}(e 150.73839 \mathrm{eV})}=1.35392 a_{0} \tag{23.274}
\end{equation*}
$$

where $Z=51$ for antimony. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(S b, 5 s p^{3}\right)$ of the outer electron of the $S b 5 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(S b, 5 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{5 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.35392 a_{0}}=-10.04923 \mathrm{eV} \tag{23.275}
\end{equation*}
$$

During hybridization, the spin-paired $5 s$ electrons are promoted to the $S b 5 s p^{3}$ shell as paired electrons at the radius $r_{5 s p^{3}}$ of the $S b 5 s p^{3}$ shell. The energy for the promotion is the difference in the magnetic energy given by Eq. (15.15) at the initial radius of the $5 s$ electrons and the final radius of the $S b 5 s p^{3}$ electrons. From Eq. (10.102) with $Z=51$ and $n=48$, the radius $r_{48}$ of the Sb5s shell is:

$$
\begin{equation*}
r_{48}=1.23129 a_{0} \tag{23.276}
\end{equation*}
$$

Using Eqs. (15.15) and (23.276), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}}\left(\frac{1}{\left(r_{48}\right)^{3}}-\frac{1}{\left(r_{5 s p^{3}}\right)^{3}}\right)=8 \pi \mu_{0} \mu_{B}^{2}\left(\frac{1}{\left(1.23129 a_{0}\right)^{3}}-\frac{1}{\left(1.35392 a_{0}\right)^{3}}\right)=0.01519 \mathrm{eV} \tag{23.277}
\end{equation*}
$$

Using Eqs. (23.275) and (23.277), the energy $E\left(S b, 5 s p^{3}\right)$ of the outer electron of the $S b 5 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(S b, 5 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{5 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}}=-10.04923 \mathrm{eV}+0.01519 \mathrm{eV}=-10.03404 \mathrm{eV} \tag{23.278}
\end{equation*}
$$

For the $S b-C$ functional group, hybridization of the $2 s$ and $2 p$ AOs of each $C$ and the $5 s$ and $5 p$ AOs of each $S b$ to form single $2 s p^{3}$ and $5 s p^{3}$ shells, respectively, forms an energy minimum, and the sharing of electrons between the $C 2 s p^{3}$ and $S b 5 s p^{3}$ HOs to form a MO permits each participating orbital to decrease in radius and energy. In branched-chain alkyl stibines, the energy of antimony is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{2}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $C_{2}$ parameter. Then, the $C 2 s p^{3}$ HO has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $S b 5 s p^{3} \mathrm{HO}$ has an energy of $E\left(S b, 5 s p^{3}\right)=-10.03404 \mathrm{eV}$ (Eq. (23.278)). To meet the equipotential condition of the union of the $\mathrm{Sb}-\mathrm{C} \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $C_{2}$ of Eq. (15.61) for the $S b-C$-bond MO given by Eqs. (15.77), (15.79), and (13.430) is:

$$
\begin{equation*}
C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to Sb5sp}{ }^{3} \mathrm{HO}\right)=\frac{E\left(S b, 5 s p^{3}\right)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-10.03404 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.62921 \tag{23.279}
\end{equation*}
$$

The energy of the $\mathrm{Sb}-\mathrm{C}$-bond MO is the sum of the component energies of the $H_{2}$-type ellipsoidal MO given in Eq. (15.51) with $E(A O / H O)=E\left(S b, 5 s p^{3}\right)$ given by Eq. (23.278), and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is zero in order to match the energies of the carbon and antimony HOs.

The symbols of the functional groups of branched-chain alkyl stibines are given in Table 123.85. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl stibines are given in Tables 23.86, 23.87, and 23.88, respectively. The total energy of each alkyl stibine given in Table 23.89 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 23.88 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl stibines determined using Eqs. (15.88-15.117) are given in Table 23.90. The color scale, charge-density of exemplary alkyl stibine, triphenylstibine, comprising atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 23.18.

Figure 23.18. Color scale, charge-density of triphenylstibine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei.

## ALKYL BISMUTHS ( $\left.\left(C_{n} H_{2 n+1}\right)_{3} B i, n=1,2,3,4,5 \ldots \infty\right)$

The alkyl bismuths, $\left(C_{n} H_{2 n+1}\right)_{3} B i$, comprise a $\mathrm{Bi}-\mathrm{C}$ functional group. The alkyl portion of the alkyl bismuth may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of each chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl bismuths are equivalent to those in branched-chain alkanes. The $B i-C$ group may further join the $B i 6 s p^{3} \mathrm{HO}$ to an aryl HO .

As in the case of phosphorous, arsenic, and antimony, the bonding in the bismuth atom involves $s p^{3}$ hybridized orbitals formed, in this case, from the $6 p$ and $6 s$ electrons of the outer shells. The $B i-C$ bond forms between $B i 6 s p^{3}$ and $C 2 s p^{3}$ HOs to yield bismuths. The semimajor axis $a$ of the $B i-C$ functional group is solved using Eq. (15.51). Using the semimajor axis and the relationships between the prolate spheroidal axes, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in the Organic Molecular Functional Groups and Molecules section.

The energy of bismuth is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). A minimum energy is achieved while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical ( $O H$ ) section with hybridization of the bismuth atom such that in Eqs. (15.51) and (15.61), the sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $B i 6 s p^{3}$ shell as in the case of the corresponding phosphines, arsines, and stibines.

The $B i$ electron configuration is $[X e] 6 s^{2} 4 f^{14} 5 d^{10} 6 p^{3}$ corresponding to the ground state ${ }^{4} S_{3 / 2}$, and the $6 s p^{3}$ hybridized orbital arrangement after Eq. (13.422) is:

\[

\]

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the five electrons. The sum $E_{T}\left(B i, 6 s p^{3}\right)$ of experimental energies [1] of $B i, B i^{+}, B i^{2+}, B i^{3+}$, and $B i^{4+}$ is:

$$
\begin{equation*}
E_{T}\left(B i, 6 s p^{3}\right)=56.0 \mathrm{eV}+45.3 \mathrm{eV}+25.56 \mathrm{eV}+16.703 \mathrm{eV}+7.2855 \mathrm{eV}=150.84850 \mathrm{eV} \tag{23.281}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{6 s p^{3}}$ of the Bi $6 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$
\begin{equation*}
r_{6 s p^{3}}=\sum_{n=78}^{82} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 150.84850 \mathrm{eV})}=\frac{15 e^{2}}{8 \pi \varepsilon_{0}(e 150.84850 \mathrm{eV})}=1.35293 a_{0} \tag{23.282}
\end{equation*}
$$

where $Z=83$ for bismuth. Using Eq. (15.14), the Coulombic energy $E_{\text {Coulomb }}\left(B i, 6 s p^{3}\right)$ of the outer electron of the $B i 6 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(B i, 6 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{6 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.35293 a_{0}}=-10.05657 \mathrm{eV} \tag{23.283}
\end{equation*}
$$

During hybridization, the spin-paired $6 s$ electrons are promoted to the $B i 6 s p^{3}$ shell as paired electrons at the radius $r_{6 s p^{3}}$ of the Bi6sp ${ }^{3}$ shell. The energy for the promotion is the difference in the magnetic energy given by Eq. (15.15) at the initial radius of the $6 s$ electrons and the final radius of the $B i 6 s p^{3}$ electrons. From Eq. (10.102) with $Z=83$ and $n=80$, the radius $r_{80}$ of the Bi6s shell is:

$$
\begin{equation*}
r_{80}=1.20140 a_{0} \tag{23.284}
\end{equation*}
$$

Using Eqs. (15.15) and (23.284), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}}\left(\frac{1}{\left(r_{80}\right)^{3}}-\frac{1}{\left(r_{6 s p^{3}}\right)^{3}}\right)=8 \pi \mu_{0} \mu_{B}^{2}\left(\frac{1}{\left(1.20140 a_{0}\right)^{3}}-\frac{1}{\left(1.35293 a_{0}\right)^{3}}\right)=0.01978 \mathrm{eV} \tag{23.285}
\end{equation*}
$$

Using Eqs. (23.283) and (23.285), the energy $E\left(B i, 6 s p^{3}\right)$ of the outer electron of the Bi6sp ${ }^{3}$ shell is:

$$
\begin{equation*}
E\left(B i, 6 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {ssp }}{ }^{3}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}}\left(\frac{1}{\left(r_{80}\right)^{3}}-\frac{1}{\left(r_{6 s p^{3}}\right)^{3}}\right)=-10.05657 \mathrm{eV}+0.01978 \mathrm{eV}=-10.03679 \mathrm{eV} \tag{23.286}
\end{equation*}
$$

Next, consider the formation of the $B i-L$-bond MO of bismuth compounds wherein $L$ is a very stable ligand and each bismuth atom has a $B i 6 s p^{3}$ electron with an energy given by Eq. (23.286). The total energy of the state of each bismuth atom is given by the sum over the five electrons. The sum $E_{T}\left(B i_{B i-L}, 6 s p^{3}\right)$ of energies of $B i 6 s p^{3}$ (Eq. (23.286)), $B i^{+}, B i^{2+}, B i^{3+}$, and $B i^{4+}$ is:

$$
\begin{align*}
E_{T}\left(B i_{B i-L}, 6 s p^{3}\right) & =-\left(56.0 \mathrm{eV}+45.3 \mathrm{eV}+25.56 \mathrm{eV}+16.703 \mathrm{eV}+E\left(B i, 6 s p^{3}\right)\right)  \tag{23.287}\\
& =-(56.0 \mathrm{eV}+45.3 \mathrm{eV}+25.56 \mathrm{eV}+16.703 \mathrm{eV}+10.03679 \mathrm{eV})=-153.59979 \mathrm{eV}
\end{align*}
$$

where $E\left(B i, 6 s p^{3}\right)$ is the sum of the energy of $B i,-7.2855 \mathrm{eV}$, and the hybridization energy.
A minimum energy is achieved while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical ( OH ) section with the donation of electron density from the participating $B i 6 s p^{3} \mathrm{HO}$ to each $\mathrm{Bi}-L$-bond MO. Consider the case wherein each Bi6sp ${ }^{3}$ HO donates an excess of $25 \%$ of its electron density to the $B i-L$-bond MO to form an energy minimum. By considering this electron redistribution in the bismuth molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, in general terms, the radius $r_{B i-L 6 s p^{3}}$ of the Bi6sp ${ }^{3}$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$
\begin{equation*}
r_{B i-L 6 s p^{3}}=\left(\sum_{n=78}^{82}(Z-n)-0.25\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 153.59979 \mathrm{eV})}=\frac{14.75 e^{2}}{8 \pi \varepsilon_{0}(\mathrm{el} 53.59979 \mathrm{eV})}=1.30655 a_{0} \tag{23.288}
\end{equation*}
$$

Using Eqs. (15.19) and (23.288), the Coulombic energy $E_{C o u l o m b}\left(B i_{B i-L}, 6 s p^{3}\right)$ of the outer electron of the $B i 6 s p^{3}$ shell is:

$$
\begin{align*}
E_{\text {Coulomb }}\left(B i_{B i-L}, 6 s p^{3}\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{B i-L 6 s p^{3}}} \\
& =\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.30655 a_{0}}  \tag{23.289}\\
& =-10.41354 \mathrm{eV}
\end{align*}
$$

During hybridization, the spin-paired $6 s$ electrons are promoted to the $B i 6 s p^{3}$ shell as paired electrons at the radius $r_{6 s p^{3}}$ of the $B i 6 s p^{3}$ shell. The energy for the promotion is the difference in the magnetic energy given by Eq. (15.15) at the initial radius of the $6 s$ electrons and the final radius of the $B i 6 s p^{3}$ electrons. Using Eqs. (23.285) and (23.289), the energy $E\left(B i_{B i-L}, 6 s p^{3}\right)$ of the outer electron of the $B i 6 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(B i_{B i-L}, 6 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{B i-L 6 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{80}\right)^{3}}=-10.41354 \mathrm{eV}+0.01978 \mathrm{eV}=-10.39377 \mathrm{eV} \tag{23.290}
\end{equation*}
$$

Thus, $E_{T}\left(B i-L, 6 s p^{3}\right)$, the energy change of each $B i 6 s p^{3}$ shell with the formation of the $B i-L$-bond MO is given by the difference between Eq. (23.290) and Eq. (23.286).

$$
\begin{equation*}
E_{T}\left(B i-L, 6 s p^{3}\right)=E\left(B i_{B i-L}, 6 s p^{3}\right)-E\left(B i, 6 s p^{3}\right)=-10.39377 \mathrm{eV}-(-10.03679 \mathrm{eV})=-0.35698 \mathrm{eV} \tag{23.291}
\end{equation*}
$$

Next, consider the formation of the $B i-C$-bond MO by bonding with a carbon having a $C 2 s p^{3}$ electron with an energy given by Eq. (14.146). The total energy of the state is given by the sum over the five electrons. The sum $E_{T}\left(C_{\text {ethane }}, 2 s p^{3}\right)$ of calculated energies of $C 2 s p^{3}, C^{+}, C^{2+}$, and $C^{3+}$ from Eqs. (10.123), (10.113-10.114), (10.68), and (10.48), respectively, is:

$$
\begin{align*}
E_{T}\left(C_{\text {ethane }}, 2 s p^{3}\right) & =-\left(64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+E\left(C, 2 s p^{3}\right)\right)  \tag{23.292}\\
& =-(64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+14.63489 \mathrm{eV})=-151.61569 \mathrm{eV}
\end{align*}
$$

where $E\left(C, 2 s p^{3}\right)$ is the sum of the energy of $C,-11.27671 \mathrm{eV}$, and the hybridization energy.
The sharing of electrons between the $B i 6 s p^{3} \mathrm{HO}$ and $C 2 s p^{3} \mathrm{HOs}$ to form a $B i-C$-bond MO permits each participating hybridized orbital to decrease in radius and energy. A minimum energy is achieved while satisfying the potential, kinetic, and orbital energy relationships, when the $B i 6 s p^{3} \mathrm{HO}$ donates, and the $C 2 s p^{3} \mathrm{HO}$ receives, excess electron density equivalent to an electron within the $B i-C$-bond MO. By considering this electron redistribution in the alkyl bismuth molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{B i-C 2 s p^{3}}$ of the $C 2 s p^{3}$ shell of the $B i-C$-bond MO may be calculated from the Coulombic energy using Eqs. (15.18) and (23.292):

$$
\begin{equation*}
r_{B i-C 2 s p^{3}}=\left(\sum_{n=2}^{5}(Z-n)+1\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 151.61569 \mathrm{eV})}=\frac{11 e^{2}}{8 \pi \varepsilon_{0}(e 151.61569 \mathrm{eV})}=0.98713 a_{0} \tag{23.293}
\end{equation*}
$$

Using Eqs. (15.19) and (23.293), the Coulombic energy $E_{\text {Coulomb }}\left(C_{B i-C}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(C_{B i-C}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{B i-C 2 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.98713 a_{0}}=-13.78324 \mathrm{eV} \tag{23.294}
\end{equation*}
$$

During hybridization, the spin-paired $2 s$ electrons are promoted to the $C 2 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (14.145). Using Eqs. (14.145) and (23.294), the energy $E\left(C_{B i-C}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(C_{B i-C}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{B i-C 2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-13.78324 \mathrm{eV}+0.19086 \mathrm{eV}=-13.59238 \mathrm{eV} \tag{23.295}
\end{equation*}
$$

Thus, $E_{T}\left(B i-C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell with the formation of the $B i-C$-bond MO is given by the difference between Eq. (23.295) and Eq. (14.146).

$$
\begin{equation*}
E_{T}\left(B i-C, 2 s p^{3}\right)=E\left(C_{B i-C}, 2 s p^{3}\right)-E\left(C, 2 s p^{3}\right)=-13.59238 \mathrm{eV}-(-14.63489 \mathrm{eV})=1.04251 \mathrm{eV} \tag{23.296}
\end{equation*}
$$

Now, consider the formation of the $B i-L$-bond MO of bismuth compounds wherein $L$ is a ligand including carbon. For the $B i-C$ functional group, hybridization of the $2 s$ and $2 p$ AOs of each $C$ and the $6 s$ and $6 p$ AOs of each Bi to form single $2 s p^{3}$ and $6 s p^{3}$ shells, respectively, forms an energy minimum, and the sharing of electrons between the $C 2 s p^{3}$ and Bi6sp ${ }^{3}$ HOs to form a MO permits each participating orbital to decrease in radius and energy. In branched-chain alkyl bismuths, the energy of bismuth is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, the energy matching condition is determined by the $c_{2}$ and $C_{2}$ parameters in Eq. (15.61). Then, the $C 2 s p^{3}$ HO has an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $B i 6 s p^{3} \mathrm{HO}$ has an energy of $E\left(B i, 6 s p^{3}\right)=-10.03679 \mathrm{eV}$ (Eq. (23.286)). To meet the equipotential condition of the union of the $B i-C H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factors $c_{2}$ and $C_{2}$ of Eq. (15.61) for the $\mathrm{Bi}-\mathrm{C}$-bond MO given by Eqs. (15.77) are:

$$
\begin{equation*}
c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Bi} 6 s p^{3} \mathrm{HO}\right)=C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to Bi } 6 s p^{3} \mathrm{HO}\right)=\frac{E\left(\mathrm{Bi}, 6 s p^{3}\right)}{E\left(C, 2 s p^{3}\right)}=\frac{-10.03679 \mathrm{eV}}{-14.63489 \mathrm{eV}}=0.68581 \tag{23.297}
\end{equation*}
$$

The energy of the $\mathrm{Bi}-\mathrm{C}$-bond MO is the sum of the component energies of the $H_{2}$-type ellipsoidal MO given in Eq. (15.51) with $E(A O / H O)=E\left(B i, 6 s p^{3}\right)$ given by Eq. (23.286), and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} \cdot A O\right)$ is $E_{T}\left(B i-C, 2 s p^{3}\right)$ (Eq. (23.296)) in order to match the energies of the carbon and bismuth HOs.

The symbols of the functional groups of branched-chain alkyl bismuths are given in Table 23.91. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl bismuths are given in Tables 23.92, 23.93, and 23.94, respectively. The total energy of each alkyl bismuth given in Table 23.95 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 23.94 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl bismuths determined using Eqs. (15.88-15.117) are given in Table 23.96. The color scale, charge-density of exemplary alkyl bismuth, triphenylbismuth, comprising atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 23.19.

Figure 23.19. Color scale, charge-density of triphenylbismuth showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei.

## SUMMARY TABLES OF ORGANOMETALLIC AND COORDINATE MOLECULES

The bond energies, calculated using closed-form equations having integers and fundamental constants only for classes of molecules whose designation is based on the main functional group, are given in the following tables with the experimental values.

Table 23.97.1. Summary results of organoaluminum compounds.

| Formula | Name | Calculated <br> Total Bond <br> Energy $(\mathrm{eV})$ | Experimental <br> Total Bond <br> Energy $(\mathrm{eV})$ | Relative <br> Error |
| :--- | :--- | :---: | :---: | :---: |
| $\mathrm{C}_{2} \mathrm{H}_{7} \mathrm{Al}$ | dimethylaluminum hydride | 34.31171 | $34.37797^{\mathrm{a}}[11]$ | 0.00193 |
| $\mathrm{C}_{3} \mathrm{H}_{9} \mathrm{Al}$ | trimethyl aluminum | 47.10960 | $46.95319[10]$ | -0.00333 |
| $\mathrm{C}_{4} \mathrm{H}_{11} \mathrm{Al}$ | diethylaluminum hydride | 58.62711 | $60.10948^{\mathrm{b}}[10]$ | 0.02466 |
| $\mathrm{C}_{6} \mathrm{H}_{15} \mathrm{Al}$ | triethylaluminum hydride | 83.58270 | $83.58176[10]$ | -0.00001 |
| $\mathrm{C}_{6} \mathrm{H}_{15} \mathrm{Al}$ | di-n-propylaluminum hydride | 82.94251 | $84.40566^{\mathrm{b}}[10]$ | 0.01733 |
| $\mathrm{C}_{9} \mathrm{H}_{21} \mathrm{Al}$ | tri-n-propyl aluminum | 120.05580 | $121.06458^{\mathrm{b}}[10]$ | 0.00833 |
| $\mathrm{C}_{8} \mathrm{H}_{19} \mathrm{Al}$ | di-n-butylaluminum hydride | 107.25791 | $108.71051^{\mathrm{b}}[10]$ | 0.01336 |
| $\mathrm{C}_{8} \mathrm{H}_{19} \mathrm{Al}$ | di-isobutylaluminum hydride | 107.40303 | $108.77556^{\mathrm{b}}[10]$ | 0.01262 |
| $\mathrm{C}_{12} \mathrm{H}_{27} \mathrm{Al}$ | tri-n-butyl aluminum | 156.52890 | $157.424299^{\mathrm{b}}[10]$ | 0.00569 |
| $\mathrm{C}_{12} \mathrm{H}_{27} \mathrm{Al}$ | tri-isobutyl aluminum | 156.74658 | $157.58908^{\mathrm{b}}[10]$ | 0.00535 |

[^46]Table 23.97.2. Summary results of scandium coordinate compounds.

| Formula | Name | Calculated <br> Total Bond <br> Energy (eV) | Experimental <br> Total Bond <br> Energy (eV) | Relative Error |

Dr. Mills has advanced the field generally known as Quantum Mechanics by deriving a new atomic theory of Classical Physics (CP) from first principles, which unifies Maxwell's Equations, Newton's Laws, and Einstein's General and Special Relativity. The central feature is that physical laws hold over all scales, from the scale of subatomic particles to that of the cosmos.
Quantum Mechanics has remained mysterious to all who have encountered it. Whereas Schrödinger postulated a boundary condition $\Psi \rightarrow 0$ as $r \rightarrow \infty$ resulting in a purely mathematical model of the hydrogen atom, CP was derived from known physics, i.e. Maxwell's Equations. Under special conditions, an extended distribution of charge may accelerate without radiating energy. This leads to a physical model of subatomic particles, atoms, and molecules. Equations are closed-form solutions containing fundamental constants only and agree with experimental observations.

From two basic equations, the key building blocks of organic chemistry have been solved, allowing the true physical structure and parameters of an infinite number of organic molecules up to infinite length and complexity to be obtained. These equations were also applied to bulk forms of matter, such as the allotropes of carbon, the solid bond of silicon and the semiconductor bond; as well as fundamental forms of matter such as the ionic bond and the metallic bond; and major fields of chemistry such as that of silicon, tin, aluminum, boron, coordinate compounds and organometallics.

Further, the Schwarzschild Metric is derived by applying Maxwell's Equations to electromagnetic and gravitational fields at particle production. This modifies General Relativity to include the conservation of spacetime and gives the origin of gravity, the families and masses of fundamental particles, the acceleration of the expansion of the Universe (predicted by Dr. Mills in 1995 and since confirmed experimentally), and overturns the Big Bang model of the origin of the Universe.

"Mills' theory explains the answers to some very old scientific questions, such as 'what happens to a photon upon absorption' and some very modern ones, such as 'what is dark matter.' ...Lastly, Mills has made an extremely important contribution to the philosophy of science. He has reestablished cause and effect as the basic principle of science."

Dr. John J. Farrell, former Chair of the Dept. of Chemistry, Franklin \& Marshall College
"Mills' ingenious way of thinking creates in different physical areas astonishing results with fascinating mathematical simplicity and harmony. And his theory is strongly supported by the fact that nearly all these results are in comfortable accordance with experimental findings, sometimes with breathtaking accuracy."

Dr Günther Landvogt, Retired Scientist, Philips Research Lab
"Dr. Mills has apparently completed Einstein's quest for a unified field theory... without largesse from the US Government, and without the benediction of the US scientific priesthood."

Shelby T. Brewer, former Assistant Secretary of Energy, former CEO of ABB Combustion Engineering, MS/Ph.D. MIT - Nuclear Engineering.
"Mills proposes such a basic approach to quantum theory that it deserves considerably more attention from the general scientific community than it has received so far. The new theory appears to be a realization of Einstein's vision and a fitting closure of the "Quantum Century" that started in 1900..."

Dr. Reinhart Engelmann, Professor of Electrical Engineering, Oregon Graduate Institute of Science and Technology

Dr. Randell Mills holds a Doctor of Medicine degree from Harvard, a BA degree in Chemistry from Franklin and Marshall College, and studied Electrical Engineering at MIT. He is President, Chairman and CEO of Brilliant Light Power, Inc.

## TABLE OF CONTENTS

VOLUME 3 COLLECTIVE PHENOMENA, HIGH-ENERGY PHYSICS, \& COSMOLOGY
24. Statistical Mechanics ..... 1409
24.1 Three Different Kinds of Atomic-Scale Statistical Distributions ..... 1409
24.1.1 Maxwell-Boltzmann ..... 1410
24.1.2 Bose-Einstein ..... 1411
24.1.3 Fermi-Dirac. ..... 1411
24.2 Application of Maxwell-Boltzmann Statistics to Model Molecular Energies in an Ideal Gas. ..... 1414
24.3 Application of Bose-Einstein Statistics to Model Blackbody Radiation ..... 1417
24.3.1 Planck Radiation Law ..... 1418
24.4 Application of Bose-Einstein Statistics to Model Specific Heats of Solids ..... 1421
24.5 Application of Fermi-Dirac Statistics to Model Free Electrons in a Metal ..... 1422
24.5.1 Electron-Energy Distribution. ..... 1423
References ..... 1424
25. Superconductivity ..... 1425
Box 25.1 Fourier Transform of the System Function ..... 1425
References ..... 1428
25.1 Band-Pass Filter ..... 1428
25.2 Critical Temperature, $\mathrm{T}_{\mathrm{c}}$ ..... 1432
25.2.1 $\quad \mathrm{T}_{\mathrm{C}}$ for Conventional Three Dimensional Metallic Superconductors ..... 1432
25.2.2 $\quad T_{c}$ for One, Two, or Three Dimensional Ceramic Oxide Superconductors ..... 1432
25.3 Josephson Junction, Weak Link ..... 1432
References ..... 1433
26. Quantum Hall Effect ..... 1435
26.1 General Considerations ..... 1435
26.2 Integral Quantum Hall Effect. ..... 1436
26.3 Fractional Quantum Hall Effect ..... 1439
References ..... 1440
27. Aharonov-Bohm Effect. ..... 1441
References ..... 1443
28. Creation of Matter from Energy ..... 1445
29. Pair Production ..... 1449
References ..... 1452
30. Positronium ..... 1453
30.1 Excited State Energies ..... 1454
30.2 Hyperfine Structure ..... 1455
References ..... 1457
31. Relativity ..... 1459
31.1 Basis of a Theory of Relativity ..... 1459
31.2 Lorentz Transformations ..... 1462
31.3 Time Dilation ..... 1462
31.3.1 The Relativity of Time ..... 1462
31.4 The Relativity Principle and the Covariance of Equations in Galilean or Euclidean Spacetime and Riemann Spacetime ..... 1464
References ..... 1468
32. Gravity ..... 1469
32.1 Quantum Gravity of Fundamental Particles ..... 1469
32.2 Particle Production ..... 1477
Box 32.1 Definition of Time Unit Sec, and Calculation and Measurement of Observables Over All Scales Thereupon ..... 1479
Box 32.2 Relationships Between the Earth Mean Solar Day Definition of the Second, the Definition of Sec Based on Pair Production and its Effect on Spacetime, and the Definition of Sec and the Fundamental Constants ..... 1480
32.3 Orbital Mechanics ..... 1482
32.4 Relativistic Corrections of Newtonian Mechanics and Newtonian Gravity ..... 1483
32.5 Precession of the Perihelion ..... 1484
32.6 Deflection of Light ..... 1486
32.7 Cosmology ..... 1488
32.8 Failed Cosmological Predictions Reveal Einstein’s Incorrect Physical Basis of General Relativity ..... 1490
32.9 Cosmology Based on the Relativistic Effects of Matter/Energy Conversion on Spacetime ..... 1494
32.9.1 The Arrow of Time and Entropy ..... 1494
32.9.2 The Arrow of Time ..... 1494
32.9.3 The Expanding Universe and the Microwave Background ..... 1495
32.9.4 The Period of Oscillation Based on Closed Propagation of Light ..... 1498
32.9.5 Equations of the Evolution of the Universe ..... 1498
Box 32.3 Simplified Set of Cosmological Equations ..... 1505
32.10 Composition of the Universe ..... 1508
32.11 Power Spectrum of the Cosmos ..... 1514
32.12 The Differential Equation of the Radius of the Universe ..... 1515

## Chapter 24

## STATISTICAL MECHANICS

Large systems of particles are ubiquitous in nature. The physics of each particle of a large system is determined by physical laws given its initial conditions and history. However, the amount of information to follow even 2 grams of hydrogen gas having Avogadro's number of molecules ( $N_{A}=6.022045 \times 10^{23} \mathrm{~mol}^{-1}$ ) is overwhelming. Statistical models typically deal with insufficient information for an underlying deterministic macrosystem such as the determination of an average property of a population with the accuracy only limited by the number of independent samples ${ }^{1}$. Fortunately for the cases of atomic systems, it is also possible to determine the bulk properties of many systems using statistical models. The modeling of aggregate behavior of a large ensemble of atoms, electrons, or photons obeying classical physics such as molecules in a gas, photons in a cavity, and free electrons in a metal is the branch of physics called statistical mechanics. Statistical mechanics gives state properties of a system of many particles that are a manifestation of the properties of the particles themselves. The necessity to be concerned with the actual motions and interactions of individual particles is avoided. Instead, such models give predictions for the probability that the particle has a certain amount of energy at a certain moment. It gives statistical distributions for all of the particles rather than the exact value for a specific particle.

## THREE DIFFERENT KINDS OF ATOMIC-SCALE STATISTICAL DISTRIBUTIONS [5]

It was shown in the State Lifetimes and Line Intensities section, that a mean lifetime arises due to the superposition of transitions over an ensemble of individual atoms. Each atom has an exact lifetime due to an exact transition involving specific initial, final, and any intermediate $\ell, m$ states and the corresponding exact photon in space relative to the states. The mean lifetime arises from the mean current given by Eq. (2.87) and the spherical radiation field due to the superposition of emitted photons. Similarly, Maxwell's equations apply to macroscopic electromagnetic fields that are in actuality the superposition of quantized photons traveling at the speed of light. Furthermore, using Maxwell's equations, the reduced speed of light in a transparent medium can be shown to be due to the radiation from many induced dipoles that produce a single wave propagating at the reduced speed [6]. Thus, deterministic physics arises as the aggregate behavior of entities that also in turn obey deterministic physics. The same principle applies in the case of statistical mechanical models.

In previous sections, the exact nature of individual particles (e.g. atoms, electrons, and photons) were solved. The interactions of two separate individual particles demonstrated three types of behavior that are correctly modeled by three types of corresponding statistical models. Each statistical model with a corresponding probability distribution function is based on the properties of the particle and their corresponding interactions.

According to statistical thermodynamics [7], a macroscopic thermodynamic system is viewed as an assembly of myriad submicroscopic entities in ever changing quantum states. Consider the number of distinct ways that a set number of energy

[^47]quanta can be distributed between a set number of energy levels each called a microstate. The total number of microstates $W$ associated with any configuration involving $N$ distinguishable units is
\[

$$
\begin{equation*}
W=\frac{N!}{\left(\eta_{a}!\right)\left(\eta_{b}!\right) \cdots} \tag{24.1}
\end{equation*}
$$

\]

where $\eta_{a}$ represents the number of units assigned the same number of energy quanta (and, hence, occupying the same quantum number), and $\eta_{b}$ represents the number of units occupying some other quantum level. As the number of units increases, the total number of microstates skyrockets to unimaginable magnitudes. Thus, one can calculate that an assembly of 1000 localized harmonic oscillators sharing 1000 energy quanta possesses more than $10^{600}$ different microstates. This explosive expansion of the total number of microstates with increasing $N$ is a direct consequence of the mathematics of permutations, from which arises also a second consequence of no less importance. Statistical analysis shows that the emergence of a predominant configuration is characteristic of any assembly with a large number ( $N$ ) of units. Of the immense total number of microstates that can be assumed by a large assembly, an overwhelming proportion arises from one comparatively, small set of configurations centered on, and only minutely different from, the predominant configuration-with which they share an empirically identical set of macroscopic properties.

The first step in the program of statistical mechanics is to find a general expression for $W$ for the kind of particles being considered. Then $W$ is maximized subject to the conditions that the system consists of a fixed number of $N$ particles (except when they are photons or their acoustic equivalents called phonons where the total energy is conserved, but the number can change since the individual energies are given by Planck's equation, $E=h v$ ) and that the system contains a fixed amount of energy $E$ that is conserved in populating the conserved number of states where applicable. The result in each case is an expression for $n(\varepsilon)$, the number of particles with the energy $\varepsilon$, that has the form:

$$
\begin{equation*}
n(\varepsilon)=g(\varepsilon) f(\varepsilon) \tag{24.2}
\end{equation*}
$$

where $g(\varepsilon)=$ number of states of energy $\varepsilon$
$=$ statistical weight corresponding to energy $\varepsilon$
$f(\varepsilon)=$ distribution function
$=$ average number of particles in each state of energy $\varepsilon$
$=$ probability of occupancy of each state of energy $\varepsilon$
When a continuous rather than a discrete distribution of energies is involved, $g(\varepsilon)$ is replaced by $g(\varepsilon) d \varepsilon$, the number of states energies between $\varepsilon$ and $\varepsilon+d \varepsilon$.

Each of the three models is based upon the determination of the most probable way in which a certain total amount of energy $E$ is distributed among the $N$ members of a system of particles in thermal equilibrium at the absolute temperature $T$. Then, it is possible to statistically predict aggregate properties such as the number of particles having an energy $\varepsilon_{1}, \varepsilon_{2}$, and so on, based on the model. The particle interactions are assumed to be at thermal equilibrium between themselves and the walls of their container in the absence of strongly correlated motion. More than one particle state may have a certain energy $\varepsilon$. In the case of Maxwell-Boltzmann and Bose-Einstein statistics more than one particle may be in a certain state. In the case of FermiDirac statistics each particle must be in different state since Fermi-Dirac statistics treats particles such as electrons that spin pair. A fundamental assumption of all statistical mechanical models that is supported by experimentation and consistent with physical laws, is that the greater the number $W$ of different ways in which the particles can be arranged among the available states to yield a particular distribution of energies, the more probable the distribution. It is assumed that each state of a certain energy is equally likely to be occupied. The atomic scale distributions derived from deterministic, conditional probability theory [8] are:

MAXWELL-BOLTZMANN—identical, discrete particles such as molecules are separated and act independently such that they possess a continuum of momenta with exchange by the predominant interaction of collisional scattering. Atoms and molecules have exact dimensions as shown in the and One-Electron Atom section, Two-Electron Atoms section, Three- Through Twenty-Electron Atoms section, Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section, Polyatomic Molecular Ions and Molecules section, and More Polyatomic Molecules and Hydrocarbons section. Neutral particles such as atoms and molecules undergo one-on-one collisional interactions, which are conservative; otherwise, there is no correlation between the separated particles. Maxwell-Boltzmann statistics is used to model the aggregate properties of a gas at a given temperature. The corresponding Maxwell-Boltzmann distribution function states that the average number of particles $f_{M B}(\varepsilon)$ in a state of energy $\varepsilon$ in a system of particles at the absolute temperature $T$ is:

$$
\begin{equation*}
f_{M B}(\varepsilon)=A e^{-\varepsilon / k T} \tag{24.3}
\end{equation*}
$$

where value of $A$ depends of the number of particles in the system is and serves to scale the distribution to the number of particles and, $k=1.381 \times 10^{-23} \mathrm{~J} / \mathrm{K}=8.617 \times 10^{-5} \mathrm{eV} / \mathrm{K}$ is Boltzmann's constant.

BOSE-EINSTEIN—indistinguishable photons called bosons having $\hbar$ of angular momentum excite quantized energy levels of electron resonator cavities where superposition and conservation of angular momentum are obeyed. As shown in the Excited States of the One-Electron Atom (Quantization) and the Excited States of Helium sections, each bound electron is a resonator cavity, which traps single photons of discrete frequencies. Thus, photon absorption occurs as an excitation of a resonator mode. The angular momentum of the free space photon given by $\mathbf{m}=\int \frac{1}{8 \pi c} \operatorname{Re}\left[\mathbf{r} \times\left(\mathbf{E} \times \mathbf{B}^{*}\right)\right] d x^{4}=\hbar$ in the Photon section is conserved [9] for the solutions for the resonant photons and excited-state electron functions. The change in angular frequency of the electron is equal to the angular frequency of the resonant photon that excites the resonator cavity mode corresponding to the transition, and the energy is given by Planck's equation. An ensemble of a large number of photons in equilibrium with a material comprised of many electron states having resonant transitions excited by the photons may be correlated in order to conserve angular momentum. Certain solid materials have essentially a continuum of discrete excited states wherein excitation of any state increases the cross section for the absorption of additional photons of the same energy by changing the angular momentum of the electron during excitation to permit further excitation. In each case, the excited-state electron can undergo further transitions by resonant excitation with photons of the same energy, but different polarizations having the required angular momentum. An ensemble of a large number of photons in equilibrium, with such a solid material comprised of many electron states having correlated resonant transitions excited by the photons, gives rise to blackbody radiation. The statistics of this model is based on the physics that the presence of a particle in a certain quantum state increases the probability that other particles are to be found in the same state. Bose-Einstein statistics is used to model photons in equilibrium with a cavity to account for the spectrum of radiation from a blackbody. It is also used to model phonons in a solid. The corresponding Bose-Einstein distribution function states that the probability $f(\varepsilon)$ that a boson occupies a state of energy $\varepsilon$ in a system of particles at the absolute temperature $T$ is:

$$
\begin{equation*}
f_{B E}(\varepsilon)=\frac{1}{e^{\alpha} e^{\varepsilon / k T}-1} \tag{24.4}
\end{equation*}
$$

FERMI-DIRAC—identical, indistinguishable electrons called fermions occupy the lowest energy configuration as given in the Two Electron Atom section. The Pauli Exclusion Principle arises as a minimum of energy for interacting electrons each having a Bohr magneton of magnetic moment. Electrons pair as opposite mirror-image currents such that the occupation of one spin state by a first electron (e.g. $s=1 / 2$ ) causes a second to occupy the opposite spin state ( $s=-1 / 2$ ). Thus, the statistics of this model is based on physics that the presence of a particle in a certain state prevents any other particles from being in that state. Fermi-Dirac statistics is used to model the behavior of electrons in a metal to explain the ability of metals to conduct electricity. The corresponding Fermi-Dirac distribution function states that the probability $f(\varepsilon)$ that a fermion occupies a state of energy $\varepsilon$ in a system of particles at the absolute temperature $T$ is:

$$
\begin{equation*}
f_{F D}(\varepsilon)=\frac{1}{e^{\alpha} e^{\varepsilon / k T}+1} \tag{24.5}
\end{equation*}
$$

The quantity $\alpha$ depends on the properties of the particular system and may be a function of $T$.
The Maxwell-Boltzmann distribution function holds for systems of identical particles that can be distinguished one from another and there is no conditional-probability factor corresponding to the physics of the occupation of a given quantum state influencing the probability that other particles are found in the same state. In contrast, the -1 term in the denominator of Eq. (24.4) expresses the increased likelihood of multiple occupancy of an energy state by bosons compared with the likelihood for distinguishable particles such as molecules. The +1 term in the denominator in Eq. (24.5) is a consequence of the minimization of energy corresponding to spin pairing: no matter what the values of $\alpha, \varepsilon$, and $T, f(\varepsilon)$ can never exceed one. In both cases, when $\varepsilon \gg k T$, the functions $f(\varepsilon)$ approach that of the Maxwell-Boltzmann statistics, Eq. (24.3). Figure 24.1 is a comparison of the three distribution functions for $\alpha=-1$. For a given value of $\frac{\varepsilon}{k T}, f_{B E}(\varepsilon)$, which models bosons (photons and phonons), is always greater than $f_{M B}(\varepsilon)$, and $f_{F D}(\varepsilon)$, which models fermions (electrons), is always smaller.

From Eq. (24.5), $f_{F D}(\varepsilon)=\frac{1}{2}$ when the energy is:

$$
\begin{equation*}
\varepsilon_{F}=-\alpha k T \tag{24.6}
\end{equation*}
$$

This energy defined as the Fermi energy, has significance in analyzing the behavior of a system of fermions, such as the conduction electrons in a metal. The Fermi-Dirac distribution function, expressed in terms of $\varepsilon_{F}$ is:

$$
\begin{equation*}
f_{F D}(\varepsilon)=\frac{1}{e^{\left(\varepsilon-\varepsilon_{F}\right) / k T}+1} \tag{24.7}
\end{equation*}
$$

Figure 24.1. A comparison of the three statistical functions that give the probability of occupancy of a state of energy $\varepsilon$ at the absolute temperature $T$ for $\alpha=-1$. The Maxwell-Boltzmann is pure exponential. The Bose-Einstein function is always higher and the Fermi-Dirac function is always lower.

The significance of the Fermi energy can be appreciated by comparing the occupancy of the states a system of fermions at $T=0$ whose energies are less than $\varepsilon_{F}$ with those that are greater than $\mathcal{\varepsilon}_{F}$ :

$$
\begin{align*}
& T=0, \varepsilon<\varepsilon_{F}: f_{F D}(\varepsilon)=\frac{1}{e^{\left(\varepsilon-\varepsilon_{F}\right) / k T}+1}=\frac{1}{e^{-\infty}+1}=\frac{1}{0+1}=1  \tag{24.8}\\
& T=0, \varepsilon>\varepsilon_{F}: f_{F D}(\varepsilon)=\frac{1}{e^{\left(\varepsilon-\varepsilon_{F}\right) / k T}+1}=\frac{1}{e^{\infty}+1}=0
\end{align*}
$$

At absolute zero, all energy states up to $\varepsilon_{F}$ are occupied, but none above $\varepsilon_{F}$ as shown in Figure 24.2 for $T=0$. As given in the Free Electrons in a Metal Section (Eq. (24.60)), the Fermi energy $\varepsilon_{F}$ of a system containing $N$ fermions can calculated by filling up its energy states with the $N$ particles in order of increasing energy starting from $\varepsilon=0$. The highest state to be occupied will then have the energy $\varepsilon=\varepsilon_{F}$.

The distribution functions for fermions at $T=0, T=0.1 \frac{\varepsilon_{F}}{k}$, and $T=1.0 \frac{\varepsilon_{F}}{k}$ are shown in Figure 24.2. As the temperature is increased above $T=0$ with $0<k T<\varepsilon_{F}$, fermions shift their population of states from those just below $\varepsilon_{F}$ to states just above it as shown in Figure 24.2 for $T=0.1 \frac{\varepsilon_{F}}{k}$. At higher temperatures, even fermions in the lowest states will begin to be excited to higher ones, so $f_{F D}(0)$ will drop below 1. In these circumstances $f_{F D}(\varepsilon)$ will assume a shape like that the lowest curve in Figure 24.2 corresponding to $T=1.0 \frac{\varepsilon_{F}}{k}$. The properties of the three distribution functions are summarized in Table 24.1 wherein to obtain the actual number $n(\varepsilon)$ of particles with an energy $\varepsilon$, the functions $f(\varepsilon)$ are multiplied by $g(\varepsilon)$, the number of states of energy $(\varepsilon)$ :

$$
\begin{equation*}
n(\varepsilon)=g(\varepsilon) f(\varepsilon) \tag{24.9}
\end{equation*}
$$

Figure 24.2. Distribution function for fermions at three different temperatures. At $T=0$, all the energy states up to the Fermi energy $\varepsilon_{F}$ are occupied. At low temperature $\left(T=0.1 \frac{\varepsilon_{F}}{k}\right.$ ), some fermions will leave states just below $\varepsilon_{F}$ and move into states just above $\varepsilon_{F}$. At a higher temperature $\left(T=1.0 \frac{\varepsilon_{F}}{k}\right)$, fermions from any state below $\varepsilon_{F}$ may move into states above $\varepsilon_{F}$.

Table 24.1. The Three Statistical Distribution Functions

|  | Maxwell-Boltzmann | Bose-Einstein | Fermi-Dirac |
| :---: | :---: | :---: | :---: |
| Applies to systems of | Identical, distinguishable particles | Identical, indistinguishable particles that do not spin pair | Identical, indistinguishable particles that spin pair |
| Categories of particles | Collisional | Bosons | Fermions |
| Properties of particles | Any spin | Spin 0, 1, 2, | Spin $\frac{1}{2}, \frac{3}{2}, \frac{5}{2}$ |
| Examples | Molecules of gas | Photons in a cavity; phonons in a solid; liquid helium at low temperatures | Free electrons in a metal |
| Distribution function (number of particles in each state of energy $\varepsilon$ at the temperature T) | $f_{M B}(\varepsilon)=A e^{-\varepsilon / k T}$ | $f_{B E}(\varepsilon)=\frac{1}{e^{\alpha} e^{\varepsilon / k T}-1}$ | $f_{F D}(\varepsilon)=\frac{1}{e^{\left(\varepsilon-\varepsilon_{F}\right) / k T}+1}$ |
| Properties of distribution | No limit to number of particles per state | No limit to number of particles per state; more particles per state than $f_{M B}$ at low energies; approaches $f_{M B}$ at high energies | Never more than 1 particle per state; fewer particles per state than $f_{M B}$ at low energies; approaches $f_{M B}$ at high energies |

## APPLICATION OF MAXWELL-BOLTZMANN MOLECULAR ENERGIES IN AN IDEAL GAS

Combining Eqs. (24.2) and (24.3) gives us the number $n(\varepsilon)$ of identical, distinguishable particles in an assembly at the temperature $T$ that have the energy $\varepsilon$ :

$$
\begin{equation*}
n(\varepsilon)=A g(\varepsilon) e^{-\varepsilon / k T} \tag{24.10}
\end{equation*}
$$

Eq. (24.3) predicts that $f_{M B}(\varepsilon)$ decreases with $\varepsilon$ and increases with increasing $T$ consistent with observations. A more definite test of the validity of Eq. (24.3) including the $1 / k T$ factor in the exponent is to use it to calculate the total internal energy $E$ of a system of particles for which $E$ is known. An appropriate test system is a sample of an ideal gas that contains $N$ molecules. The elementary kinetic theory of gases shows that the ideal-gas law will have the correct form $P V=N k T$ only if the average molecular kinetic energy is $\frac{3}{2} k T$, so that the total molecular energy must be $E=\frac{3}{2} N k T$. As shown by Eq. (24.24), Eq. (24.3) does give this result validating the model, which is developed next.

The translational motion of gas molecules is continuous, and the total number of molecules $N$ in a sample is usually very large. Therefore, a continuous distribution of molecular energies is used instead of the discrete set $\varepsilon_{1}, \varepsilon_{2}, \varepsilon_{3}, \ldots$. If $n(\varepsilon) d \varepsilon$ is the number of molecules whose energies lie between $\varepsilon$ and $\varepsilon+d \varepsilon$, Eq. (24.3) can be written:

$$
\begin{equation*}
n(\varepsilon) d \varepsilon=[g(\varepsilon) d \varepsilon][f(\varepsilon)]=A g(\varepsilon) e^{-\varepsilon / k T} d \varepsilon \tag{24.11}
\end{equation*}
$$

To find $g(\varepsilon) d \varepsilon$, the number of states that have energies between $\varepsilon$ and $\varepsilon+d \varepsilon$, first consider that a molecule of energy $\varepsilon$ has a momentum $\mathbf{p}$ whose magnitude $p$ is specified by:

$$
\begin{equation*}
p=\sqrt{2 m \varepsilon}=\sqrt{p_{x}^{2}+p_{y}^{2}+p_{z}^{2}} \tag{24.12}
\end{equation*}
$$

Each set of momentum components $p_{x}, p_{y}, p_{z}$ specifies a different state of motion. Further consider a momentum space whose coordinate axes are $p_{x}, p_{y}, p_{z}$, as in Figure 24.3. The number of states $g(p) d p$ with momenta whose magnitudes are between $p$ and $p+d p$ are proportional to the volume of a spherical shell in momentum space $p$ in radius and $d p$ thick, which is $4 \pi p^{2} d p$. Hence

$$
\begin{equation*}
g(p) d p=B p^{2} d p \tag{24.13}
\end{equation*}
$$

where $B$ is some constant. Since each momentum magnitude $p$ corresponds to a single energy $\varepsilon$, the number of energy states $g(\varepsilon) d \varepsilon$ between $\varepsilon$ and $\varepsilon+d \varepsilon$ is the same as the number of momentum states $g(p) d p$ between $p$ and $p+d p$. Thus, Eq. (24.13) becomes:

$$
\begin{equation*}
g(\varepsilon) d \varepsilon=B p^{2} d p \tag{24.14}
\end{equation*}
$$

Figure 24.3. The coordinates in momentum space are $p_{x,} p_{y,} p_{z}$. The number of momentum states available to a particle with a momentum whose magnitude is between $p$ and $p+d p$ is proportional to the volume of a spherical shell in momentum space of radius $p$ and thickness $d p$.

Since

$$
\begin{equation*}
p^{2}=2 m \varepsilon \text { and } d p=\frac{m d \varepsilon}{\sqrt{2 m \varepsilon}} \tag{24.15}
\end{equation*}
$$

Eq. (24.14) becomes

$$
\begin{equation*}
g(\varepsilon) d \varepsilon=2 m^{3 / 2} B \sqrt{\varepsilon} d \varepsilon \tag{24.16}
\end{equation*}
$$

The number of molecules with energies between $\varepsilon$ and $d \varepsilon$ is therefore,

$$
\begin{equation*}
n(\varepsilon) d \varepsilon=C \sqrt{\varepsilon} e^{-\varepsilon / k T} d \varepsilon \tag{24.17}
\end{equation*}
$$

where $C\left(=2 m^{3 / 2} A B\right)$ is a constant to be evaluated. To find $C$ we make use of the normalization condition that the total number of molecules is $N$, so that

$$
\begin{equation*}
N=\int_{0}^{\infty} n(\varepsilon) d \varepsilon=C \int_{0}^{\infty} \sqrt{\varepsilon} e^{-\varepsilon / k T} d \varepsilon \tag{24.18}
\end{equation*}
$$

From integral \# 670 of Lide [10] we find that

$$
\begin{equation*}
\int_{0}^{\infty} \sqrt{x} e^{-a x} d x=\frac{1}{2 a} \sqrt{\frac{\pi}{a}} \tag{24.19}
\end{equation*}
$$

where $a=1 / k T$, such that

$$
\begin{align*}
& N=\frac{C}{2} \sqrt{\pi}(k T)^{3 / 2} \\
& C=\frac{2 \pi N}{(\pi k T)^{3 / 2}} \tag{24.20}
\end{align*}
$$

Substitution of Eq. (24.20) into Eq. (24.17) gives:

$$
\begin{equation*}
n(\varepsilon) d \varepsilon=\frac{2 \pi N}{(\pi k T)^{3 / 2}} \sqrt{\varepsilon} e^{-\varepsilon / k T} d \varepsilon \tag{24.21}
\end{equation*}
$$

Eq. (24.21) gives the number of molecules with energies between $\varepsilon$ and $\varepsilon+d \varepsilon$ in a sample of an ideal gas that contains $N$ molecules at absolute temperature $T$.

Figure 24.4. Maxwell-Boltzmann energy distribution for the molecules of an ideal gas.

The curve of Equation (24.21) plotted in terms of $k T$ (Figure 24.4) is not symmetrical about the most probable energy. This is because $\varepsilon=0$ is the lower limit to $\varepsilon$ while the upper limit is $\varepsilon \rightarrow \infty$; although, the probability of particles with energies many times greater than $k T$ is small.

The total internal energy of the system is calculated by integrating the product of $n(\varepsilon) d \varepsilon$ and the energy $\varepsilon$ over all energies from 0 to $\infty$ :

$$
\begin{equation*}
E=\int_{0}^{\infty} \varepsilon n(\varepsilon) d \varepsilon=\frac{2 \pi N}{(\pi k T)^{3 / 2}} \int_{0}^{\infty} \varepsilon^{3 / 2} e^{-\varepsilon / k T} d \varepsilon \tag{24.22}
\end{equation*}
$$

Using integral \#521 and \#670 of Lide [11]:

$$
\begin{equation*}
\int_{0}^{\infty} x^{3 / 2} e^{-a x} d x=\frac{3}{4 a^{2}} \sqrt{\frac{\pi}{a}} \tag{24.23}
\end{equation*}
$$

gives

$$
\begin{equation*}
E=\frac{2 \pi N}{(\pi k T)^{3 / 2}}\left(\frac{3}{4}\right)(k T)^{2} \sqrt{\pi k T}=\frac{3}{2} N k T \tag{24.24}
\end{equation*}
$$

This is the correct result based on the ideal-gas law's dependence on the average molecular kinetic energy being $\frac{3}{2} k T$. Eq. (24.24) confirms that the $1 / k T$ factor in the exponent of the Maxwell-Boltzmann distribution function of Eq. (24.3) properly describes the dependence of $n(\varepsilon) d \varepsilon$ on $T$. Also, from Eq. (24.24), the average energy of an ideal-gas molecule is $\frac{E}{N}$, or

$$
\begin{equation*}
\bar{\varepsilon}=\frac{3}{2} k T \tag{24.25}
\end{equation*}
$$

which is independent of the molecule's mass; however, a light molecule has a greater average speed at a given temperature than a heavy one. The value of $\bar{\varepsilon}$ at room temperature is about 0.04 eV .

A gas molecule can be excited to translate in three directions such that is possesses energy in three translational modes or degrees of freedom corresponding to motions in the $x, y$, and $z$ directions. $\frac{1}{2} k T$ of energy can be associated with each degree of freedom. This association turns out to be a quite general one; the average energy per degree of freedom of any Newtonian entity modeled by Maxwell-Boltzmann statistics that is part of a system of such entities in thermal equilibrium at the temperature $T$ is $\frac{1}{2} k T$.

For example, a harmonic oscillator has two degrees of freedom, one corresponding to its kinetic energy and the other to its potential energy. Each oscillator of a system of harmonic oscillators thus has an average energy of (2) ( $\left.\frac{1}{2}\right) k T=k T$. To a first approximation, the atoms of a solid behave like a system of Newtonian harmonic oscillators, as shown in the Application of Bose-Einstein Statistics to Model Specific Heats of Solids section.

The distribution of molecular speeds can be found from Eq. (24.21) by making the substitution

$$
\begin{align*}
& \varepsilon=\frac{1}{2} m v^{2}  \tag{24.26}\\
& d \varepsilon=m v d v
\end{align*}
$$

First obtained by Maxwell in 1859, the result for the number of molecules with speeds between $v$ and $v+d v$ is:

$$
\begin{equation*}
n(v) d v=\frac{\sqrt{2} \pi N m^{3 / 2}}{(\pi k T)^{3 / 2}} v^{2} e^{-m v^{2} / 2 k T} d v \tag{24.27}
\end{equation*}
$$

Eq. (24.27) is plotted in Figure 24.5.
Figure 24.5. Maxwell-Boltzmann speed distribution.

$v_{r m s}$, the square root of the average of the squared molecular speed of a molecule with an average energy of $\frac{3}{2} k T$ is

$$
\begin{equation*}
v_{r m s}=\sqrt{\overline{v^{2}}}=\sqrt{\frac{3 k T}{m}} \tag{24.28}
\end{equation*}
$$

since $\overline{\frac{1}{2} m v^{2}}=\frac{3}{2} k T$. This speed is denoted the root-mean-square speed which is not the same as the simple arithmetic average speed $\bar{v}$. The relationship between $\bar{v}$ and $v_{r m s}$ depends on the distribution law that governs the molecular speeds in a particular system. For a Maxwell-Boltzmann distribution,

$$
\begin{equation*}
v_{r m s}=\sqrt{\frac{3 \pi}{8}} \bar{v} \approx 1.09 \bar{v} \tag{24.29}
\end{equation*}
$$

so that the rms speed is about 9 percent greater than the arithmetical average speed. Due to the asymmetry of the speed distribution given by Eq. (24.27), the most probable speed $v_{p}$ is smaller than either $\bar{v}$ or $v_{r m s}$. To find $v_{p}$, the derivative of $n(v)$ with respect to $v$ is set equal to zero and the resulting equation is solved for $v$ :

$$
\begin{equation*}
v_{p}=\sqrt{\frac{2 k T}{m}} \tag{24.30}
\end{equation*}
$$

Molecular speeds in a gas may vary considerably about $v_{p}$ as shown (Figure 24.6) by the distributions of speeds in oxygen at $73 \mathrm{~K}\left(-200^{\circ} \mathrm{C}\right)$, in oxygen at $273 \mathrm{~K}\left(0^{\circ} \mathrm{C}\right)$, and in hydrogen at 273 K . The most probable speed increases with temperature and decreases with molecular mass such that molecular speeds in oxygen at 73 K are in totality less than at 273 K . Furthermore, the average molecular energy is the same in both oxygen and hydrogen at 273 K , but the molecular speeds in hydrogen at 273 K are in totality greater than those in oxygen at the same temperature.

Figure 24.6. The distributions of molecular speeds in oxygen at 73 K , in oxygen at 273 K , and in hydrogen at 273 K .

## APPLICATION OF BOSE-EINSTEIN STATISTICS TO MODEL BLACKBODY RADIATION

Every substance emits electromagnetic radiation with a spectrum that depends on the nature and temperature of the substance. The discrete electronic-excited-state spectra of isolated atoms of gases such as hydrogen and helium are given in the Excited States of the One-Electron Atom (Quantization) and the Excited States of Helium sections. At the other extreme, continuum spectra are observed from dense bodies such as solids. As expected, the ability of a body to radiate is closely related to its ability to absorb radiation, since a body at a constant temperature is in thermal equilibrium with its surroundings and must absorb energy from them at the same rate as it emits energy. It is convenient to consider a blackbody as an ideal body that absorbs all radiation incident upon it, independent of frequency.

Figure 24.7. Two pairs of Identical Surfaces in Thermal Equilibrium. Surfaces I and I' are identical to each other and are different from the identical pair of surfaces II and II'.

An experiment, illustrated in Figure 24.7, to demonstrate that a blackbody is the best emitter of radiation involves two identical pairs (I, I' and II, II') of dissimilar surfaces with no temperature difference observed between two of the surfaces I' and II'. At a given temperature, the surfaces I and I' radiate at the rate of $e_{1}$ while the dissimilar surfaces II and II' radiate at the different rate $e_{2}$. The surfaces I and I' absorb some fraction $a_{1}$ of the incident radiation, while the dissimilar surfaces II and II' absorb some other fraction $a_{2}$. Hence I' absorbs energy from II at a rate proportional to $a_{2} e_{1}$, and II' absorbs energy from I at a rate proportional to $a_{2} e_{1}$. For I' and II' to remain at the same temperature,

$$
\begin{equation*}
a_{1} e_{2}=a_{2} e_{1} \text { and } \frac{e_{1}}{a_{1}}=\frac{e_{2}}{a_{2}} \tag{24.31}
\end{equation*}
$$

Eq. (24.31) shows that the ability of a body to emit radiation is proportional to its ability to absorb radiation.
Next, consider that I and I' are blackbodies such that $a_{1}=1$, and II and II' are not with $a_{2}<1$. Eq. (24.31) becomes:

$$
\begin{equation*}
e_{1}=\frac{e_{2}}{a_{2}} \tag{24.32}
\end{equation*}
$$

Since $a_{2}<1$, Eq. (24.32) gives:

$$
\begin{equation*}
e_{1}>e_{2} \tag{24.33}
\end{equation*}
$$

A blackbody at a given temperature is the most effective radiator of energy.
In the analysis of thermal radiation, the concept of an idealized blackbody permits the precise nature of whatever is radiating to be disregarded, since all blackbodies behave identically. A laboratory blackbody can be approximated by a hollow object with a very small hole leading to its interior as shown in Figure 24.8. Any radiation striking the hole enters the cavity, where it is trapped by reflecting from the walls until it is absorbed. The cavity walls are constantly emitting and absorbing radiation, and the properties of this radiation (blackbody radiation) can be modeled using Einstein-Bose statistics.

Figure 24.8. A hole in the wall of a hollow object is an excellent approximation of a blackbody.

Blackbody radiation can be experimentally sampled by recording the spectrum of the light emitted from the hole in the cavity, and the results agree with our everyday experience. Blackbody radiation increases with temperature, and the spectrum of a hot blackbody has its peak at a higher frequency than the peak of the spectrum of a cooler one. For example, as an iron bar is heated to progressively higher temperature, it first glows dull red, then bright orange-red, and eventually becomes "white hot." The spectrum of blackbody radiation for two temperatures is shown in Figure 24.9.

## PLANCK RADIATION LAW

As shown in the Excited States of the One-Electron Atom (Quantization) and the Excited States of Helium sections, each bound electron is a resonator cavity, which traps single photons of discrete frequencies. Thus, photon absorption occurs as an excitation of a resonator mode. The angular momentum of the free space photon given by $\mathbf{m}=\int \frac{1}{8 \pi c} \operatorname{Re}\left[\mathbf{r} \times\left(\mathbf{E} \times \mathbf{B}^{*}\right)\right] d x^{4}=\hbar$ in the Photon section is conserved [9] for the solutions for the resonant photons and excited state electron functions. The change in angular frequency of the electron is equal to the angular frequency of the resonant photon that excites the resonator cavity mode corresponding to the transition, and the energy is given by Planck's equation. The equation of the blackbody spectrum shown in Figure 24.9 is derived using the quantization of electromagnetic radiation.

Figure 24.9. Blackbody spectra. The spectral distribution of energy in the radiation depends only on the temperature of the body.

The superposition of photons gives rise to electromagnetic waves that obey the macro Maxwell's equations. The radiation inside a cavity of temperature $T$ whose walls are perfect reflectors exists a series of three-dimensional standing electromagnetic waves.

The condition for standing waves in such a cavity is that the path length from wall to wall in any $x, y$, or $z$ direction must be an integral number $j$ of half-wavelengths such that a node occurs at each reflecting surface.

$$
\begin{align*}
& j_{x}=\frac{2 L}{\lambda}=1,2,3 \ldots=\text { number of half-wavelengths in } x \text { direction } \\
& j_{y}=\frac{2 L}{\lambda}=1,2,3 \ldots=\text { number of half-wavelengths in } y \text { direction }  \tag{24.34}\\
& j_{z}=\frac{2 L}{\lambda}=1,2,3 \ldots=\text { number of half-wavelengths in } z \text { direction }
\end{align*}
$$

Combining the components for a standing wave in any arbitrary direction gives:

$$
j_{x}^{2}+j_{y}^{2}+j_{z}^{2}=\left(\frac{2 L^{2}}{\lambda}\right) \quad \begin{align*}
& j_{x}=0,1,2, \ldots  \tag{24.35}\\
& j_{y}=0,1,2, \ldots \\
& j_{z}=0,1,2, \ldots
\end{align*}
$$

in order that the wave terminate in a node at its ends.
The number of standing waves $g(\lambda) d \lambda$ within the cavity whose wavelengths lie between $\lambda$ and $\lambda+d \lambda$ can be counted as the number of permissible sets of $j_{x}, j_{y}, j_{z}$ values that yield wavelengths in this interval. Consider a three-dimensional $j$ space whose coordinate axes are $j_{x}, j_{y}$, and $j_{z}$ where Figure 24.10 shows part of the $j_{x}-j_{y}$ plane of such a space. Each point in the $j$-space corresponds to a standing wave having a permissible set of $j_{x}, j_{y}, j_{z}$ values. The magnitude of each vector $j$ defined from the origin to a particular point $j_{x}, j_{y}, j_{z}$ is:

$$
\begin{equation*}
j=\sqrt{j_{x}^{2}+j_{y}^{2}+j_{z}^{2}} \tag{24.36}
\end{equation*}
$$

The total number of wavelengths between $\lambda$ and $\lambda+d \lambda$ is equivalent to the number of points in $j$ space whose distances from the origin lie between $j$ and $j+d j$, the volume of a spherical shell of radius $j$ and thickness $d j$ is $4 \pi j^{2} d j$. Taking the octant of this shell having positive values of $j_{x}, j_{y}$, and $j_{z}$ as physical and considering the two perpendicular directions of polarization of each standing electromagnetic wave, the number of independent standing waves in the cavity is:

$$
\begin{equation*}
g(j) d j=(2)\left(\frac{1}{8}\right)\left(4 \pi j^{2} d j\right)=\pi j^{2} d j \tag{24.37}
\end{equation*}
$$

Figure 24.10. Each point in $j$ space corresponds to a possible standing electromagnetic wave.

The number of standing waves in the cavity as a function $j$ is converted into their frequency ( $v$ ) dependence. From Eqs. (24.35) and (24.36):

$$
\begin{align*}
& j=\frac{2 L}{\lambda}=\frac{2 L v}{c}  \tag{24.38}\\
& d j=\frac{2 L}{c} d v \tag{24.39}
\end{align*}
$$

Substitution of Eqs. (24.38) and ((24.39) into Eq. (24.37) gives:

$$
\begin{equation*}
g(v) d v=\pi\left(\frac{2 L v}{c}\right)^{2} \frac{2 L}{c} d v=\frac{8 \pi L^{3}}{c^{3}} v^{2} d v \tag{24.40}
\end{equation*}
$$

The cavity volume is $L^{3}$; thus, from Eq. (24.40), the number of independent standing waves per unit volume is:

$$
\begin{equation*}
G(v) d v=\frac{1}{L^{3}} g(v) d v=\frac{8 \pi v^{2} d v}{c^{3}} \tag{24.41}
\end{equation*}
$$

To determine the average energy per standing wave, Bose-Einstein statistics are used. The energy of each photon of frequency $v$ is quantized in units of $h v$. The average number of photons $f(v)$ in each state of energy $\varepsilon=h v$ is given by the Bose-Einstein distribution function of Eq. (24.4). The value of $\alpha$ in Eq. (24.4) depends on the number of particles in the system being considered, but unlike gas molecules or electrons, photons of different frequencies (energies) are continuously emitted and absorbed. Although the total radiant energy in the cavity must remain constant, the number of free photons having this total energy can change. Because of the way in which $\alpha$ is defined in the derivation of Eq. (24.4) as given by Beiser [8], the nonconservation of the total number of photons means that $\alpha=0$ such that the Bose-Einstein distribution function for photons is

$$
\begin{equation*}
f(v)=\frac{1}{e^{\ln / k T}-1} \tag{24.42}
\end{equation*}
$$

Equation (24.41) for the number of standing waves of frequency $v$ per unit volume in a cavity is valid for the number of quantum states of frequency $v$ since photons each have two possible directions of polarization, right-hand and left-hand circular polarization. Thus, the energy density of photons in a cavity is:

$$
\begin{align*}
& u(v) d v=h v G(v) f(v) d v  \tag{24.43}\\
= & \frac{8 \pi h}{c^{3}} \frac{v^{3} d v}{e^{h y / k T}-1} \tag{24.44}
\end{align*}
$$

Equation (24.44) is the Planck radiation formula for the spectral energy density of blackbody radiation, which agrees with experimental spectra such as those of Figure 24.9.

An object need not be so hot that it glows conspicuously in the visible region in order to be radiating. Every body of condensed matter radiates according to Eq. (24.44), regardless of its temperature. For example, an object at room temperature radiates predominantly in the infrared part of the spectrum, which are nonvisible frequencies.

Wien's displacement law and the Stefan-Boltzmann law can be obtained from the Planck radiation formula. The wavelength whose energy density is the greatest is obtained by expressing Eq. (24.44) in terms of wavelength and solving $d u(\lambda) d \lambda=0$ for $\lambda=\lambda_{\text {max }}$ :

$$
\begin{equation*}
\frac{h c}{k T \lambda_{\max }}=4.965 \tag{24.45}
\end{equation*}
$$

Eq. (24.45) can be more conveniently expressed as:

$$
\begin{equation*}
\lambda_{\max } T=\frac{h c}{4.965 k}=2.898 \times 10^{-3} \mathrm{~m} \cdot \mathrm{~K} \tag{24.46}
\end{equation*}
$$

Equation (24.46) known as Wien's displacement law quantitatively expresses the observation that the peak in the blackbody spectrum shifts to progressively shorter wavelengths (higher frequencies) as the temperature is increased as shown in Figure 24.9.

The total energy density $u$ within the cavity we can also be obtained from Eq. (24.44) by integrating the energy density over all frequencies:

$$
\begin{equation*}
u=\int_{0}^{\infty} u(v) d v=\frac{8 \pi^{5} k^{4}}{15 c^{3} h^{3}} T^{4}=a T^{4} \tag{24.47}
\end{equation*}
$$

where $a$ is a universal constant. The total energy density is proportional to the fourth power of the absolute temperature of the cavity walls. Similarly, the energy $R$ radiated by an object per second per unit area is also proportional to $T^{4}$. This result is shown by the Stefan-Boltzmann law:

$$
\begin{equation*}
R=e \sigma T^{4} \tag{24.48}
\end{equation*}
$$

where Stefan's constant $\sigma$ is given by $\sigma=\frac{a c}{4}=5.670 \times 10^{-8} \mathrm{~W} / \mathrm{m}^{2} \cdot K^{4}$.
The emissivity $e$ depends on the nature of the radiating surface and ranges from 0 , for a perfect reflector with zero radiation, to 1 , for a blackbody. Some exemplary values of $e$ are 0.07 for polished steel, 0.06 for oxidized copper and brass, and 0.97 for matte black paint.

## APPLICATION OF BOSE-EINSTEIN STATISTICS TO MODEL SPECIFIC HEATS OF SOLIDS

Consider, $C_{V}$, the molar specific heat of a solid at constant volume which is the energy that must be added to 1 kmole of the substance at fixed volume to raise its temperature by $1 \mathrm{~K} . C_{P}$, the specific heat at constant pressure, is 3 to 5 percent higher than $C_{V}$ in solids because it includes the work associated with a volume change as well as the change in internal energy. The internal energy of a solid resides in the vibrations of its constituent particles, which may be atoms, ions, or molecules. These vibrations may be resolved into components along three perpendicular axes, such that each particle (designated as an atom for convenience) can be represented by three harmonic oscillators. Using Bose-Einstein statistics, the probability $f(v)$ that an oscillator has the frequency $v$ is given by Eq. (24.42), $f(v)=1 /\left(e^{h y / k T}-1\right)$. Hence, the average energy for an oscillator whose frequency of vibration is $v$ is:

$$
\begin{equation*}
\bar{\varepsilon}=h v f(v)=\frac{h v}{e^{h / / k T}-1} \tag{24.49}
\end{equation*}
$$

Therefore, the total internal energy of a kilomole of a solid is given by:

$$
\begin{equation*}
E=3 N_{0} \bar{\varepsilon}=\frac{3 N_{0} h v}{e^{h / k T}-1} \tag{24.50}
\end{equation*}
$$

and its molar specific heat is:

$$
\begin{equation*}
C_{V}=\left(\frac{\partial E}{\partial T}\right)_{V}=3 R\left(\frac{h v}{k T}\right)^{2} \frac{e^{h \nu / k T}}{\left(e^{h v / k T}-1\right)^{2}} \tag{24.51}
\end{equation*}
$$

Thus, at high temperatures $h v \ll k T$, and

$$
\begin{equation*}
e^{h v / k T} \approx 1+\frac{h v}{k T} \tag{24.52}
\end{equation*}
$$

since

$$
\begin{equation*}
e^{x}=1+x+\frac{x^{2}}{2!}+\frac{x^{3}}{3!}+\ldots \tag{24.53}
\end{equation*}
$$

Hence Eq. (24.49) becomes:

$$
\begin{equation*}
\bar{\varepsilon} \approx h v /(h v / k T)=k T \tag{24.54}
\end{equation*}
$$

which leads to $C_{V} \approx 3 R$. At high temperatures the spacing $h \nu$ between possible energies is small relative to $k T$, so $\varepsilon$ is effectively continuous and Maxwell-Boltzmann statistics applies.

As the temperature decreases, the value of $C_{V}$ given by Eq. (24.51) decreases. The deviation from Maxwell Boltzmann behavior arises as the spacing between possible energies becomes large relative to $k T$. The natural frequency $v$ for a particular solid can be determined by comparing Eq. (24.51) with an empirical curve of $C_{V}$ versus $T$. The result in the case of aluminum is $v=6.4 \times 10^{12} \mathrm{~Hz}$, which agrees with estimates made in other ways, for instance on the basis of elastic moduli [5].

Eq. (24.51) predicts that $C_{V} \rightarrow 0$ as $T \rightarrow 0$ in agreement with observations. However, better models to the actual behavior of $C_{V}$ as $T \rightarrow 0$ such as Debye's [5] take into account that a solid is a continuous elastic body wherein the internal energy of a solid resides in elastic standing waves, rather than vibrations of individual atoms. The elastic waves in a solid are of two kinds, longitudinal and transverse, and range in frequency from 0 to a maximum $v_{m}$. (The interatomic spacing in a solid sets a lower limit to the possible wavelengths and hence an upper limit to the frequencies.) Typically, the total number of different standing waves in a mole of a solid is equal to its $3 N_{A}$ degrees of freedom. These waves, like electromagnetic waves, have energies quantized in units of $h v$. A quantum of acoustic energy in a solid is called a phonon, and it travels with the speed of sound since sound waves are elastic in nature. The concept of phonons is quite general and has applications other than in connection with specific heats. A phonon gas has the same statistical behavior as a photon gas or a system of harmonic oscillators in thermal equilibrium, so that the average energy $\bar{\varepsilon}$ per standing wave is the same as in Eq. (24.49). The resulting formula for $C_{V}$, which is fairly complicated, reproduces the curves of $C_{V}$ versus $T$ quite well at all temperatures.

## APPLICATION OF FERMI-DIRAC STATISTICS TO MODEL FREE ELECTRONS IN A METAL

Fermi-Dirac statistics corresponds to the physics of electrons wherein no more than one electron can occupy each quantum state. Although systems of bosons and fermions both approach Maxwell-Boltzmann statistics with average energies $\bar{\varepsilon}=\frac{1}{2} k T$ per degree of freedom at "high" temperatures, in a metal, the transition temperature range for Maxwell-Boltzmann behavior is not necessarily the same for the two kinds of systems. According to Eq. (24.7), the distribution function that gives the average occupancy of a quantum state of energy $\varepsilon$ in a system of fermions is

$$
\begin{equation*}
f_{F D}(\varepsilon)=\frac{1}{e^{\left(\varepsilon-\varepsilon_{F}\right) / k T}+1} \tag{24.55}
\end{equation*}
$$

An expression for $g(\varepsilon) d \varepsilon$, the number of quantum states available to electrons with energies between $\varepsilon$ and $\varepsilon+d \varepsilon$, is obtained using the same approach as that to used to determine the number of standing waves in a cavity with the wavelength $\lambda$ in the Planck Radiation Law section. The correspondence is exact because there are two possible spin states, $m_{s}=+\frac{1}{2}$ and $m_{s}=-\frac{1}{2}$ ("up" and "down"), for electrons, just as there are two independent directions of polarization for otherwise identical standing waves.

Using Eq. (24.37), the number of standing waves in a cubical cavity $L$ on a side is:

$$
\begin{equation*}
g(j) d j=\pi j^{2} d j \tag{24.56}
\end{equation*}
$$

where $j=2 L / \lambda$. In the case of an electron, $\lambda$ is its de Broglie wavelength of $\lambda=\frac{h}{p}$. Electrons in a metal have nonrelativistic velocities, so $p=\sqrt{2 m_{e} \varepsilon}$ and

$$
\begin{align*}
& j=\frac{2 L}{\lambda}=\frac{2 L p}{h}=\frac{2 L \sqrt{2 m_{e} \varepsilon}}{h}  \tag{24.57}\\
& d j=\frac{L}{h} \sqrt{\frac{2 m_{e}}{\varepsilon}} d \varepsilon
\end{align*}
$$

Using these expressions for $j$ and $d j$ in Eq. (24.37) gives:

$$
\begin{equation*}
g(\varepsilon) d \varepsilon=\frac{8 \sqrt{2} \pi L^{3} m_{e}^{3 / 2}}{h^{3}} \sqrt{\varepsilon} d \varepsilon \tag{24.58}
\end{equation*}
$$

As in the case of standing waves in a cavity the exact shape of the metal sample does not matter; so, its volume $V$ can substituted for $L^{3}$ to give:

$$
\begin{equation*}
g(\varepsilon) d \varepsilon=\frac{8 \sqrt{2} \pi V m_{e}^{3 / 2}}{h^{3}} \sqrt{\varepsilon} d \varepsilon \tag{24.59}
\end{equation*}
$$

Using Eq. (24.59), the Fermi energy $\varepsilon_{F}$ can be calculated by filling up the energy states in the metal sample with the $N$ free electrons it contains in order of increasing energy starting from $\varepsilon=0$ such that the highest state to be filled has the energy $\varepsilon=\varepsilon_{F}$. This is the definition of $\varepsilon_{F}$ as given in the Three Different Kinds of Atomic-Scale Statistical Distributions section. The number of electrons that can have the same energy $\varepsilon$ is equal to the number of states that have this energy, since each state is: limited to one electron.

$$
\begin{equation*}
N=\int_{0}^{\varepsilon_{F}} g(\varepsilon) d \varepsilon=\frac{8 \sqrt{2} \pi V m_{e}^{3 / 2}}{h^{3}} \int_{0}^{\varepsilon_{F}} \sqrt{\varepsilon} d \varepsilon=\frac{16 \sqrt{2} \pi V m_{e}^{3 / 2}}{3 h^{3}} \varepsilon_{F}^{3 / 2} \tag{24.60}
\end{equation*}
$$

and

$$
\begin{equation*}
\varepsilon_{F}=\frac{h^{2}}{2 m_{e}}\left(\frac{3 N}{8 \pi V}\right)^{2 / 3}=\frac{h^{2}}{2 m_{e}}\left(\frac{3}{8 \pi}\right)^{2 / 3} n^{2 / 3} \tag{24.61}
\end{equation*}
$$

The quantity $\frac{N}{V}$ is the density of free electrons.

## ELECTRON-ENERGY DISTRIBUTION

Using Eqs. (24.7) and (24.59), the number of electrons in an electron gas that have energies between $\varepsilon$ and $\varepsilon+d \varepsilon$ is

$$
\begin{equation*}
n(\varepsilon) d \varepsilon=g(\varepsilon) f(\varepsilon) d \varepsilon=\frac{\left(\frac{8 \sqrt{2} \pi V m_{e}^{3 / 2}}{h^{3}}\right) \sqrt{\varepsilon} d \varepsilon}{e^{\left(\varepsilon-\varepsilon_{F}\right) / R T}+1} \tag{24.62}
\end{equation*}
$$

Expressing the numerator of Eq. (24.62) in terms of the Fermi energy $\varepsilon_{F}$ (Eq. (24.61)) gives :

$$
\begin{equation*}
n(\varepsilon) d \varepsilon=\frac{\left(\frac{3 N}{2}\right) \varepsilon_{F}^{-3 / 2} \sqrt{\varepsilon} d \varepsilon}{e^{\left(\varepsilon-\varepsilon_{F}\right) / k T}+1} \tag{24.63}
\end{equation*}
$$

Eq. (24.63) is plotted in Figure 24.11 for $T=0,300$, and 1200 K .

Figure 24.11. Distribution of electron energies in a metal at various temperatures.

To determine the average electron energy at 0 K , the total energy $E_{0}$ at 0 K is first obtained by the following integral:

$$
\begin{equation*}
E_{0}=\int_{0}^{\varepsilon_{F}} \varepsilon n(\varepsilon) d \varepsilon \tag{24.64}
\end{equation*}
$$

Since at $T=0 \mathrm{~K}$, all of the electrons have energies less than or equal to the Fermi energy $\varepsilon_{F}$, the temperature-dependent term becomes:

$$
\begin{equation*}
e^{\left(\delta-\varepsilon_{F}\right) / k T}=e^{-\infty}=0 \tag{24.65}
\end{equation*}
$$

and Eqs. (24.63) and (24.64) gives:

$$
\begin{equation*}
E_{0}=\frac{3 N}{2} \varepsilon_{F}^{-3 / 2} \int_{0}^{\varepsilon_{F}} \varepsilon^{3 / 2} d \varepsilon=\frac{3}{5} N \varepsilon_{F} \tag{24.66}
\end{equation*}
$$

The average electron energy $\bar{\varepsilon}_{0}$ is this total energy divided by the number of electrons present $N$, which gives:

$$
\begin{equation*}
\bar{\varepsilon}_{0}=\frac{3}{5} \varepsilon_{F} \tag{24.67}
\end{equation*}
$$

Since Fermi energies for metals are usually several eVs (Table 24.2), the average electron energy in them at 0 K will also be of this order of magnitude. In contrast, the temperature of an ideal gas whose molecules have an average kinetic energy of 1 eV is $11,600 \mathrm{~K}$.

Table 24.2. Some Fermi energies.

| Metal |  | Fermi energy, eV |
| :--- | :--- | :---: |
| Lithium | Li | 4.72 |
| Sodium | Na | 3.12 |
| Aluminum | Al | 11.8 |
| Potassium | K | 2.14 |
| Cesium | Cs | 1.53 |
| Copper | Cu | 7.04 |
| Zinc | Zn | 11.0 |
| Silver | Ag | 5.51 |
| Gold | Au | 5.54 |

The failure of the free electrons in a metal to contribute appreciably to its specific heat is due to the behavior of the electron energy distribution. When a metal is heated, only those electrons with thermal energy near the very top of the energy distribution-those within about $k T$ of the Fermi energy-are excited to the higher energy states while the less energetic electrons cannot absorb more energy because the states above them are already filled. An electron with a low energy $\varepsilon$ in the range of 0.5 eV below $\varepsilon_{F}$ is unlikely to undergo a transition to the nearest vacant state above the intervening states that are already filled since $k T$ at room temperature is 0.025 eV and even at 500 K it is only 0.043 eV .

A detailed calculation shows that the specific heat of the electron gas in a metal is given by [5] :

$$
\begin{equation*}
C_{V e}=\frac{\pi^{2}}{2}\left(\frac{k T}{\varepsilon_{F}}\right) R \tag{24.68}
\end{equation*}
$$

For the metals listed in Table 24.2, $\frac{k T}{\varepsilon_{F}}$ at room temperature ranges from 0.016 for cesium to 0.0021 for aluminum; so, the coefficient of $R$ is very much smaller than the Maxwell Boltzmann figure of $\frac{3}{2}$. The atomic specific heat $C_{V}$ in a metal is much greater than the electronic specific heat over a wide temperature range. However, at very low temperatures $C_{V e}$ becomes significant because $C_{V}$ is then approximately proportional to $T^{3}$ whereas $C_{V e}$ is proportional to $T$. At very high temperatures, $C_{V}$ approaches the value of about $3 R$ while $C_{V e}$ continues to increase such that the contribution of $C_{V e}$ to the total specific heat is detectable.

## Chapter 25

## SUPERCONDUCTIVITY

In the case of a superconductor, an applied voltage gives rise to a transient constant electric field in the $z$ direction

$$
\begin{align*}
& \mathbf{E}_{z}=E_{0} \cos \theta \mathbf{i}_{z}  \tag{25.1}\\
& \mathbf{E}_{z}=E_{0} \mathbf{i}_{z} \tag{25.2}
\end{align*}
$$

where $\mathbf{i}_{z}$ is the unit vector along the z-axis.
The applied field polarizes the material into a superconducting current comprised of current dipoles, i.e. magnetic dipoles. In Cartesian coordinates, the magnetic field, $\mathbf{H}$, at the point $(x, y, z)$ due to a magnetic dipole having a magnetic dipole moment of a Bohr magneton, $\mu_{B}$, at the position $\left(x_{0}, y_{0}, z_{0}\right)$ is:

$$
\begin{align*}
& \mathbf{H}=\frac{\mu_{B}\left(2\left(z-z_{0}\right)^{2}-\left(x-x_{0}\right)^{2}-\left(y-y_{0}\right)^{2}\right)}{\left[\left(x-x_{0}\right)^{2}+\left(y-y_{0}\right)^{2}+\left(z-z_{0}\right)^{2}\right]^{5 / 2}} \mathbf{i}_{z}  \tag{25.3}\\
& \mathbf{H}=\frac{\left(2 z^{2}-x^{2}-y^{2}\right)}{\left[x^{2}+y^{2}+z^{2}\right]^{5 / 2}} \otimes \mu_{B} \delta\left(x-x_{0}, y-y_{0}, z-z_{0}\right) \mathbf{i}_{z} \tag{25.4}
\end{align*}
$$

The field is the convolution of the system function, $h(x, y, z)$ or $h(\rho, \phi, z)$, (the left-handed part of Eq. (25.4)) with the delta function (the right-hand part of Eq. (25.4)) at the position $\left(x_{0}, y_{0}, z_{0}\right)$. A very important theorem of Fourier analysis states that the Fourier transform of a convolution is the product of the individual Fourier transforms [1]. The Fourier transform of the system function, $h(x, y, z)$ or $h(\rho, \phi, z)$, is given in Box 25.1.

## BOX 25.1 FOURIER TRANSFORM OF THE SYSTEM FUNCTION

The system function, $h(\rho, \phi, z)$, in cylindrical coordinates is

$$
\begin{equation*}
h(\rho, \phi, z)=\frac{2 z^{2}-x^{2}-y^{2}}{\left[x^{2}+y^{2}+z^{2}\right]^{5 / 2}}=\frac{2 z^{2}-\rho^{2}}{\left[\rho^{2}+z^{2}\right]^{5 / 2}} \tag{1}
\end{equation*}
$$

The spacetime Fourier transform in three dimensions in cylindrical coordinates, $H\left(k_{\rho}, \Phi, k_{z}\right)$, is given [1] as follows:

$$
\begin{equation*}
H\left(k_{\rho}, \Phi, k_{z}\right)=\int_{-\infty}^{\infty} \int_{0}^{2 \pi} \int_{0}^{\infty} h(\rho, \phi, z) \exp \left(-i 2 \pi\left[k_{\rho} \rho \cos (\Phi-\phi)+k_{z} z\right]\right) \rho d \rho d \phi d z \tag{2}
\end{equation*}
$$

With circular symmetry [1]:

$$
\begin{equation*}
H\left(k_{\rho}, k_{z}\right)=2 \pi \int_{0}^{\infty} \int_{-\infty}^{\infty} h(\rho, z) J_{0}\left(k_{\rho} \rho\right) e^{-i w z} \rho d \rho d z \tag{3}
\end{equation*}
$$

The Fourier transform of the system function is given by the substitution of Eq. (1) into Eq. (3).

$$
\begin{equation*}
H=\int_{-\infty}^{\infty} 2 \pi \int_{0}^{\infty} \frac{2 z^{2}-\rho^{2}}{\left[\rho^{2}+z^{2}\right]^{5 / 2}} J_{0}\left[k_{\rho} \rho\right] \rho d \rho e^{-j k_{z} z} d z \tag{4}
\end{equation*}
$$

Consider the integral of Eq. (4) with respect to $d \rho$ only. Factorization of $h(\rho, \phi, z)$ gives:

$$
\begin{equation*}
2 \pi \int_{0}^{\infty}\left[\frac{2 z^{2} \rho}{\left[\rho^{2}+z^{2}\right]^{5 / 2}}-\frac{\rho^{3}}{\left[\rho^{2}+z^{2}\right]^{5 / 2}}\right] J_{0}\left[k_{\rho} \rho\right] d \rho \tag{5}
\end{equation*}
$$

Consider the definite integral

$$
\begin{equation*}
\int_{0}^{\infty} \frac{t^{v+1} J_{v}[a t] d t}{\left[t^{2}+z^{2}\right]^{u+1}}=\frac{a^{u} z^{v-u} K_{v-u}[a z]}{2^{u} \Gamma[u+1]} \tag{6}
\end{equation*}
$$

and the relationship between modified Bessel functions of the third kind where:

$$
\begin{equation*}
K_{-v}[x]=K_{\nu}[x] \tag{7}
\end{equation*}
$$

The first factor of Eq. (5) is the same form as Eq. (6) with $v=0 ; u=\frac{3}{2}$, thus,

$$
\begin{equation*}
2 z^{2}(2 \pi) \int_{0}^{\infty} \frac{\rho}{\left[\rho^{2}+z^{2}\right]^{5 / 2}} J_{0}\left[k_{\rho} \rho\right] d \rho=\frac{2 z^{2}(2 \pi) k_{\rho}^{3 / 2} z^{-3 / 2}}{2^{3 / 2} \Gamma[5 / 2]} K_{-3 / 2}\left[k_{\rho} z\right]=\frac{\left[2^{1 / 2}\right] \pi z^{1 / 2} k_{\rho}^{3 / 2}}{\Gamma[5 / 2]} K_{3 / 2}\left[k_{\rho} z\right] \tag{8}
\end{equation*}
$$

where $K_{-3 / 2}\left[k_{\rho} z\right]=K_{3 / 2}\left[k_{\rho} z\right]$ (Eq. (7)). The second factor of Eq. (5) can be made into the same form as Eq. (6) using the recurrence relationship of Bessel functions of the first kind:

$$
\begin{equation*}
J_{v-1}[x]+J_{v+1}[x]=\frac{2 v}{x} J_{v}[x] \tag{9}
\end{equation*}
$$

Consider the second factor of the integral of Eq. (5) thus,

$$
\begin{equation*}
-2 \pi \int_{0}^{\infty} \frac{\rho^{3}}{\left[\rho^{2}+z^{2}\right]} J_{0}\left[k_{p} \rho\right] d \rho \tag{10}
\end{equation*}
$$

Eq. (9) with $v=1$ is:

$$
\begin{align*}
& J_{0}[x]+J_{2}[x]=\frac{2}{x} J_{1}[x]  \tag{11}\\
& J_{0}[x]=\frac{2}{x} J_{1}[x]-J_{2}[x] \tag{12}
\end{align*}
$$

Let

$$
\begin{equation*}
x=k_{\rho} \rho \tag{13}
\end{equation*}
$$

Substitution of Eq. (13) into Eq. (12) is:

$$
\begin{equation*}
J_{0}\left[k_{\rho} \rho\right]=\frac{2}{k_{\rho} \rho} J_{1}\left[k_{\rho} \rho\right]-J_{2}\left[k_{\rho} \rho\right] \tag{14}
\end{equation*}
$$

Substitution of Eq. (10) into Eq. (14) is:

$$
\begin{align*}
-2 \pi \int_{0}^{\infty} \frac{\rho^{3}}{\left[\rho^{2}+z^{2}\right]} J_{0}\left[k_{\rho} \rho\right] d \rho & =-2 \pi \int_{0}^{\infty} \frac{\rho^{3}}{\left[\rho^{2}+z^{2}\right]^{5 / 2}}\left[\frac{2}{k_{\rho} \rho} J_{1}\left[k_{\rho} \rho\right]-J_{2}\left[k_{\rho} \rho\right]\right] d \rho  \tag{15}\\
& =-2 \pi \int_{0}^{\infty} \frac{2 \rho^{2}}{k_{\rho}\left[\rho^{2}+z^{2}\right]^{5 / 2}} J_{1}\left[k_{\rho} \rho\right] d \rho+2 \pi \int_{0}^{\infty} \frac{\rho^{3}}{\left[\rho^{2}+z^{2}\right]^{5 / 2}} J_{2}\left[k_{\rho} \rho\right] d \rho
\end{align*}
$$

The first factor of the right hand side of Eq. (15) is the same form as Eq. (6) with $v=1 ; u=\frac{3}{2}$, thus,

$$
\begin{equation*}
-2 \pi \int_{0}^{\infty} \frac{2 \rho^{2}}{k_{\rho}\left[\rho^{2}+z^{2}\right]^{5 / 2}} J_{1}\left[k_{\rho} \rho\right] d \rho=\frac{-(4 \pi) k_{\rho}^{3 / 2} z^{-1 / 2}}{k_{\rho} 2^{3 / 2} \Gamma[5 / 2]} K_{-1 / 2}\left[k_{\rho} z\right]=-\frac{\left[2^{1 / 2}\right] \pi z^{-1 / 2} k_{\rho}^{1 / 2}}{\Gamma[5 / 2]} K_{1 / 2}\left[k_{\rho} z\right] \tag{16}
\end{equation*}
$$

where $K_{-1 / 2}\left[k_{\rho} z\right]=K_{1 / 2}\left[k_{\rho} z\right]$ (Eq. (7)). The second factor of the right hand side of Eq. (15) is the same form as Eq. (6) with $v=2 ; u=\frac{3}{2}$, thus,

$$
\begin{equation*}
2 \pi \int_{0}^{\infty} \frac{\rho^{3}}{\left[\rho^{2}+z^{2}\right]^{5 / 2}} J_{2}\left[k_{\rho} \rho\right] d \rho=\frac{(2 \pi) k_{\rho}^{3 / 2} z^{1 / 2}}{2^{3 / 2} \Gamma[5 / 2]} K_{1 / 2}\left[k_{\rho} z\right]=\frac{\pi z^{1 / 2} k_{\rho}^{3 / 2}}{\left[2^{1 / 2}\right] \Gamma[5 / 2]} K_{1 / 2}\left[k_{\rho} z\right] \tag{17}
\end{equation*}
$$

Combining the parts of the integration with respect to $d \rho$ of Eq. (4) by adding Eq. (8), Eq. (16), and Eq. (17) gives:

$$
\begin{equation*}
\int_{-\infty}^{\infty}\left[\frac{\left[2^{1 / 2}\right] \pi z^{1 / 2} k_{\rho}^{1 / 2}}{\Gamma[5 / 2]} K_{3 / 2}\left[k_{\rho} z\right]-\frac{\left[2^{1 / 2}\right] \pi z^{1 / 2} k_{\rho}^{1 / 2}}{\Gamma[5 / 2]} K_{1 / 2}\left[k_{\rho} z\right]+\frac{\pi z^{1 / 2} k_{\rho}^{3 / 2}}{\left[2^{1 / 2}\right] \Gamma[5 / 2]} K_{1 / 2}\left[k_{\rho} z\right]\right] e^{-j k_{z} z} d z \tag{18}
\end{equation*}
$$

The modified Bessel functions of the third kind may be expressed as:

$$
\begin{equation*}
K_{n+1 / 2}[x]=\left[\frac{\pi}{2 x}\right]^{1 / 2} e^{-x} \sum_{m=0}^{n}[2 x]^{-m} \frac{\Gamma[n+m+1]}{m!\Gamma[n+1-m]} \tag{19}
\end{equation*}
$$

Substitution of Eq. (13) into Eq. (19) with $v=1$ is:

$$
\begin{equation*}
K_{3 / 2}\left[k_{\rho} z\right]=\left[\frac{\pi}{2 k_{\rho} z}\right]^{1 / 2} e^{-k_{\rho} z}\left[1+\frac{1}{2 k_{\rho} z} \Gamma[3]\right] \tag{20}
\end{equation*}
$$

Substitution of Eq. (13) into Eq. (19) with $v=0$ is:

$$
\begin{equation*}
K_{1 / 2}\left[k_{\rho} z\right]=\left[\frac{\pi}{2 k_{\rho} z}\right]^{1 / 2} e^{-k_{\rho} z} \tag{21}
\end{equation*}
$$

Substitution of Eq. (20) and Eq. (21) into Eq. (18) is:

$$
\begin{align*}
& \int_{-\infty}^{\infty}\left\{\left[\frac{\left(2^{1 / 2}\right) \pi z^{1 / 2} k_{\rho}^{3 / 2}}{\Gamma[5 / 2]}\left[1+\frac{1}{2 k_{\rho} z} \Gamma[3]\right]-\frac{\left(2^{1 / 2}\right) \pi z^{1 / 2} k_{\rho}^{1 / 2}}{\Gamma[5 / 2]}+\frac{\pi z^{1 / 2} k_{\rho}^{3 / 2}}{\left(2^{1 / 2}\right) \Gamma[5 / 2]}\right]\left[\frac{\pi}{2 k_{\rho} z}\right]^{1 / 2} e^{-k_{\rho} z}\right\} e^{-j k_{z} z} d z  \tag{22}\\
& \int_{-\infty}^{\infty}\left\{\frac{\pi^{3 / 2}}{\Gamma[5 / 2]} k_{\rho} e^{-\left[j k_{z}+k_{\rho}\right] z}+\frac{z^{-1} \pi^{3 / 2} \Gamma[3]}{\Gamma[5 / 2] 2} e^{-\left[j k_{z}+k_{\rho}\right] z}-\frac{z^{-1} \pi^{3 / 2}}{\Gamma[5 / 2]} e^{-\left[j k_{z}+k_{\rho}\right] z}+\frac{\pi^{3 / 2}}{\Gamma[5 / 2] 2} k_{\rho} e^{-\left[j k_{z}+k_{\rho}\right] z}\right\} d z \tag{23}
\end{align*}
$$

Collecting terms gives:

$$
\begin{equation*}
\int_{-\infty}^{\infty} \frac{\pi^{3 / 2}}{\Gamma[5 / 2]}\left\{k_{\rho}[1+1 / 2]+\left[\frac{\Gamma[3]}{2}-1\right] z^{-1}\right\} e^{-\left[j k_{z}+k_{\rho}\right] z} d z \tag{24}
\end{equation*}
$$

With $\Gamma[3]=2$ and $\Gamma[5 / 2]=3 / 4 \pi^{1 / 2}$, Eq. (24) is:

$$
\begin{align*}
& \int_{-\infty}^{\infty} \frac{\pi^{3 / 2}}{\Gamma[5 / 2]}\left\{k_{\rho}[3 / 2]+[1-1] z^{-1}\right\} e^{-k_{\rho} z} e^{-j k_{z} z} d z  \tag{25}\\
& \int_{-\infty}^{\infty} \frac{\pi^{3 / 2}}{3 / 4 \pi^{1 / 2}} 3 / 2 k_{\rho} e^{-k_{\rho} z} e^{-j k_{z} z} d z  \tag{26}\\
& 2 \pi k_{\rho} \int_{-\infty}^{\infty} e^{-k_{\rho} z} e^{-j k_{z} z} d z  \tag{27}\\
& 4 \pi k_{\rho} \int_{0}^{\infty} e^{-k_{\rho} z} e^{-j k_{z} z} d z  \tag{28}\\
& 4 \pi k_{\rho} \int_{0}^{\infty} e^{-\left[j k_{z}+k_{\rho}\right] z} d z \tag{29}
\end{align*}
$$

Integration of Eq. (29) with respect to $d z$ gives:

$$
\begin{align*}
& 4 \pi k_{\rho}\left\{\left.\frac{-1}{j k_{z}+k_{\rho}} e^{-\left[j k_{z}+k_{\rho}\right] z}\right|_{0} ^{\infty}\right\}  \tag{30}\\
& 4 \pi k_{\rho}\left[\frac{1}{j k_{z}+k_{\rho}}\right] \tag{31}
\end{align*}
$$

Multiplication of Eq. (31) by:

$$
\begin{equation*}
1=\left[\frac{-j k_{z}+k_{\rho}}{-j k_{z}+k_{\rho}}\right] \tag{32}
\end{equation*}
$$

gives:

$$
\begin{equation*}
4 \pi k_{\rho}\left[\frac{-j k_{z}+k_{\rho}}{k_{z}^{2}+k_{\rho}{ }^{2}}\right] \tag{33}
\end{equation*}
$$

The system function (Eq. (1)) is an even function; thus, the spacetime Fourier transform in three dimensions in cylindrical coordinates, $H\left(k_{\rho}, k_{z}\right)$, is given by taking the real part of Eq. (33) [2]:

$$
\begin{equation*}
H\left[k_{\rho}, k_{z}\right]=\frac{4 \pi k_{\rho}{ }^{2}}{k_{z}^{2}+k_{\rho}{ }^{2}} \tag{34}
\end{equation*}
$$

The spacetime Fourier transform in three dimensions in Cartesian coordinates, $H\left(k_{\rho}, k_{z}\right)$, is:

$$
\begin{equation*}
H\left[k_{x}, k_{y}, k_{z}\right]=\frac{4 \pi\left[k_{x}^{2}+k_{y}^{2}\right]}{\left[k_{x}^{2}+k_{y}^{2}+k_{z}^{2}\right]} \tag{35}
\end{equation*}
$$

where the relationship between the wave numbers and the spatial Cartesian coordinates is as follows:

$$
\begin{align*}
& k_{x}=\frac{2 \pi}{\lambda_{x}}=\frac{1}{x}  \tag{36}\\
& k_{y}=\frac{2 \pi}{\lambda_{y}}=\frac{1}{y} \tag{37}
\end{align*}
$$

$$
\begin{equation*}
k_{z}=\frac{2 \pi}{\lambda_{z}}=\frac{1}{z} \tag{38}
\end{equation*}
$$

## BAND-PASS FILTER

The z component of a magnetic dipole oriented in the z direction has the system function, $h(x, y, z)$, which has the Fourier transform, $H\left[k_{x}, k_{y}, k_{z}\right]$, which is shown in Figure 25.1.

$$
\begin{align*}
H\left[k_{x}, k_{y}, k_{z}\right] & =\frac{4 \pi\left[k_{x}{ }^{2}+k_{y}^{2}\right]}{\left[k_{x}{ }^{2}+k_{y}{ }^{2}+k_{z}{ }^{2}\right]}  \tag{25.5}\\
& =H\left[k_{\rho}, k_{z}\right]=\frac{4 \pi k_{\rho}{ }^{2}}{k_{z}{ }^{2}+k_{\rho}{ }^{2}}=\frac{4 \pi}{1+\frac{k_{z}{ }^{2}}{k_{\rho}{ }^{2}}} \tag{25.6}
\end{align*}
$$

Figure 25.1. The Fourier transform $H\left[k_{x}, k_{y}, k_{z}\right]$ of the system function $h(x, y, z)$ corresponding to the z component of a magnetic dipole oriented in the z direction.

As shown in the Electron Scattering by Helium section, in the far field, the amplitude of the scattered electromagnetic radiation or scattered electron flux density is the Fourier transform of the aperture function. In the case of a superconductor, the electric field is zero-no voltage drop occurs; however, a magnetic field is present. The relationship between the amplitude of the scattered energy and the Fourier transform of the aperture function can be applied to the present case of the scattering of magnetic energy by the lattice of the potential superconductor. The spatial aperture function is the convolution of the array pattern with the elemental pattern. The elemental pattern is the system function, $h(x, y, z)$, which is the geometric transfer function for the z component of a z oriented magnetic dipole. And, the array pattern is a periodic array of delta functions each at the position of a magnetic dipole corresponding to a current carrying electron.

$$
\begin{equation*}
\frac{\left(2 z^{2}-x^{2}-y^{2}\right)}{\left[x^{2}+y^{2}+z^{2}\right]^{5 / 2}} \otimes \sum_{n=-\infty}^{\infty} \mu_{B} \delta\left(x-n x_{0}, y-n y_{0}, z-n z_{0}\right) \tag{25.7}
\end{equation*}
$$

The Fourier transform of a periodic array of delta functions (the right-hand side of Eq. (25.7)) is also a periodic array of delta functions in k-space:

$$
\begin{equation*}
\frac{1}{x_{0} y_{0} z_{0}} \sum_{n=-\infty}^{\infty} \mu_{B} \delta\left(k_{x}-\frac{n}{x_{0}}, k_{y}-\frac{n}{y_{0}}, k_{z}-\frac{n}{z_{0}}\right) \tag{25.8}
\end{equation*}
$$

By the Fourier Theorem, the Fourier transform of the spatial aperture function, Eq. (25.7), is the product of the Fourier transform of the elemental function, system function given by Eq. (25.6), and the Fourier transform of the array function given by Eq. (25.8):

$$
\begin{equation*}
\frac{4 \pi}{1+\frac{k_{z}^{2}}{k_{\rho}^{2}}} \frac{1}{x_{0} y_{0} z_{0}} \sum_{n=-\infty}^{\infty} \mu_{B} \delta\left(k_{x}-\frac{n}{x_{0}}, k_{y}-\frac{n}{y_{0}}, k_{z}-\frac{n}{z_{0}}\right) \tag{25.9}
\end{equation*}
$$

The spacetime aperture function corresponding to the current-density function is given by multiplying the spatial aperture function (Eq. (25.7)) by a time harmonic function

$$
\begin{equation*}
\exp (-i \omega t) \tag{25.10}
\end{equation*}
$$

Thus, the spacetime aperture function is:

$$
\begin{equation*}
\frac{\left(2 z^{2}-x^{2}-y^{2}\right)}{\left[x^{2}+y^{2}+z^{2}\right]^{5 / 2}} \otimes \sum_{n=-\infty}^{\infty} \mu_{B} \delta\left(x-n x_{0}, y-n y_{0}, z-n z_{0}\right) \exp (-i \omega t) \tag{25.11}
\end{equation*}
$$

The Fourier transform of the time harmonic function (Eq. (25.10)) is:

$$
\begin{equation*}
\frac{\left[\delta\left(\omega-\omega_{z}\right)+\delta\left(\omega-\omega_{z}\right)\right]}{2} \tag{25.12}
\end{equation*}
$$

A very important theorem of Fourier analysis states that the Fourier transform of a product is the convolution of the individual Fourier transforms. Thus, the Fourier transform of Eq. (25.11) is the convolution of Eqs. (25.9) and (25.12) :

$$
\begin{equation*}
\frac{4 \pi}{1+\frac{k_{z}^{2}}{k_{\rho}^{2}}} \frac{1}{x_{0} y_{0} z_{0}} \sum_{n=-\infty}^{\infty} \mu_{B} \delta\left(k_{x}-\frac{n}{x_{0}}, k_{y}-\frac{n}{y_{0}}, k_{z}-\frac{n}{z_{0}}\right) \otimes \frac{\left[\delta\left(\omega-\omega_{z}\right)+\delta\left(\omega-\omega_{z}\right)\right]}{2} \tag{25.13}
\end{equation*}
$$

In the special case that:

$$
\begin{equation*}
k_{\rho}=k_{z} \tag{25.14}
\end{equation*}
$$

the Fourier transform of the system function (the left-hand side of Eq. (25.13)) is given by:

$$
\begin{equation*}
H=4 \pi \tag{25.15}
\end{equation*}
$$

Thus, the Fourier transform of the system function band-passes the Fourier transform of the time dependent array function. Both the spacetime aperture function, Eq. (25.11) and its Fourier transform, Eq. (25.13), are a periodic array of delta functions. No frequencies of the Fourier transform of the spacetime aperture function are attenuated; thus, no energy is lost in this special case where Eq. (25.14) holds. (This result is also central to a powerful new medical imaging technology-4 Dimensional Magnetic Resonance Imaging (4D-MRI [2]). No energy loss corresponds to a superconducting state. And the relationship between kspace and real space is:

$$
\begin{align*}
& k_{x}=\frac{2 \pi}{\lambda_{x}}=\frac{1}{x} \\
& k_{y}=\frac{2 \pi}{\lambda_{y}}=\frac{1}{y}  \tag{25.16}\\
& k_{z}=\frac{2 \pi}{\lambda_{z}}=\frac{1}{z}
\end{align*}
$$

From Eqs. (25.14) and (25.16), it follows that a cubic array ( $x_{0}=y_{0}=z_{0}$ ) of magnetic dipoles centered on the nuclei of the lattice is a superconductor when the temperature is less than the critical temperature such that the superconducting electrons can propagate. Propagating electrons that carry the superconducting current and comprise magnetic dipoles form standing waves centered on the nuclear centers of the cubic lattice. Fermi-Dirac statistics apply to electrons as given in the Statistical Mechanics section. It follows from Eqs. (25.14) and (25.16) that the Fermi energy is calculated for a cubical cavity $L$ on a side. The number standing waves in a cubical cavity L on a side is given by Eq. (9.33) of Beiser [3] :

$$
\begin{equation*}
g(j) d j=\pi j^{2} d j \tag{25.17}
\end{equation*}
$$

where

$$
\begin{equation*}
j=\frac{2 L}{\lambda} \tag{25.18}
\end{equation*}
$$

The de Broglie wavelength of an electron is:

$$
\begin{equation*}
\lambda=\frac{h}{p} \tag{25.19}
\end{equation*}
$$

Electrons in superconductors have non relativistic velocities; so,

$$
\begin{equation*}
p=\sqrt{2 m_{e} \varepsilon} \tag{25.20}
\end{equation*}
$$

where $\varepsilon$ is the kinetic energy and

$$
\begin{align*}
& j=\frac{2 L}{\lambda}=\frac{2 L p}{h}=\frac{2 L \sqrt{2 m_{e} \varepsilon}}{h}  \tag{25.21}\\
& d j=\frac{L}{h} \sqrt{\frac{2 m_{e}}{\varepsilon}} d \varepsilon \tag{25.22}
\end{align*}
$$

Using these expressions for $j$ and $d j$ in Eq. (25.17) gives:

$$
\begin{equation*}
g(\varepsilon) d \varepsilon=\frac{8 \sqrt{2} \pi L^{3} m_{e}^{3 / 2}}{h^{3}} \sqrt{\varepsilon} d \varepsilon \tag{25.23}
\end{equation*}
$$

Substitution of $V$ for $L^{3}$ gives the number of electron states, $g(\varepsilon)$

$$
\begin{equation*}
g(\varepsilon) d \varepsilon=\frac{8 \sqrt{2} \pi V m_{e}^{3 / 2}}{h^{3}} \sqrt{\varepsilon} d \varepsilon \tag{25.24}
\end{equation*}
$$

The Fermi energy, $E_{F}$, is calculated by equating the number of free electrons, $N$, to the integral over the electron states of energy $\varepsilon$ from zero to the highest energy, the Fermi energy, $E=E_{F}$.

$$
\begin{align*}
N & =\int_{0}^{E_{F}} g(\varepsilon) d \varepsilon=\frac{8 \sqrt{2} \pi V m_{e}^{3 / 2}}{h^{3}} \int_{0}^{E_{F}} \sqrt{\varepsilon} d \varepsilon  \tag{25.25}\\
& =\frac{16 \sqrt{2} \pi V m_{e}^{3 / 2}}{3 h^{3}} E_{F}^{3 / 2} \tag{25.26}
\end{align*}
$$

and the Fermi energy is:

$$
\begin{equation*}
E_{F}=\frac{h^{2}}{2 m_{e}}\left(\frac{3 N}{8 \pi V}\right)^{2 / 3}=\frac{h^{2}}{2 m_{e}}\left(\frac{3}{8 \pi}\right)^{2 / 3} n^{2 / 3} \tag{25.27}
\end{equation*}
$$

The quantity $N / V=n$ is the density of free electrons.
In the case of superconducting electrons, comprising an array of magnetic dipoles (each dipole in the xy-plane and oriented along the z-axis), the dimensions of Eq. (9.33) of Beiser [3] is reduced to 2 from 3.

$$
\begin{equation*}
2 \frac{1}{4} 2 \pi j=g(j) \tag{25.28}
\end{equation*}
$$

For $g(j)=1$ with the substitution of Eq. (25.18),

$$
\begin{equation*}
2 \pi L=\lambda \tag{25.29}
\end{equation*}
$$

As the temperature of a superconducting material rises from a temperature below the critical temperature, $T_{c}$, the number density, $n_{s}$, of superconducting electrons decreases. At the transition temperature, the superconducting electrons condense into a nondissipative electron current ensemble, which obeys the statistics of a Bose gas (each electron is identical and indistinguishable as indicated in Eq. (25.8) with the constraint of Eq. (25.14)), and Eqs. (25.28) and (25.29) apply:

$$
\begin{equation*}
\left(\frac{2 \pi}{\lambda}\right)^{3}=\left(\frac{1}{L}\right)^{3}=n_{s} \tag{25.30}
\end{equation*}
$$

where

$$
\begin{equation*}
n_{s} E_{F}=n k_{B} T_{c} \tag{25.31}
\end{equation*}
$$

$n_{s}$ is the number density of superconducting electrons within $k_{B} T_{c}$ of the Fermi energy and $n$ is the number density of free electrons. The current carried by each superconducting electron corresponds to a translational or kinetic energy. The relationship between the electron de Broglie wavelength (Eqs. (25.19) and (25.20)) and the average electron energy, $\bar{\varepsilon}$, per degree of freedom, $f$, given by Beiser [4]:

$$
\begin{equation*}
\bar{\varepsilon}=\frac{f}{2} k_{B} T_{c}=\Delta \quad f=3,2, \text { or } 1 \tag{25.32}
\end{equation*}
$$

is

$$
\begin{equation*}
\lambda=\frac{h}{\left(2 m_{e}\left(\frac{1}{2} f k_{B} T_{c}\right)\right)^{1 / 2}}=\frac{h}{\left(m_{e} f k_{B} T_{c}\right)^{1 / 2}} \tag{25.33}
\end{equation*}
$$

where in the present case of an inverse squared central field, the binding energy or energy gap of the superconducting state, $\Delta$, is one half the negative of the potential energy and equal to the kinetic energy [5]. Consider the case wherein the Fermi energy is that of a three dimensional system, but the motion of superconducting electrons is restricted to 3 , 2 , or 1 directions corresponding to $f=3,2$, or 1 , respectively. Combining Eqs. (25.30-25.33) gives the transition temperature,

$$
\begin{equation*}
T_{c}=\frac{8}{(2 \pi)^{6}}\left(\frac{8 \pi}{3}\right)^{2} \frac{E_{F}}{k_{B} f^{3}} \tag{25.34}
\end{equation*}
$$

where the Fermi energy, $E_{F}$, is given by Eq. (25.27). An isotope effect can be manifested indirectly by changing the rms. position of atoms which effects the condition of Eq. (25.14) or the Fermi energy by changing the bond and vibrational energies. The superconducting electrons are equivalent to those of metals and semiconductors in the conduction state given in the Nature
of the Metallic Bond of Alkali Metals section and the Nature of the Semiconductor Bond of Silicon section, respectively. The electron supercurrents confined to two-dimensions corresponding to $f=2$ in Eq. (25.32) are shown pictorially in Figures $25.2 \mathrm{~A}-25.2 \mathrm{~F}$. Except for their distribution in the lattice, the individual electron planes of superconductors are the same as those of metals. This aspect has been experimentally confirmed by using high-intensity pulsed magnetic fields that cause the superconducting electrons to behave the same as those in metals [6].

Figure 25.2A-F. A superconductor comprising covalent bonds and metallic (free) electrons showing the superconducting current as two-dimensional membranes of zero thickness that are each an equipotential energy surface comprised of the superposition of multiple electrons. The membranes called bands carry the current along two axes in the plane. Such a band is shown separately in (B).

## CRITICAL TEMPERATURE, T $_{c}$

## $\mathbf{T}_{\mathbf{c}}$ FOR CONVENTIONAL THREE DIMENSIONAL METALLIC SUPERCONDUCTORS

In the case of conventional three dimensional metallic superconductors, the number density of conduction electrons is comparable to the number density of atoms-approximately $10^{29} / \mathrm{m}^{3}$. Thus, the calculated transition temperature (Eq. (25.34)) is
$T_{c}=30.8 \mathrm{~K}$
As a comparison, the material of this class with the highest known transition of $23.2 K$ is $\mathrm{Nb}_{3} \mathrm{Ge}$ [7].

## Tc FOR ONE, TWO, OR THREE DIMENSIONAL CERAMIC OXIDE SUPERCONDUCTORS <br> In the case of ceramic oxide superconductors, one, two, and three dimensional conduction mechanisms are possible. The

 number density of conduction electrons is less than that of metallic superconductors-approximately $10^{28} / \mathrm{m}^{3}$. For the threedimensional case, the calculated transition temperature (Eq. (25.34)) is:$$
T_{c}=7 \mathrm{~K}
$$

As a comparison, a possible material of this class, $\mathrm{Li}_{2} \mathrm{TiO}_{3}$ has a transition temperature of 13.7 K [8].
For the two-dimensional case,
$T_{c}=22 \mathrm{~K}$
As a comparison, a possible material of this class, the original Bednorz and Muller $\mathrm{Ba}-\mathrm{La}-\mathrm{Cu}-\mathrm{O}$ material has a transition temperature of $35 K$ [7].

For the one-dimensional case,
$T_{c}=180 \mathrm{~K}$
As a comparison, a possible material of this class, $T l-C a-B a-C u-O$ has a transition temperature of $120-125 K$ [9]. The existence of superconductivity confined to stripes has been observed experimentally by neutron scattering [10].

Transition temperatures which are intermediate of each of these limiting cases are possible where combinations of conduction mechanism are present.

## JOSEPHSON JUNCTION, WEAK LINK

As shown in the Electron $g$ Factor section, the electron links flux in units of the magnetic flux quantum. Thus, the magnetic flux that links a superconducting loop with a weak link is the magnetic flux quantum, $\Phi_{0}$.

$$
\begin{equation*}
\Phi_{0}=\frac{h}{2 e} \tag{25.35}
\end{equation*}
$$

The factor of $2 e$ in the denominator has been erroneously interpreted [11] as evidence that Cooper pairs are the superconducting current carriers, which is central to the BCS theory of superconductors. This theory fails to explain so called High Temperature Superconductors. These materials have a transition temperature, which corresponds to an internal electron energy that is well above the energy limits at which the BCS theory permits conduction electron pairing. According to CP , Cooper pairs do not exist, and CP is consistent with the existence of High Temperature Superconductors as well as the experimental result that the magnetic flux that links a superconducting loop with a weak link is the magnetic flux quantum, $\Phi_{0}$. Cooper pairs are also disproved by the existence of a spin triplet supercurrent [12].

## Chapter 26

## QUANTUM HALL EFFECT

## GENERAL CONSIDERATIONS

When confined to two dimensions and subjected to a magnetic field, electrons exhibit a range of extraordinary behavior, most notably the Quantum Hall Effect (QHE). Two distinct versions of this phenomenon are observed, the Integral Quantum Hall Effect (IQHE) and the Fractional Quantum Hall Effect (FQHE). The former involves the condition for re-establishment of a superconducting state of one well in the presence of a magnetic field; whereas, the latter involves the condition for reestablishment of a superconducting state of two magnetically linked wells in the presence of a magnetic field.

Consider a conductor in a uniform magnetic field and assume that it carries a current driven by an electric field perpendicular to the magnetic field. The current in this case is not parallel to the electric field, but is deflected at an angle to it by the magnetic field. This is the Hall Effect, and it occurs in most conductors.

In the Quantum Hall Effect, the applied magnetic field quantizes the Hall conductance. The current is then precisely perpendicular to the magnetic field, so that no dissipation (that is no ohmic loss) occurs. This is seen in two-dimensional systems, at cryogenic temperatures, in quite high magnetic fields. Furthermore, the ratio of the total electric potential drop to the total current, the Hall resistance, $R_{H}$, is precisely equal to:

$$
\begin{equation*}
R_{H}=\frac{h}{n e^{2}}=\frac{25812.807 \Omega}{n} \tag{26.1}
\end{equation*}
$$

The factor $n$ is an integer in the case of the Integral Quantum Hall Effect, and $n$ is a small rational fraction in the case of the Fractional Quantum Hall Effect. In an experimental plot [1] as the function of the magnetic field, the Hall resistance exhibits flat steps precisely at these quantized resistance values; whereas, the regular resistance vanishes (or is very small) at these Hall steps. Thus, the quantized Hall resistance steps occur for a transverse superconducting state.

As shown in the Superconductivity section, superconductivity arises for an array of current carrying magnetic dipoles when:

$$
\begin{equation*}
k_{p}=k_{z} \tag{26.2}
\end{equation*}
$$

Thus, the Fourier transform of the system function band-passes the Fourier transform of the time dependent array function. Both the spacetime aperture function and its Fourier transform are a periodic array of delta functions. No frequencies of the Fourier transform of the spacetime aperture function are attenuated; thus, no energy is lost in this special case where Eq. (26.2) holds. Consider the case that an external magnetic field is applied along the x -axis to a two-dimensional superconductor in the yzplane, which exhibits the Integral Quantum Hall Effect. (See Figure 26.1.) The magnetic field is expelled from the bulk of the superconductor by the supercurrent (Meissner Effect). The supercurrent-density function is a minimum energy surface; thus, the magnetic flux decays exponentially at the surface as given by the London Equation [2]. The Meissner current increases as a function of the applied flux. The energy of the superconducting electrons increases with flux. This energy increase is equivalent to lowering the critical temperature in Eq. (25.31) of the Superconductivity section which is given by:

$$
\begin{equation*}
n_{s} E_{F}=n k T_{c} \tag{26.3}
\end{equation*}
$$

where $n_{s}$ is the number density of superconducting electrons within $k T_{c}$ of the Fermi energy and $n$ is the number density of free electrons. At the critical current, the material loses superconductivity and becomes normal at a temperature below that of the critical temperature in the absence of an applied field. Conduction electrons align with the applied field in the x direction as the field permeates the material. The normal current carrying electrons experience a Lorentz force, $\mathbf{F}_{L}$, due to the magnetic flux. The y directed Lorentz force on an electron having a velocity $\mathbf{v}$ in the z direction by an x directed applied flux, $\mathbf{B}$, is

$$
\begin{equation*}
\mathbf{F}_{L}=e \mathbf{v} \times \mathbf{B} \tag{26.4}
\end{equation*}
$$

The electron motion is a cycloid where the center of mass experiences an $\mathbf{E} \times \mathbf{B}$ drift [3]. Consequently, the normal Hall Effect occurs. Conduction electron energy states are altered by the applied field and by the electric field corresponding to the Hall Effect. The electric force, $\mathbf{F}_{H}$, due to the Hall electric field, $\mathbf{E}_{y}$, is:

$$
\begin{equation*}
\mathbf{F}_{L}=e \mathbf{E}_{y} \tag{26.5}
\end{equation*}
$$

When these two forces are equal and opposite, conduction electrons propagate in the z direction alone. For this special case, it is demonstrated in Jackson [3] that the ratio of the corresponding Hall electric field and the applied magnetic flux is:

$$
\begin{equation*}
E / B=v \tag{26.6}
\end{equation*}
$$

where $\mathbf{v}$ is the electron velocity. At a temperature below $T_{c}$, given by Eq. (26.3) where $E_{F}$ is the Fermi energy, Eq. (26.6) is satisfied. The further conditions for superconductivity are:

$$
\begin{align*}
& n \omega_{\rho}=\omega_{z}  \tag{26.7}\\
& n k_{\rho}=k_{z} \tag{26.8}
\end{align*}
$$

And, it is demonstrated in the Integral Quantum Hall Effect section that the Hall resistance, $R_{H}$, in the superconducting state is given by:

$$
\begin{equation*}
R_{H}=\frac{h}{n e^{2}} \tag{26.9}
\end{equation*}
$$

where $n$ of Eqs. (26.7), (26.8), and (26.9) is the same integer for the case of a single superconducting well. It is demonstrated in the Fractional Quantum Hall Effect section that electrons in different superconducting wells can interact when the two wells are separated by a distance comparable to the magnetic length, $\ell_{0}$ :

$$
\begin{equation*}
\ell_{0}=\left(\frac{\hbar c}{e B}\right)^{1 / 2} \tag{26.10}
\end{equation*}
$$

In this case, it is further demonstrated that the Hall resistance, $R_{H}$, in the superconductivity state is given by Eq. (26.9) where $n$ is a fraction.

## INTEGRAL QUANTUM HALL EFFECT

A superconducting current-density function is nonradiative and does not dissipate energy as was the case for single electron current-density functions described previously in the One-Electron Atom section, the Two Electron Atom section, the Three Electron Atom section, the Electron in Free Space section, and the Nature of the Chemical Bond section. Furthermore, a superconducting current-density function is the superposition of single electron current-density functions which are spatially two dimensional in nature. Thus, a superconducting current-density function is an electric and magnetic equipotential energy surface. The nature of electrons in materials as such extended surfaces is observed by scanning tunneling electron microscopy (STM) [4].

From Eq. (1.36), the angular frequency in spherical coordinates which satisfies the boundary condition for nonradiation is:

$$
\begin{equation*}
\omega=\frac{\hbar}{m_{e} r^{2}}=\frac{(2 \pi)^{2} \hbar}{m_{e}(2 \pi r)^{2}} \tag{26.11}
\end{equation*}
$$

The relationship between the electron wavelength and the radius, which satisfies the nonradiative boundary condition in spherical coordinates is given by Eq. (1.15):

$$
\begin{equation*}
2 \pi r=\lambda \tag{26.12}
\end{equation*}
$$

Substitution of Eq. (26.12) into Eq. (26.11) gives:

$$
\begin{equation*}
\omega=\frac{\hbar}{m_{e}} k^{2} \tag{26.13}
\end{equation*}
$$

where

$$
\begin{equation*}
k=\frac{2 \pi}{\lambda} \tag{26.14}
\end{equation*}
$$

It follows from Eq. (1.35) where:

$$
\begin{equation*}
v=\frac{\hbar}{m_{e} r}=\frac{\hbar}{m_{e}} k \tag{26.15}
\end{equation*}
$$

In a solid lattice, the coordinates are Cartesian rather than spherical. The relationship between the wavelength of a standing wave of a superconducting electron and the length, $x$, of a cubical unit cell follows from Eqs. (25.28) and (25.29) of the

Superconductivity section

$$
\begin{equation*}
\lambda=2 \pi r \tag{26.16}
\end{equation*}
$$

The de Broglie wavelength, $\lambda$ is given by:

$$
\begin{equation*}
\lambda=\frac{h}{m_{e} v} \tag{26.17}
\end{equation*}
$$

It follows from Eqs. (26.14), (26.16), and (26.17) that the angular velocity, $\omega$, and linear velocity, $v$, for an electron held in force balance by a periodic array of nuclei comprising a cubical unit cell with internuclear spacing $x$ are given by Eqs. (26.13) and (26.15) where:

$$
\begin{equation*}
k=\frac{2 \pi}{\lambda}=\frac{1}{x} \tag{26.18}
\end{equation*}
$$

In general, the Cartesian coordinate wavenumber, $k$, given by Eq. (26.18) replaces $\frac{1}{r}$ of spherical coordinates.
In the case of an exact balance between the Lorentz force (Eq. (26.4)) and the electric force corresponding to the Hall voltage (Eq. (26.5)), each superconducting electron propagates along the z -axis where:

$$
\begin{equation*}
E / B=v \tag{26.19}
\end{equation*}
$$

where $v$ is given by Eq. (26.15). Substitution of Eqs. (26.15) and (26.18) into Eq. (26.19) gives:

$$
\begin{equation*}
E / B=\frac{\hbar}{m_{e}} k=\frac{\hbar}{m_{e} x} \tag{26.20}
\end{equation*}
$$

Eq. (26.20) is the condition for superconductivity in the presence of crossed electric and magnetic fields. The Hall resistance for this superconducting state is derived as follows using the coordinate system shown in Figure 26.1.

Figure 26.1. Coordinate system of crossed electric field, $\mathbf{E}_{y}$, corresponding to the Hall voltage, magnetic flux, $\mathbf{B}_{x}$, due to applied field, and superconducting current, $\mathbf{i}_{z}$.

The current is perpendicular to $\mathbf{E}_{y}$, thus there is no dissipation. This occurs when,

$$
\begin{equation*}
e \mathbf{E}=e \mathbf{v} \times \mathbf{B} \tag{26.21}
\end{equation*}
$$

or

$$
\begin{equation*}
E / B=v \tag{26.22}
\end{equation*}
$$

The magnetic flux, $\mathbf{B}$, is quantized in terms of the Bohr magneton because an electron, and therefore a superconductor, links flux in units of the magnetic flux quantum,

$$
\begin{equation*}
\Phi_{0}=\frac{h}{2 e} \tag{26.23}
\end{equation*}
$$

The electric field, $\mathbf{E}_{y}$, corresponding to the Hall voltage, $V_{H}$, is quantized in units of $e$ because this electric field arises from conduction electrons-each of charge $e$. The energy, $E_{H}$, corresponding to the Hall voltage is calculated using the Poynting Power Theorem. The Hall energy of an integer number of electrons, $Z$, each in the presence of a magnetic dipole and an electric field of magnitude $Z e$ due to the $Z$ electrons follows for Eqs. (7.46) and (7.63) of the Two Electron Atom section where

$$
\begin{equation*}
E_{H}=Z E_{\text {mag }}=\frac{Z \pi \mu_{0} e^{2} \hbar^{2} k^{3}}{Z m_{e}{ }^{2}} \tag{26.24}
\end{equation*}
$$

where $k$ is given by Eq. (26.13) and where the electric energy of Eq. (7.63) is zero because each electron is a conduction electron. In the limit to a superconducting state, the trajectory of each electron is a cycloid where $\omega_{p}$ is the angular frequency in the xy-plane and $\omega_{z}$ is angular the frequency along the z-axis. In this case, the dipole array function given in the Superconductivity section is multiplied by a time harmonic function with argument $\omega_{p}$

$$
\begin{equation*}
\frac{\left(2 z^{2}-x^{2}-y^{2}\right)}{\left[x^{2}+y^{2}+z^{2}\right]^{5 / 2}} \otimes \sum_{n=-\infty}^{\infty} \mu_{B} \delta\left(x-n x_{0}, y-n y_{0}, z-n z_{0}\right) \exp (-i \omega t) \tag{26.25}
\end{equation*}
$$

where

$$
\begin{equation*}
\omega=\omega_{\rho}+\omega_{z} \tag{26.26}
\end{equation*}
$$

The Fourier transform of the convolved functions of Eq. (26.25) is given in the Superconductivity section as:

$$
\begin{equation*}
\frac{4 \pi}{1+\frac{k_{z}^{2}}{k_{\rho}^{2}}} \frac{1}{x_{0} y_{0} z_{0}} \sum_{n=-\infty}^{\infty} \mu_{B} \delta\left(k_{x}-\frac{n}{x_{0}}, k_{y}-\frac{n}{y_{0}}, k_{z}-\frac{n}{z_{0}}\right) \tag{26.27}
\end{equation*}
$$

The Fourier transform of the time harmonic function is:

$$
\begin{equation*}
\frac{\left[\delta\left(\omega-\left(\omega_{p}-\omega_{z}\right)\right)+\delta\left(\omega+\left(\omega_{p}-\omega_{z}\right)\right)\right]}{2} \tag{26.28}
\end{equation*}
$$

A very important theorem of Fourier analysis states that the Fourier transform of a product is the convolution of the individual Fourier transforms. Thus, the Fourier transform of Eq. (26.25) is the convolution of Eqs. (26.27) and (26.28) where

$$
\begin{equation*}
\frac{4 \pi}{1+\frac{k_{z}^{2}}{k_{\rho}^{2}}} \frac{1}{x_{0} y_{0} z_{0}} \sum_{n=-\infty}^{\infty} \mu_{B} \delta\left(k_{x}-\frac{n}{x_{0}}, k_{y}-\frac{n}{y_{0}}, k_{z}-\frac{n}{z_{0}}\right) \otimes \frac{\left[\delta\left(\omega-\left(\omega_{p}-\omega_{z}\right)\right)+\delta\left(\omega+\left(\omega_{p}-\omega_{z}\right)\right)\right]}{2} \tag{26.29}
\end{equation*}
$$

Eq. (26.29) is a band-pass when

$$
\begin{equation*}
n k_{p}=k_{z} \tag{26.30}
\end{equation*}
$$

and when

$$
\begin{equation*}
\frac{\omega_{z}}{\omega_{\rho}}=n \tag{26.31}
\end{equation*}
$$

where $n$ is an integer. The cyclotron angular frequency, $\omega_{p}$, is derived as follows:
The force balance between the Lorentz force and the centrifugal force is:

$$
\begin{equation*}
\frac{m_{e} \mathbf{v}^{2}}{r}=e \mathbf{v} \times \mathbf{B} \tag{26.32}
\end{equation*}
$$

The magnetic flux, $\mathbf{B}$, from a magnetic moment of a Bohr magneton is:

$$
\begin{equation*}
B=\frac{\mu_{0} e \hbar}{2 m_{e}} k^{3} \tag{26.33}
\end{equation*}
$$

Cancellation of $\mathbf{v}$ on both sides of Eq. (26.32) gives:

$$
\begin{align*}
& m_{e} \omega=e \times \mathbf{B}  \tag{26.34}\\
& \omega_{\rho}=\frac{e B}{m_{e}} \tag{26.35}
\end{align*}
$$

Substitution of Eq. (26.33) into Eq. (26.35) gives:

$$
\begin{equation*}
\omega_{\rho}=\frac{\mu_{0} e^{2} \hbar}{2 m_{e}{ }^{2}} k^{3} \tag{26.36}
\end{equation*}
$$

Substitution of Eq. (26.31) into Eq. (26.36) gives:

$$
\begin{equation*}
\omega_{z}=\frac{n \mu_{0} e^{2} \hbar}{2 m_{e}{ }^{2}} k^{3} \tag{26.37}
\end{equation*}
$$

The current, $\mathbf{i}_{z}$, along the z -axis is given as the product of the charge, $e$, and $\omega_{z}$, the angular frequency along the z-axis where:

$$
\begin{equation*}
\mathbf{i}_{z}=e \omega_{z}=\frac{n \mu_{0} e^{3} \hbar}{2 m_{e}{ }^{2}} k^{3} \tag{26.38}
\end{equation*}
$$

The Hall voltage is given as the energy per coulomb:

$$
\begin{equation*}
V_{H}=\frac{E_{m a g}}{e}=\frac{\pi \mu_{0} e \hbar^{2} k^{3}}{m_{e}{ }^{2}} \tag{26.39}
\end{equation*}
$$

Thus, the Hall resistance, $R_{H}$, is given as the ratio of the Hall voltage (Eq. (26.39)) and the current, $\mathbf{i}_{z}$, (Eq. (26.38))

$$
\begin{equation*}
R_{H}=\frac{V_{H}}{i_{z}}=\frac{\frac{\pi \mu_{0} e \hbar^{2} k^{3}}{2 m_{e}{ }^{2}}}{\frac{n \mu_{0} e^{3} \hbar k^{3}}{2 m_{e}{ }^{2}}}=\frac{h}{n e^{2}} \tag{26.40}
\end{equation*}
$$

The velocity of each superconducting electron according to Eq. (26.22) is:

$$
\begin{equation*}
E / B=v \tag{26.41}
\end{equation*}
$$

which is derived as follows:
The Hall electric field, $\mathbf{E}_{y}$, is given by the ratio of the Hall voltage and the distance of the cyclotron orbit, $2 \pi x$, where the unit cell distance, $x$, wavenumber, $k$, by Eq. (26.16) where:

$$
\begin{equation*}
\mathbf{E}_{y}=V_{H} \frac{k}{2 \pi} \tag{26.42}
\end{equation*}
$$

where $V_{H}$ is given by Eq. (26.39):

$$
\begin{equation*}
\mathbf{E}_{y}=\frac{\pi \mu_{0} e \hbar^{2} k^{4}}{2 \pi m_{e}{ }^{2}} \tag{26.43}
\end{equation*}
$$

The magnetic field, $\mathbf{B}$, is given by Eq. (26.33); thus the velocity $\mathbf{v}$ is given as:

$$
\begin{equation*}
\mathbf{v}=\frac{\frac{\pi \mu_{0} e \hbar^{2} k^{4}}{2 \pi m_{e}{ }^{2}}}{\frac{\mu_{0} e \hbar k^{3}}{2 m_{e}}}=\frac{\hbar}{m_{e}} k \tag{26.44}
\end{equation*}
$$

Eq. (26.44) is equivalent to the velocity for nonradiation given by Eq. (1.35), where:

$$
\begin{equation*}
\frac{2 \pi}{2 \pi r}=\frac{2 \pi}{\lambda}=k \tag{26.45}
\end{equation*}
$$

This superconducting phenomenon whereby the Hall resistance occurs as inverse integer multiples of:

$$
\begin{equation*}
\frac{h}{e^{2}} \tag{26.46}
\end{equation*}
$$

is the Integral Quantum Hall Effect (IQHE).

## FRACTIONAL QUANTUM HALL EFFECT

For two superconducting wells separated by the magnetic length, $\ell_{0}$,

$$
\begin{equation*}
\ell_{0}=\left(\frac{\hbar c}{e B}\right)^{1 / 2}=\left(\frac{c}{\pi} \frac{\Phi_{0}}{B}\right)^{1 / 2} \tag{26.47}
\end{equation*}
$$

where $\Phi_{0}$ given by Eq. (26.23) is the magnetic flux quantum, the wells are linked. Electrons can propagate from one well to the other with activation energy where:

$$
\begin{equation*}
\left|\frac{\Delta E_{\operatorname{mag}}}{E_{\operatorname{mag}}}\right| \propto \frac{e^{2}}{\ell_{0}} \tag{26.48}
\end{equation*}
$$

In the case that a magnetic field is applied to both well one and well two, and that an exact balance between the Lorentz force (Eq. (26.4)) and the electric force corresponding to the Hall voltage (Eq. (26.5)) exists, each superconducting electron propagates along the z -axis where

$$
\begin{align*}
& \frac{E_{1}}{B_{1}}=v_{1}  \tag{26.49}\\
& \frac{E_{2}}{B_{2}}=v_{2} \tag{26.50}
\end{align*}
$$

Because the two wells are linked,

$$
\begin{equation*}
v_{1}=j v_{2} \tag{26.51}
\end{equation*}
$$

where j is an integer. Eq. (26.51) provides that the electrons are in phase with:

$$
\begin{equation*}
\frac{2 \pi}{\lambda_{1}}=k_{1}=j \cdot k_{2}=j \frac{2 \pi}{\lambda_{2}} \tag{26.52}
\end{equation*}
$$

where the de Broglie wavelength is given by Eq. (26.19). Otherwise, $E_{z} \neq 0$, and the state is not superconducting. It follows from the derivation of Eq. (26.40) of the Integral Quantum Hall Effect section that:

$$
\begin{equation*}
\frac{E_{1}}{n_{1} B_{01}}=v_{1} \tag{26.53}
\end{equation*}
$$

and,

$$
\begin{equation*}
\frac{E_{2}}{n_{2} B_{01}}=v_{2} \tag{26.54}
\end{equation*}
$$

where $n_{1}$ and $n_{2}$ are integers. From Eqs. (26.52), (26.53), and (26.54) where:

$$
\begin{equation*}
E_{1}=j \frac{n_{1}}{n_{2}} \frac{E_{2}}{B_{01}} B_{01} \tag{26.55}
\end{equation*}
$$

The resistance of each well is proportional to the transverse velocity as shown previously, and the resistance across both linked wells which are in series is the sum of the individual resistances. Thus, the total resistance is proportional to the sum of the individual velocities.

$$
\begin{equation*}
R \propto\left(\frac{E_{1}}{n_{1} B_{01}}+\frac{E_{2}}{n_{2} B_{01}}\right) \tag{26.56}
\end{equation*}
$$

Substitution of Eq. (26.55) into Eq. (26.56) gives:

$$
\begin{equation*}
R \propto \frac{E_{2}}{B_{01}} \frac{1}{n_{2}}(j+1) \tag{26.57}
\end{equation*}
$$

It follows from the derivation of Eq. (26.40) of the Integral Quantum Hall Effect section that Hall resistance, $R_{H}$, is:

$$
\begin{equation*}
R_{H}=\frac{V_{H}}{i_{z}}=\frac{(j+1) \frac{\pi \mu_{0} e \hbar^{2} k^{3}}{m_{e}{ }^{2}}}{\frac{n_{2} \mu_{0} e^{3} \hbar k^{3}}{2 m_{e}{ }^{2}}}=\frac{h}{n e^{2}} \tag{26.58}
\end{equation*}
$$

where $n$ is a fraction. This superconducting phenomenon whereby the Hall resistance occurs as inverse fractional multiples of

$$
\begin{equation*}
\frac{h}{e^{2}} \tag{26.59}
\end{equation*}
$$

is the Fractional Quantum Hall Effect (FQHE).

## Chapter 27

## AHARONOV-BOHM EFFECT

The resistance of a circuit corresponds to the decrease in the energy of the current carrying electrons as they propagate through the circuit. Scattering of the electrons is a principal mechanism. In the case where a magnetic field is applied such that the field lines are perpendicular to the plane of a current carrying ring, the current carrying electrons lose energy through the effect of the field on the current.

The application of the magnetic field to the current carrying ring initially gives rise to a changing flux through the ring. The changing flux gives rise to an electric field that reduces the current in the ring; thus, the magnetic field contributes a term called magnetoresistance to the resistance of the ring. This term can be derived from the change in velocity (assuming no scattering) of a current carrying electron of charge, $e$, and mass, $m_{e}$, by the application of a magnetic field of strength, B, which is given as Eq. (29) of Purcell [1] :

$$
\begin{equation*}
\frac{\Delta \mathbf{v}}{r}=\frac{e \mathbf{B}}{2 m_{e}} \tag{27.1}
\end{equation*}
$$

where $r$ is the radius of the ring. The changes in the force on the electron due to the electric field is:

$$
\begin{equation*}
\Delta \mathbf{F}=e \Delta \mathbf{E} \tag{27.2}
\end{equation*}
$$

The change in kinetic energy of the electron over length, $s$, is:

$$
\begin{equation*}
\frac{1}{2} m_{e} \Delta \mathbf{v}^{2}=\Delta \mathbf{F} s=e \Delta \mathbf{E} s=e \Delta V \tag{27.3}
\end{equation*}
$$

where $\Delta V$ is the change in voltage over the distance, $s$. From Eq. (27.3), the voltage change is:

$$
\begin{equation*}
\Delta V=\frac{m_{e} \Delta v^{2}}{2 e} \tag{27.4}
\end{equation*}
$$

The change in current, $\Delta \mathbf{i}$, per electron due to the change in velocity, $\Delta \mathbf{v}$, is given by Eq. (20) of Purcell [1].

$$
\begin{equation*}
\Delta \mathbf{i}=\frac{e \Delta \mathbf{v}}{2 \pi r} \tag{27.5}
\end{equation*}
$$

And, the total change in current, $\Delta \mathbf{i}$, is:

$$
\begin{equation*}
\Delta \mathbf{i}=N W t \frac{e \Delta \mathbf{v}}{2 \pi r} \tag{27.6}
\end{equation*}
$$

where $N$ is the density of current carrying electrons in the current ring cross section, $W$ is the width of the current ring, and $t$ is the thickness of the ring.

The resistance change, $\Delta R$, follows from Eqs. (27.4) and (27.6) where

$$
\begin{equation*}
\Delta R=\frac{\Delta V}{\Delta i}=\frac{2 \pi r m_{e} \Delta v^{2}}{N W t 2 e e \Delta v}=\frac{\pi r m_{e} \Delta v}{N W t e^{2}} \tag{27.7}
\end{equation*}
$$

Substitution of $\Delta v$ given by Eq. (27.1) into Eq. (27.7) gives the change in resistance corresponding to the magnetoresistance:

$$
\begin{equation*}
\Delta R=\frac{\pi r^{2} B}{N W t 2 e} \tag{27.8}
\end{equation*}
$$

An additional critically damped, overdamped, or underdamped oscillatory resistive term may arise due to both the magnetoresistance and the vector potential of the electron. The electron possesses an angular momentum of $\hbar$. As shown in the Electron g Factor section, the electron angular momentum comprises kinetic and vector potential components. Angular momentum is conserved in the presence of an applied magnetic field when the electron links flux in units of the magnetic flux quantum, $\Phi_{0}$.

$$
\begin{equation*}
\Phi_{0}=\frac{h}{2 e} \tag{27.9}
\end{equation*}
$$

This occurs when the electron rotates by $\frac{\pi}{2}$ radians about an axis perpendicular to the axis parallel to the magnetic flux lines. This electron rotation corresponds to an $\frac{\hbar}{2}$ magnitude, $180^{\circ}$, rotation of the electron's angular momentum vector. In the case that the electrons carry current, this change in momentum of a given current carrying electron increases or decreases the current depending on the vector projection of the momentum change onto the direction of the current. Recently, it has been demonstrated that 50 -nm-diameter rings of InAs on a GaAs surface can host a single circulating electron in a pure quantum state, that is easily controlled by magnetic fields and voltages on nearby plates. The electrons were observed to link flux in the unit of the magnetic flux quantum with a gain in a unit of angular momentum in a specific direction with the linkage [2].

At low temperature, the de Broglie wavelength of an electron,

$$
\begin{equation*}
\lambda=\frac{h}{m_{e} v} \tag{27.10}
\end{equation*}
$$

has macroscopic dimensions, and the electron scattering length for a given electron in a current carrying ring may be comparable to the dimensions of the ring. A current carrying ring having a magnetic field applied perpendicularly to the plane of the ring may be constructed and operated at a temperature, current, and applied magnetic field strength such that resonance occurs between the vector potential of a current carrying electron and the flux of the applied magnetic field. This coupling can give rise to a contribution to the resistance, which behaves as an underdamped harmonic oscillator in response to the applied magnetic flux. The general form of the equation for this component of the resistance is the product of an exponential dampening function and a harmonic function as given by Fowles [3]. Each electron links flux only in units of the magnetic flux quantum, $\Phi_{0}$, given by Eq. (27.9). Thus, the natural frequency in terms of the applied flux, $\Phi$, is the magnetic flux quantum, $\Phi_{0}$. According to Eq. (27.8), the magnetoresistance is proportional to the applied flux $\Phi$ where:

$$
\begin{equation*}
\Phi=\pi r^{2} B \tag{27.11}
\end{equation*}
$$

Thus, the argument of the dampening function is proportional to $\frac{\Phi}{\Phi_{0}}$. Furthermore, the magnetoresistance gives rise to a distribution of electron velocity changes centered about the average velocity change given by Eq. (27.1) where each electron's current contributing drift velocity along the ring contributes a component to the kinetic term of the electron's angular momentum. The distribution of velocity changes, dampens the coupling between each electron vector potential and the applied magnetic flux at the natural frequency corresponding to the average electron velocity. And, each electron de Broglie wavelength change corresponding to its velocity change alters the electron-lattice scattering cross section, which also contributes to the dampening of the oscillatory resistance behavior. The argument of the dampening function is the product of $\frac{\Phi}{\Phi_{0}}$ and the corresponding dimensionless damping factor, $\alpha_{D}$, which incorporates both dampening effects. The underdamped oscillatory resistance change due to the applied magnetic field is:

$$
\begin{equation*}
\Delta R=\frac{\pi r^{2} B}{N W t 2 e} e^{-\alpha_{D}\left[\frac{\Phi}{\Phi_{0}}\right]} \cos 2 \pi \frac{\Phi}{\Phi_{0}} \tag{27.12}
\end{equation*}
$$

The total resistance change due to the applied field is the sum of the magnetoresistance and the underdamped oscillatory resistance where:

$$
\begin{equation*}
\Delta R=\frac{\pi r^{2} B}{N W t 2 e}\left[1+e^{-\alpha_{D}\left[\frac{\Phi}{\Phi_{0}}\right]} \cos 2 \pi \frac{\Phi}{\Phi_{0}}\right] \tag{27.13}
\end{equation*}
$$

This type of contribution to the resistance that is an oscillatory function of the applied flux with a period of $\Phi_{0}=\frac{h}{2 e}$ is known as the Aharonov-Bohm Effect. The resistance contribution given by Eq. (27.13) is consistent with the observed behavior [4] as shown in Figure 27.1.

Figure 27.1. The change in the resistance divided by the resistance as a function of the applied flux that demonstrates the Aharonov-Bohm effect.

## Chapter 28

## CREATION OF MATTER FROM ENERGY

[The general result of particle production equations and relationships derived in the Pair Production and Gravity sections are given herein.]

Matter and energy are interconvertible and are in essence different states of the same entity. The state, matter or energy, is determined by the laws of nature and the properties of spacetime. A photon propagates according to Maxwell's Equations at the speed of light in spacetime having intrinsic impedance $\eta$. Matter, as a fundamental particle, is created in spacetime from a photon. Matter obeys the laws of Special Relativity, the relationship of motion to spacetime, and spacetime is curved by matter according to the laws of General Relativity. Relationships must exist between these laws and the implicit fundamental constants. The fundamental elements which determine the evolution of the Universe are the fundamental constants of spacetime, $\varepsilon_{o}$ and $\mu_{o}$ with the property of charge; the capacity of spacetime to be curved by mass-energy; and the photon's angular momentum of $\hbar$. The conversion of energy into matter requires a transition state for which the identification of the entity as matter or energy is impossible. From the properties of the entity, as matter or energy, and from the physical laws and the properties of spacetime, the transition state hereafter called a transition state orbitsphere are derived. Concomitantly, the equations for the interconversion of matter and energy are determined, and the fundamental constant relationships are determined exactly. The results are: matter and energy possess mass; matter possesses charge, and energy is stored in the electric and magnetic fields of matter as a consequence of its charge and the motion of its charge. Matter can trap photons as an absorption event. The mass of the matter possessing a "trapped photon" increases by the mass-energy of the photon, and the photon acts as if it possesses charge. (The electric field of "trapped photons" is given in the Excited States of the One-Electron Atom (Quantization) section). Photons obey Maxwell's Equations. At the two-dimensional surface of the orbitsphere containing a "trapped photon," the relationship between the photon's electric field and its charge at the orbitsphere (See Eq. 2.10) is:

$$
\begin{equation*}
\mathbf{n} \bullet\left(\mathbf{E}_{1}-\mathbf{E}_{2}\right)=\frac{\sigma}{\varepsilon_{0}} \tag{28.1}
\end{equation*}
$$

Thus, the photon's electric field acts as surface charge. This property of a photon is essential because charge arises from electromagnetic radiation in the creation of matter. Furthermore, energy is proportional to the mass of matter as given by:

$$
\begin{equation*}
E=m c^{2} \tag{28.2}
\end{equation*}
$$

And, energy is proportional to angular frequency as given by Planck's equation,

$$
\begin{equation*}
E=\hbar \omega \tag{28.3}
\end{equation*}
$$

It is shown in the Gravity section (Eq. (32.29)) that the de Broglie relationship can be derived from Planck's equation,

$$
\begin{equation*}
\lambda=\frac{h}{m v} \tag{28.4}
\end{equation*}
$$

Matter and light obey the wave equation relationship,

$$
\begin{equation*}
v=\lambda \frac{\omega}{2 \pi} \tag{28.5}
\end{equation*}
$$

and Eqs. (28.2) through (28.4). Light and matter exist as orbitspheres, as given in the Photon Equation section and the OneElectron Atom section, respectively.

The boundary condition for nonradiation by a transition state orbitsphere is:

$$
\begin{equation*}
2 \pi\left(r_{n}^{*}\right)=2 \pi\left(n r_{1}^{*}\right)=n \lambda_{1}^{*}=\lambda_{n}^{*} \tag{28.6}
\end{equation*}
$$

where $r^{*}$ and $\lambda^{*}$ are allowed radii and allowed wavelengths for the transition state matter in question, and $n$ is a positive real number. A general relationship derived for the electron in the Pair Production section is that when $r=\alpha a_{o}, v$ of Eq. (28.5) of a transition state orbitsphere equals the velocity of light in the inertial reference frame of the photon of angular frequency $\omega^{*}$ and energy $\hbar \omega^{*}=m_{e} c^{2}$ which forms the transition state orbitsphere of rest mass $m_{e}$. Substitution of Eq. (28.4) into Eq. (28.6) with $v=c$ and $r^{*}=\alpha a_{0}$ (See Spacetime Fourier Transform of the Electron Function and the Determination of Orbitsphere Radii sections) gives the result that the radius of the transition state orbitsphere is the Compton wavelength bar, $\lambda_{c}$, which gives the general condition for particle production where:

$$
\begin{equation*}
r_{\alpha}^{*}=\alpha a_{0}=\lambda_{c}=\frac{\hbar}{m_{0} c} \tag{28.7}
\end{equation*}
$$

With the substitution of Eq. (28.7) and the appropriate special relativistic corrections into the orbitsphere energy equations, the following energies, written in general form, are equal to:

$$
\begin{equation*}
E=\hbar \omega^{*}=m_{0} c^{2}=V \tag{28.8}
\end{equation*}
$$

where $V$ is the potential energy. In the case of an electron orbitsphere, the rest mass $m_{0}=m_{e}$, the radius $r_{\alpha}^{*}=\alpha a_{o}$, and the electron and positron each experience an effective charge of:
$\alpha^{-1} e$.

$$
\begin{equation*}
V=\frac{\alpha^{-1} e^{2}}{4 \pi \varepsilon_{0} \alpha a_{0}} \tag{28.9}
\end{equation*}
$$

This energy and mass are that of the transition state orbitsphere which can be considered to be created from the photon of angular frequency $\omega^{*}$. Furthermore, the relativistic factor, $\gamma$,

$$
\begin{equation*}
\gamma=\frac{1}{\sqrt{1-\left(\frac{v}{c}\right)^{2}}} \tag{28.10}
\end{equation*}
$$

for the lab frame relative to the photon frame of the transition state orbitsphere of radius $\alpha a_{0}$ is $2 \pi$ where Eq. (28.10) is transformed from Cartesian coordinates to spherical coordinates ${ }^{1}$. (For example, the relativistic mass of the electron transition state orbitsphere of radius $\alpha a_{0}$ is $2 \pi m_{e}$. See the Special Relativistic Correction to the Ionization Energies section.) Using the relativistic mass, the Lorentz invariance of charge, and the radius of the transition state orbitsphere as $\alpha a_{0}$, it is demonstrated in the Pair Production section that the electrical potential energy is equal to the energy stored in the magnetic field which gives the following equalities of energies written in general form where:

$$
\begin{equation*}
E=V=E_{m a g}=\hbar \omega^{*}=m_{0} c^{2} \tag{28.11}
\end{equation*}
$$

The energy stored in the electric and magnetic fields of any photon are equal, and equivalence of these energies occurs for an LC circuit excited at its resonance angular frequency,

$$
\begin{equation*}
\omega^{*}=\frac{1}{\sqrt{L C}} \tag{28.12}
\end{equation*}
$$

where $L$ is the inductance and $C$ is the capacitance of the circuit. Spacetime is an LC circuit with resonance angular frequency

[^48]The de Broglie wave length is given by Eq. (1.38)

$$
\lambda_{n}=\frac{h}{p_{n}}=\frac{h}{m_{e} v_{n}}
$$

In the relativistically corrected case given by Eq. (1.16),

$$
r_{n}=\lambda_{n}
$$

Then from Eq. (1.38),

$$
r_{n}=\lambda_{n}=\frac{h}{p_{n}}=\frac{h}{\left(2 \pi m_{e}\right) v_{n}}
$$

Thus, the relativistically corrected electron mass in the mass density is $2 \pi m_{e}$. Alternatively, with the wavelength in the speed of light frame given by Eq. (1.16), the relativistic invariance of the angular momentum of the electron of $\hbar$ (Eq. (1.37)) gives the corresponding electron mass as $2 \pi m_{e}$.

$$
\begin{equation*}
\omega^{*}=\frac{1}{\sqrt{L C}}=\frac{1}{\sqrt{\varepsilon_{0} \mu_{0} d^{2}}}=\frac{1}{\sqrt{\varepsilon_{0} \mu_{0} \lambda_{C}^{2}}} \tag{28.13}
\end{equation*}
$$

where $d$ is the circuit dimensions. (This equation is derived in the Pair Production section.) For $d=\alpha a_{o}$, this frequency is equivalent to that of a photon of energy $m_{e} c^{2}$. When the resonance frequency of an LC circuit is excited, the impedance becomes infinite. Thus, spacetime is excited at its resonance frequency when a photon of angular frequency $\omega^{*}$ forms a transition state orbitsphere of mass-energy $m_{e} c^{2}$. At this event, the equivalence of all energies given previously provides that matter and energy are indistinguishable. (For the transition state orbitsphere, the potential energy corresponds to the stored electrical energy of an LC circuit, which in turn corresponds to the energy stored in the electric field of a photon.) The impedance for the propagation of electromagnetic radiation becomes infinite and a photon of energy $m_{e} c^{2}$ becomes a fundamental particle as the transition state orbitsphere becomes real. The energy of the photon is equal to the rest mass of the particle at zero potential energy. Therefore, in the case of charged particle production, a particle and an antiparticle each of mass $\frac{\hbar \omega^{*}}{c^{2}}$ are produced at infinity relative to the mutual central field of:

$$
\begin{equation*}
\mathbf{E}=\frac{+e}{4 \pi \varepsilon_{0} r^{2}} \tag{28.14}
\end{equation*}
$$

And momentum is conserved by a third body, such as an atomic nucleus.
The boundary condition, Eq. (1.15) and Eq. (28.6), precludes the existence of the Fourier components of the currentdensity function of the orbitsphere that are synchronous with waves traveling at the speed of light. The nonradiative condition is Lorentz invariant because the velocity is perpendicular to the radius. However, the constancy of the speed of light must also hold which requires relativistic corrections to spacetime. The Schwarzschild metric gives the relationship whereby matter causes relativistic corrections to spacetime that determines the curvature of spacetime and is the origin of gravity. Thus, the creation of matter causes local spacetime to become curved. The geometry of spacetime is transformed from flat (Euclidean) to curved (Riemannian). Time and distances are distorted. At particle production, the proper time of the particle must equal the coordinate time given by Special Relativity for Riemannian geometry affected by the creation of matter of mass $m_{0}$ where the metric of spacetime is given by the Schwarzschild metric. This boundary condition determines the masses of the fundamental particles.

The gravitational radius, $\alpha_{G}$ or $r_{G}$, which arises from the solution of the Schwarzschild metric is defined as

$$
\begin{equation*}
\alpha_{G}=\frac{G m_{0}}{c^{2}}=r_{G} \tag{28.15}
\end{equation*}
$$

where $G$ is the gravitational constant. The radius of the transition state orbitsphere is:

$$
\begin{equation*}
r_{\alpha}^{*}=\lambda_{c}=\frac{\hbar}{m_{0} c} \tag{28.16}
\end{equation*}
$$

These radii are equal when the gravitational potential, $E_{\text {grav }}$, is:

$$
\begin{equation*}
E_{g r a v}=\frac{G m_{0}^{2}}{r_{\alpha}^{*}}=\frac{G m_{0}^{2}}{\lambda_{c}}=\hbar \omega^{*}=V=E_{m a g} \tag{28.17}
\end{equation*}
$$

These relationships represent the unification of the fundamental laws of the Universe, Maxwell's Equations, Newtonian Mechanics, Special and General Relativity, and the Planck equation and the de Broglie relationship where the latter two can be derived from Maxwell's Equations as demonstrated in the Gravity section.

## Chapter 29

## PAIR PRODUCTION

The conversion of energy into matter requires a transition state for which the identification of the entity as matter or energy is impossible. From the properties of the entity, as matter or energy, and from the physical laws and the properties of spacetime, the transition state hereafter called a transition state orbitsphere is derived. For example, a photon of energy 1.02 MeV in the presence of a third particle becomes a positron and an electron. This phenomenon, called pair production, involves the conservation of mass-energy, charge, and angular and linear momentum. Pair production occurs as an event in spacetime where all boundary conditions are met according to the physical laws: Maxwell's Equations, Newton's Laws, and Special and General Relativity, where matter and energy are indistinguishable by any physical property. Matter and photons exist as orbitspheres; thus, the conversion of energy to matter must involve the orbitsphere equations derived in the previous sections. It must also depend on the equations of electromagnetic radiation and the properties of spacetime because matter is created from electromagnetic radiation as an event in spacetime.

Matter and light obey the wave equation relationship,

$$
\begin{equation*}
v=\lambda \frac{\omega}{2 \pi} \tag{29.1}
\end{equation*}
$$

The boundary condition for nonradiation by a transition state orbitsphere is:

$$
\begin{equation*}
2 \pi\left(r_{n}^{*}\right)=2 \pi\left(n r_{1}^{*}\right)=n \lambda_{1}^{*}=\lambda_{n}^{*} \tag{29.2}
\end{equation*}
$$

where $r^{*}$ and $\lambda^{*}$ are allowed radii and allowed wavelengths for the transition state matter in question, and $n$ is a positive real number.

Consider the production of an electron and a positron providing a mutual central field. The relationship between the potential energy of an electron orbitsphere and the angular velocity of the orbitsphere is:

$$
\begin{equation*}
V=\hbar \omega^{*}=\frac{1}{n} \frac{e^{2}}{4 \pi \varepsilon_{0} n a_{0}} \tag{29.3}
\end{equation*}
$$

It can be demonstrated that the velocity of the electron orbitsphere satisfies the relationship for the velocity of a wave by substitution of Eqs. (1.15) and (1.36) into Eq. (29.1), which gives Eq. (1.35). Similarly, the relationship between $c$, the velocity of light in free space, and angular frequency, $\omega$, and wavelength, $\lambda$, is:

$$
\begin{equation*}
c=\lambda \frac{\omega}{2 \pi} \tag{29.4}
\end{equation*}
$$

And, the energy of a photon of angular frequency, $\omega$, is:

$$
\begin{equation*}
E=\hbar \omega \tag{29.5}
\end{equation*}
$$

Recall from the Excited States of the One Electron (Quantization) section that a photon of discrete angular frequency, $\omega$, can be trapped in the orbitsphere of an electron which serves as a resonator cavity of radius $r_{n}$ where the resonance excitation energy of the cavity is given by Eq. (29.3).

As demonstrated in the Excited States of the One-Electron Atom (Quantization) section, with the inclusion of the contribution of the electron kinetic energy change, the change in the orbitsphere angular velocity is equal to the angular velocity of the resonant photon of the corresponding electron transition. For the initial conditions of an unbound electron at rest, the ratio of the linear velocity of the subsequently bound electron to the emitted free-space photon is given by Eq. (29.4).

$$
\begin{equation*}
\frac{v_{n}}{c_{\text {photon }}}=\frac{\lambda_{n} \frac{\omega_{n}}{2 \pi}}{\lambda_{\text {photon }} \frac{\omega_{\text {photon }}}{2 \pi}}=\frac{\lambda_{n}}{\lambda_{\text {photon }}}=\frac{\pi r_{n}}{r_{\text {photon }}} \tag{29.6}
\end{equation*}
$$

where the $n$ subscripts refer to orbitsphere quantities and the far-right-hand-side relationship follows from Eq. (2.2) and Eq. (4.12).

Consider a transition state electron orbitsphere, which is defined as the transition state between light and matter where light and matter are indistinguishable and the linearly propagating photon becomes a stationary spherical standing wave that only possesses light speed of rotation along field lines ${ }^{1}$. For this case, the velocity of the electron transition state orbitsphere is the speed of light in the inertial reference frame of the photon, which formed the transition state orbitsphere. The result of the substitution into Eq. (29.1) of $c$ for $v$, of $\lambda_{n}$ given by Eq. (2.2) where $r_{1}$ is given by Eq. (1.257) for $\lambda$, and of $\omega_{n}$ given by Eq. (1.36) for $\omega$ is:

$$
\begin{equation*}
c=2 \pi n a_{0} \frac{\hbar}{m_{e}\left(n a_{0}\right)^{2} 2 \pi} \tag{29.7}
\end{equation*}
$$

Maxwell's Equations provide that

$$
\begin{equation*}
c=\sqrt{\frac{1}{\varepsilon_{0} \mu_{0}}} \tag{29.8}
\end{equation*}
$$

The result of substitution of Eqs. (1.256) and (29.8) into Eq. (29.7) is:

$$
\begin{equation*}
n^{-1}=\frac{m_{e} c a_{0}}{\hbar}=\frac{m_{e}}{\hbar \sqrt{\varepsilon_{0} \mu_{0}}} \frac{4 \pi \varepsilon_{0} \hbar^{2}}{e^{2} m_{e}}=4 \pi \sqrt{\frac{\varepsilon_{0}}{\mu_{0}}} \frac{\hbar}{e^{2}}=\alpha^{-1} \tag{29.9}
\end{equation*}
$$

In fact, $\alpha$ is the fine structure constant (a dimensionless constant for pair production) [1]. The experimental value is 0.0072973506 . Recently, alterations to the most up-to-date, self consistent set of the recommended values of the MKS basic constants and conversion factors of physics and chemistry resulting from the 1986 least-squares adjustment have been proposed [2]. Eq. (29.9), the equations of pair production given below, and the equations in the Unification of Spacetime, the Forces, Matter, and Energy section and Gravity section permit the derivation of a more accurate self-consistent set.

Continuing with the present MKS units, the radius of the transition state electron orbitsphere is $\alpha a_{0}$, and the potential energy, $V$, is given by Eq. (29.3) where $n=\alpha$ where $\alpha$ arises from Gauss' law surface integral and the relativistic invariance of charge where:

$$
\begin{align*}
& V=\frac{-\alpha^{-2} e^{2}}{4 \pi \varepsilon_{0} a_{0}}  \tag{29.10}\\
& V=m_{e} c^{2} \tag{29.11}
\end{align*}
$$

Furthermore, the result of the multiplication of both sides of Eq. (1.36) by $\hbar, r_{n}=n a_{0}$, and the substitution of $n=\alpha$ yields

$$
\begin{equation*}
\hbar \omega_{\alpha}^{*}=m_{e} c^{2} \tag{29.12}
\end{equation*}
$$

The relativistic factor,

$$
\begin{equation*}
\gamma=\frac{1}{\sqrt{1-\left(\frac{v}{c}\right)^{2}}} \tag{29.13}
\end{equation*}
$$

for an orbitsphere at radius $r_{\alpha}^{*}$ ( $\alpha a_{0}$ in the case of the electron) is $2 \pi$ where Eq. (29.13) is transformed from Cartesian coordinates to spherical coordinates. (See the Special Relativistic Correction to the Ionization Energies section.) The energy stored in the magnetic field of the electron orbitsphere is:

$$
\begin{equation*}
E_{m a g}=\frac{\pi \mu_{0} e^{2} \hbar^{2}}{\left(m_{e}\right)^{2} r_{n}^{3}} \tag{29.14}
\end{equation*}
$$

Eq. (29.15) is the result of the substitution of $\alpha a_{0}$ for $r_{n}$, the relativistic mass, $2 \pi m_{e}$, for $m_{e}$, and multiplication by the relativistic correction, $\alpha^{-1}$, which arises from Gauss' law surface integral and the relativistic invariance of charge.

[^49]where $T$ is the period of motion such that
\[

$$
\begin{equation*}
2 \pi r_{\text {photon }}=c T=\lambda \tag{3}
\end{equation*}
$$

\]

corresponding to a match with the particle radius and wavelength in the transition state.

$$
\begin{equation*}
E_{\operatorname{mag}}=m_{e} c^{2} \tag{29.15}
\end{equation*}
$$

Thus, the energy stored in the magnetic field of the transition state electron orbitsphere equals the electrical potential energy of the transition state orbitsphere. The magnetic field is a relativistic effect of the electrical field; thus, equivalence of the potential and magnetic energies when $v=c$ is given by Special Relativity where these energies are calculated using Maxwell's Equations. The energy stored in the electric and magnetic fields of a photon are equivalent. The corresponding equivalent energies of the transition state orbitsphere are the electrical potential energy and the energy stored in the magnetic field of the orbitsphere.

Spacetime is an electrical LC circuit with an intrinsic impedance of exactly,

$$
\begin{equation*}
\eta=\sqrt{\frac{\mu_{0}}{\varepsilon_{0}}}=376.730519 \Omega \tag{29.16}
\end{equation*}
$$

The lab frame circumference of the transition state electron orbitsphere is $2 \pi \alpha a_{0}$; whereas, the circumference for the $v=c$ inertial frame is $\alpha a_{0}$. The relativistic factor for the radius of $\alpha a_{0}$ is $2 \pi$ as shown in the Spacetime Fourier Transform of the Electron Function section, the Relativistic Correction to the Ionization Energies section, and the Spin-Orbit Coupling section; thus, due to relativistic length contraction, the total capacitance of free space of the transition state orbitsphere of radius $\alpha a_{0}$ is:

$$
\begin{equation*}
C=\frac{2 \pi \alpha a_{0} \varepsilon_{0}}{2 \pi}=\varepsilon_{0} \alpha a_{0} \tag{29.17}
\end{equation*}
$$

where $\varepsilon_{0}$ is the capacitance of spacetime per unit length $(F / m)$. Similarly, the inductance is:

$$
\begin{equation*}
L=\frac{2 \pi \alpha a_{0} \mu_{0}}{2 \pi}=\mu_{0} \alpha a_{0} \tag{29.18}
\end{equation*}
$$

where $\mu_{0}$ is the inductance per unit length ( $\mathrm{H} / \mathrm{m}$ ).
Thus, the resonance angular frequency of a transition state electron orbitsphere is:

$$
\begin{equation*}
\omega^{*}=\frac{1}{\sqrt{L C}}=\frac{1}{\sqrt{\varepsilon_{0} \alpha a_{0} \mu_{0} \alpha a_{0}}} \tag{29.19}
\end{equation*}
$$

Thus,

$$
\begin{equation*}
\omega^{*}=\frac{m_{e} c^{2}}{\hbar} \tag{29.20}
\end{equation*}
$$

Thus, the LC resonance frequency of free space for a transition state electron orbitsphere equals the frequency of the photon, which forms the transition state orbitsphere.

The impedance of any LC circuit goes to infinity when it is excited at the resonance frequency. Thus, the electron transition state orbitsphere is an LC circuit excited at the corresponding resonance frequency of free space. The impedance of free space becomes infinite, and electromagnetic radiation cannot propagate. At this event, the frequency, wavelength, velocity, and energy of the transition state orbitsphere equal that of the photon. The energy of the photon is equal to the rest mass-energy of the particle at zero potential energy, and charge is conserved. Therefore, a free electron and a free positron each of mass $\frac{\hbar \omega^{*}}{c^{2}}$ are produced at infinity relative to the mutual central field of:

$$
\begin{equation*}
\mathbf{E}=\frac{+e}{4 \pi \varepsilon_{0} r^{2}} \tag{29.21}
\end{equation*}
$$

where all of the electron transition state orbitsphere equations developed herein apply to this central field. The equation of the free electron is given in the Electron in Free Space section. The transition state is equivalent to the equation of the photon given in the Photon Equation section. Photons superimpose; thus, pair production occurs with a single photon of energy equal to twice the rest mass of an electron. Linear momentum is conserved by a third body such as a nucleus which recoils in the opposite direction as the particle pair; thus, permitting pair production to occur.

For pair production, angular momentum is conserved. All photons carry $\pm \hbar$ of angular momentum, and the angular momentum of all matter as orbitspheres is $\pm \hbar$; see Eq. (1.37). The radius of particle creation is $\alpha r_{1}^{*}$. This radius is equal to $\lambda_{c}$, the Compton wavelength bar, where $\lambda_{c}=\frac{\hbar}{m_{e} c}$. It arises naturally from the boundary condition of no radiation, Eq. (1.15) and Eq. (29.2) where $n=\alpha$, the de Broglie relationship, Eq. (1.38), and that the velocity of the transition state orbitsphere equals $c$.

$$
\begin{equation*}
r_{\alpha}^{*}=\frac{\hbar}{m_{e} c}=\lambda_{c} \tag{29.22}
\end{equation*}
$$

A schematic of the pair-production process of photon to transition state to free electron-positron pair is shown in Figure 29.1A-
E. In addition, a free positron and electron may form a bound state with a radius of $2 a_{0}$ called positronium that exists for a fraction of a second before decaying into two 510 keV photons in opposite directions. Positronium is discussed in the corresponding section.

Figure 29.1. Pair Production. (A) A linearly polarized photon of energy 1.02 MeV comprising the superposition of two oppositely circularly-polarized photons collides with a third body such as a proton. (B) The photon transforms into a transition state intermediate between matter and energy. (C) The photon forms a two-dimensional spherical shell of mass $2 m_{e}$ with the same radius as the photon, the electron Compton-wavelength bar $\left(\lambda_{c}\right)$. The shell comprises the superposition of the positron and the electron of opposite charges and each having $\hbar$ of total angular momentum. (D) The transition state ionizes. (E) Free particles propagate in different directions with linear momentum conserved.

The equations derived for the electron in the present section are generally applicable to all fundamental particles, and it is shown in the Gravity section that the masses of the fundamental particles are determined by these equations and the curvature of spacetime by matter. During the creation of matter, the constancy of the speed of light must hold which requires relativistic corrections to spacetime. The Schwarzschild metric gives the relationship whereby matter causes relativistic corrections to spacetime that determines the curvature of spacetime and is the origin of gravity. Thus, the creation of matter causes local spacetime to become curved. The geometry of spacetime is transformed from flat (Euclidean) to curved (Riemannian). Time and distances are distorted. At particle production, the proper time of the particle must equal the coordinate time given by Special Relativity for Riemannian geometry affected by the creation of matter of mass $m_{0}$ (in the case of pair production, $m_{0}=m_{e}$ ) where the metric of spacetime is given by the Schwarzschild metric. This boundary condition determines the masses of the fundamental particles.

## Chapter 30

## POSITRONIUM

Pair production, the creation of a positron/electron pair, occurs such that the radius of one orbitsphere has a radius infinitesimally greater than the radius of the antiparticle orbitsphere as discussed in the Pair Production section and the Leptons section. In addition, a free positron and electron may form a bound state with a radius of $2 a_{0}$ called positronium that exists for a fraction of a second before decaying into two 510 keV photons in opposite directions. The sequence of events is shown in Figures $30.1 \mathrm{~A}-\mathrm{E}$.

As shown in Figures 30.1A-B, a minimum energy is obtained by the binding of a positron and an electron as concentric orbitspheres at the same radius to form a short-lived hydrogen-like atom wherein the electric fields mutually cancel and the $\hbar$ of angular momentum of each lepton is conserved. Before annihilation, positronium can exist with the electron and positron spins parallel or antiparallel called orthopositronium $\left({ }^{3} S_{1}\right)$ and parapositronium $\left({ }^{1} S_{0}\right)$, respectively. Due to the opposite charge of the positron, the magnetic moments are opposed to the spin orientations. The respective decay times are 1 ns and $1 \mu \mathrm{~s}$. The splitting of the spectral lines due to spin orientations is called the hyperfine structure of positronium.

The forces of positronium are central, and the radius of the outer orbitsphere (electron or positron) is calculated as follows. The centrifugal force is given by Eq. (1.241). The centripetal electric force of the inner orbitsphere on the outer orbitsphere is given by Eq. (1.242). A second centripetal force is the relativistic corrected magnetic force, $\mathbf{F}_{\text {mag }}$, between each point of the particle and the antiparticle given by Eq. (1.252) with $m_{e}$ substituted for $m$. The force balance equation is given by Eq. (1.253) with $m_{e}$ substituted for $m$. The balance between the centrifugal and electric and magnetic forces is given in the Excited States of the One-Electron Atom (Quantization) section and the Excited States of Helium section:

$$
\begin{align*}
& \frac{m_{e} v^{2}}{r_{1}}=\frac{\hbar^{2}}{m_{e} r_{1}^{3}}=\frac{e^{2}}{4 \pi \varepsilon_{0} r_{1}^{2}}-\frac{\hbar^{2}}{m_{e} r_{1}^{3}}  \tag{30.1}\\
& r_{1}=\frac{4 \pi \varepsilon_{0} \hbar^{2}}{e^{2} \mu} \tag{30.2}
\end{align*}
$$

where $r_{1}=r_{2}$ is the radius of the positron and the electron and where the reduced mass, $\mu$, is:

$$
\begin{equation*}
\mu=\frac{m_{e}}{2} \tag{30.3}
\end{equation*}
$$

The Bohr radius given by:

$$
\begin{equation*}
a_{0}=\frac{4 \pi \varepsilon_{0} \hbar^{2}}{e^{2} m_{e}} \tag{30.4}
\end{equation*}
$$

and Eq. (30.3) is substituted into Eq. (30.2) to give the ground-state radius of positronium:
$r_{1}=2 a_{0}$

Figure 30.1. Formation and Annihilation of Positronium. (A) A free positron and electron are mutually attracted by the Coulombic force. (B) A positron and an electron form a bound state called positronium that exists as a two-dimensional spherical shell of mass $2 m_{e}$ with a radius of $2 a_{0}$. The particle provides the central force for the antiparticle. The shell comprises the superposition of the positron and the electron of opposite charges and each having $\hbar$ of total angular momentum. Transitions between ortho and para magnetic states may occur. (C) The pair transforms into a transition state intermediate between matter and energy. (D) The annihilation is complete as two oppositely circularly-polarized photons each of 510 keV and having a radius of twice the electron Compton-wavelength bar ( $\lambda_{C}$ ) (not to scale) propagate in opposite directions.

## EXCITED STATE ENERGIES

The potential energy $V$ between the particle and the antiparticle having the radius $r_{1}$ given by Eq. (1.261) is:

$$
\begin{equation*}
V=\frac{-e^{2}}{4 \pi \varepsilon_{0} r_{1}}=\frac{-Z^{2} e^{2}}{8 \pi \varepsilon_{0} a_{0}}=-2.18375 \times 10^{-18} \mathrm{~J}=13.59 \mathrm{eV} \tag{30.6}
\end{equation*}
$$

The calculated ionization energy is $\frac{1}{2} V$ (Eqs. (1.262-1.264)) which is:

$$
\begin{equation*}
E_{\text {ele }}=6.795 \mathrm{eV} \tag{30.7}
\end{equation*}
$$

The experimental ionization energy is 6.795 eV .
Parapositronium, a singlet state hydrogen-like atom comprising an electron and a positron, can absorb a photon which excites the atom to the first triplet state, orthopositronium. In parapositronium, the electron and positron angular momentum vectors are antiparallel; whereas, the magnetic moment vectors are parallel. The opposite relationships exist for orthopositronium. The balance between the centrifugal and electric and magnetic forces is:

$$
\begin{align*}
& \frac{m_{e} v^{2}}{r_{n}}=\frac{\hbar^{2}}{m_{e} r_{n}^{3}}=\frac{1}{n} \frac{e^{2}}{4 \pi \varepsilon_{0} r_{n}^{2}}-\frac{\hbar^{2}}{m_{e} r_{n}^{3}}  \tag{30.8}\\
& r_{n}=n 2 a_{0} \tag{30.9}
\end{align*}
$$

where $n$ is an integer and both electrons are at the same excited state radius of $r_{n}=n 2 a_{0}$. The principal energy levels for the singlet excited states are given by Eq. (2.22) and Eq. (9.12) with the electron reduced mass (Eq. (30.3)) substituted for the mass of the electron where

$$
\begin{equation*}
E_{n}=\frac{1}{n} \frac{e^{2} \mu}{8 \pi \varepsilon_{0} r_{n}}=\frac{1}{n} \frac{e^{2} \mu}{8 \pi \varepsilon_{0} n a_{0}}=\frac{6.795}{n^{2}} \mathrm{eV} \tag{30.10}
\end{equation*}
$$

The levels given by Eq. (30.10) match the experimental energy levels.

## HYPERFINE STRUCTURE

As shown in the Orbitsphere Equation of Motion For $\ell=0$ Based on the Current Vector Field (CVF) section, the angular momentum of the electron or positron orbitsphere in a magnetic field comprises the initial $\frac{\hbar}{2}$ projection on the z-axis and the initial $\frac{\hbar}{4}$ vector component in the xy-plane that precesses about the z -axis. As further shown in the Magnetic Parameters of the Electron (Bohr Magneton) section, a resonant excitation of the Larmor precession frequency gives rise to an additional component of angular momentum which is consistent with Maxwell's equations. As shown in the Excited States of the OneElectron Atom (Quantization) section, conservation of the $\hbar$ of angular momentum of a trapped photon can give rise to $\hbar$ of electron angular momentum along the $\mathbf{S}$-axis. The photon standing waves of excited states are spherical harmonic functions which satisfy Laplace's equation in spherical coordinates and provide the force balance for the corresponding charge (mass)density waves. Consider the photon in the case of the precessing electron with a Bohr magneton of magnetic moment along the $\mathbf{S}$-axis. The radius of the orbitsphere is unchanged, and the photon gives rise to current on the surface that satisfies the condition:

$$
\begin{equation*}
\nabla \cdot J=0 \tag{30.11}
\end{equation*}
$$

corresponding to a rotating spherical harmonic dipole [1] that phase-matches the current (mass) density of Eq. (1.144). Thus, the electrostatic energy is constant, and only the magnetic energy need be considered as given by Eqs. (30.14-30.15). The corresponding central field at the orbitsphere surface given by the superposition of the central field of the lepton and that of the photon follows from Eqs. (2.10-2.17) and Eq. (17) of Box 1.1:

$$
\begin{equation*}
\mathbf{E}=\frac{e}{4 \pi \varepsilon_{0} r^{2}}\left[Y_{0}^{0}(\theta, \phi) \mathbf{i}_{\mathbf{r}}+\operatorname{Re}\left\{Y_{\ell}^{m}(\theta, \phi) e^{i \omega_{n} t}\right\} \mathbf{i}_{\mathbf{y}} \delta\left(r-r_{1}\right)\right] \tag{30.12}
\end{equation*}
$$

where the spherical harmonic dipole $Y_{\ell}^{m}(\theta, \phi)=\sin \theta$ is with respect to the $\mathbf{S}$-axis. The dipole spins about the $\mathbf{S}$-axis at the angular velocity given by Eq. (1.36). The resulting current is nonradiative as shown in Appendix I: Nonradiation Condition. Thus, the field in the RF rotating frame is magnetostatic, as shown in Figures 1.28 and 1.29 , but directed along the $\mathbf{S}$-axis.

The application of a magnetic field with a resonant Larmor excitation gives rise to a precessing angular momentum vector $\mathbf{S}$ of magnitude $\hbar$ directed from the origin of the orbitsphere at an angle of $\theta=\frac{\pi}{3}$ relative to the applied magnetic field. $\mathbf{S}$ rotates about the axis of the applied field at the Larmor frequency. The magnitude of the components of $\mathbf{S}$ that are parallel and orthogonal to the applied field (Eqs (1.129-1.130)) are $\frac{\hbar}{2}$ and $\sqrt{\frac{3}{4}} \hbar$, respectively. Since both the RF field and the orthogonal components shown in Figure 1.25 rotate at the Larmor frequency, the RF field that causes a Stern Gerlach transition produces a stationary magnetic field with respect to these components as described by Patz [2].

The component of Eq. (1.130) adds to the initial $\frac{\hbar}{2}$ parallel component to give a total of $\hbar$ in the stationary frame corresponding to a Bohr magneton, $\mu_{B}$, of magnetic moment. The potential energy of a magnetic moment $\mathbf{m}$ in the presence of flux $\mathbf{B}$ [3] is:

$$
\begin{equation*}
E=\mathbf{m} \cdot \mathbf{B} \tag{30.13}
\end{equation*}
$$

The angular momentum of the electron gives rise to a magnetic moment of $\mu_{B}$. Thus, the energy $\Delta E_{\operatorname{mag}}^{\text {spin }}$ to switch from parallel to antiparallel to the field is given by Eq. (1.168) :

$$
\begin{equation*}
\Delta E_{\operatorname{mag}}^{s p i n}=2 \mu_{\mathbf{B}} \mathbf{i}_{\mathbf{z}} \cdot \mathbf{B}=2 \mu_{B} B \cos \theta=2 \mu_{B} B \tag{30.14}
\end{equation*}
$$

$\Delta E_{\text {mag }}^{\text {spin }}$ is also given by Planck's equation. It can be shown from conservation of angular momentum considerations (Eqs. (2632) of Box 1.1) that the Zeeman splitting is given by Planck's equation and the Larmor frequency based on the gyromagnetic ratio (Eq. (2) of Box 1.1). The electron's magnetic moment may only be parallel or antiparallel to the magnetic field rather than at a continuum of angles including perpendicular according to Eq. (30.13). No continuum of energies predicted by Eq. (30.13) for a pure magnetic dipole is possible. The energy difference for the magnetic moment to flip from parallel to antiparallel to the applied field is:

$$
\begin{equation*}
\Delta E_{\operatorname{mag}}^{s p i n}=2 \hbar \omega_{L} \tag{30.15}
\end{equation*}
$$

corresponding to magnetic dipole radiation wherein $\omega_{L}$ is the Larmor angular frequency.
Eq. (30.13) implies a continuum of energies; whereas, Eq. (29) of Box 1.1 shows that the static-kinetic and dynamic vector potential components of the angular momentum are quantized at $\frac{\hbar}{2}$. Consequently, as shown in the Electron g Factor section, the flux linked during a spin transition is quantized as the magnetic flux quantum:

$$
\begin{equation*}
\Phi_{0}=\frac{h}{2 e} \tag{30.16}
\end{equation*}
$$

Only the states corresponding to:

$$
\begin{equation*}
m_{s}= \pm \frac{1}{2} \tag{30.17}
\end{equation*}
$$

are possible due to conservation of angular momentum. It is further shown using the Poynting power vector with the requirement that flux is linked in units of the magnetic flux quantum, that the factor 2 of Eqs. (30.14) and (30.15) is replaced by the electron $g$ factor. From Eqs. (1.226-1.227), the energy $\Delta E_{\text {mag }}^{\text {spin }}$ to flip the electron's magnetic moment from parallel to antiparallel to the applied field is:

$$
\begin{align*}
& \Delta E_{\text {mig }}^{\text {spin }}=2\left(1+\frac{\alpha}{2 \pi}+\frac{2}{3} \alpha^{2}\left(\frac{\alpha}{2 \pi}\right)-\frac{4}{3}\left(\frac{\alpha}{2 \pi}\right)^{2}\right) \mu_{B} B  \tag{30.18}\\
& \Delta E_{\text {mag }}^{\text {spin }}=g \mu_{B} B \tag{30.19}
\end{align*}
$$

The spin-flip transition can be considered as involving a magnetic moment of $g$ times that of a Bohr magneton. The calculated value of $\frac{g}{2}$ is 1.001159652 137. The experimental value [4] of $\frac{g}{2}$ is 1.001159652 188(4).

Positronium undergoes a Stern-Gerlach transition. The energy of the transition from orthopositronium $\left({ }^{3} S_{1}\right)$ to parapositronium ( ${ }^{1} S_{0}$ ) is the hyperfine structure interval. The angular momentum of the photon given by $\mathbf{m}=\int \frac{1}{8 \pi c} \operatorname{Re}\left[\mathbf{r} \times\left(\mathbf{E} \times \mathbf{B}^{*}\right)\right] d x^{4}=\hbar$ in the Photon section is conserved [5] for the solutions for the resonant photons and hyperfine-state lepton functions as shown for the cases of one-electron atoms and helium in the Excited States of the OneElectron Atom (Quantization) section and the Excited States of Helium section, respectively. To conserve the $\hbar$ of angular momentum of each lepton and the photon, orthopositronium possesses orbital angular momentum states corresponding to $m_{\ell}=0, \pm 1$; whereas, parapositronium possesses orbital angular momentum states corresponding to the quantum number $m_{\ell}=0$. The orbital angular momentum states of orthopositronium are degenerate in the absence of an applied magnetic field. As in the case of the electron Stern-Gerlach transition, the radius of both leptons remains at the same radius of $r=2 a_{0}$ given by Eq. (30.5).

The hyperfine structure interval of positronium can be calculated from the spin-spin and spin-orbit coupling energies of the ${ }^{3} S_{1} \rightarrow{ }^{1} S_{0}$ transition using the procedure given in the Two-Electron Atoms section and Appendix VI. The vector projection of the orbitsphere angular momentum on the z-axis is $\mathbf{L}_{z}=\frac{\hbar}{2}$ (Eq. (1.128)) with an orthogonal component of $\mathbf{L}_{x y}=\frac{\hbar}{4}$ (Eq. (1.127)). The magnetic flux, B, of the electron (positron) at the positron (electron) due to $\mathbf{L}_{z}$ after McQuarrie [3] (Eqs. (2.183) and (7.6)) is:

$$
\begin{equation*}
\mathbf{B}=\frac{\mu_{0} \hbar}{2 m_{e} r^{3}} \tag{30.20}
\end{equation*}
$$

where $\mu_{0}$ is the permeability of free-space ( $4 \pi \times 10^{-7} N / A^{2}$ ). The spin-spin coupling energy $\Delta E_{\text {spinspin }}$ between the inner orbitsphere and the outer orbitsphere is given by Eq. (1.227) where $\mu_{B}$, the magnetic moment of the outer orbitsphere is given by Eq. (1.169). Substitution of Eqs. (1.169) and (30.20) into Eq. (30.19) gives:

$$
\begin{equation*}
\Delta E_{\text {spinsspin }}=\frac{1}{2} \frac{g \mu_{0} e^{2} \hbar^{2}}{4 m_{e}^{2} r_{1}^{3}}=\frac{g \mu_{0} e^{2} \hbar^{2}}{8 m_{e}^{2}\left(2 a_{0}\right)^{3}}=\frac{1}{8 \pi \alpha} \frac{g \alpha^{5}(2 \pi)^{2}}{8} m_{e} c^{2} \tag{30.21}
\end{equation*}
$$

where the factor of $1 / 2$ arises from Eq. (30.13) with the presence of the magnetic flux only for the ${ }^{1} S_{0}$ state, the radius is given by Eq. (30.5), and Eqs. (2.183-2.194) were used to convert Eq. (30.21) to the electron mass-energy form of Eq. (30.22).

In the case of atomic hydrogen with $n=2$, the radius given by Eq. (2.2) is $r=2 a_{0}$, and the predicted energy difference
between the ${ }^{2} P_{3 / 2}$ and ${ }^{2} P_{1 / 2}$ levels of the hydrogen atom, $E_{s / o}$, is:

$$
\begin{equation*}
E_{s / o}=\frac{\alpha^{5}(2 \pi)^{2}}{8} m_{e} c^{2} \sqrt{\frac{3}{4}} \tag{30.22}
\end{equation*}
$$

In the case of the hyperfine transition of positronium, the spin-orbit coupling energy $\Delta E_{s / o}\left({ }^{3} S_{1} \rightarrow{ }^{1} S_{0}\right)$ having $r=2 a_{0}$ is given by Eq. (2.194) with the requirement that the flux from the partner lepton is linked in units of the magnetic flux quantum corresponding to the anomalous $g$ factor (Eqs. (30.18-30.19)), the source current given by Eq. (30.12) gives rise to a factor of $3 / 2$, and each lepton contributes to the energy:

$$
\begin{equation*}
\Delta E_{s / o}\left({ }^{3} S_{1} \rightarrow{ }^{1} S_{0}\right)=2 \frac{3}{2} \frac{g \alpha^{5}(2 \pi)^{2}}{8} m_{e} c^{c^{2}} \sqrt{\frac{3}{4}} \tag{30.23}
\end{equation*}
$$

The hyperfine structure interval of positronium $\left({ }^{3} S_{1} \rightarrow{ }^{1} S_{0}\right)$ is given by the sum of Eqs. (30.21) and (30.23).

$$
\begin{align*}
\Delta E_{\mathrm{Ps} \text { hyperfine }} & =\Delta E_{\text {spin-spin }}+\Delta E_{s / o}\left({ }^{3} S_{1} \rightarrow{ }^{1} S_{0}\right) \\
& =\frac{g \mu_{0} e^{2} \hbar^{2}}{8 m_{e}^{2}\left(2 a_{0}\right)^{3}}+\frac{3 g \alpha^{5}(2 \pi)^{2}}{8} m_{e} c^{2} \sqrt{\frac{3}{4}} \\
& =\frac{g \alpha^{5}(2 \pi)^{2}}{8} m_{e} c^{2}\left(\frac{1}{8 \pi \alpha}+\frac{3 \sqrt{3}}{2}\right)  \tag{30.24}\\
& =8.41155110 \times 10^{-4} \mathrm{eV}
\end{align*}
$$

Using Planck's equation (Eq. (2.148)), the interval in frequency, $\Delta v$, is:

$$
\begin{equation*}
\Delta v=203.39041 \mathrm{GHz} \tag{30.25}
\end{equation*}
$$

The experimental ground-state hyperfine structure interval [6] is:

$$
\begin{align*}
& \Delta E_{\text {Ps hyperfine }}(\text { experimental })=8.41143 \times 10^{-4} \mathrm{eV}  \tag{30.26}\\
& \Delta v(\text { experimental })=203.38910(74) \mathrm{GHz}(3.6 \mathrm{ppm})
\end{align*}
$$

There is remarkable (six significant figure) agreement between the calculated and experimental values of $\Delta v$ that is only limited by the accuracy of the fundamental constants [7].

# Chapter 31 

## RELATIVITY

## BASIS OF A THEORY OF RELATIVITY ${ }^{1}$

To describe any phenomenon such as the motion of a body or the propagation of light, a definite frame of reference is required. A frame is a certain base consisting of a defined origin and three axes equipped with graduated rulers and clocks. Bodies in motion then have definite positions and definite motions with respect to the base. The motion of planets is commonly described in the heliocentric system. The origin is defined as the mass center, and the three axes are chosen to point to three fixed stars to establish the fixed orientation of the axes. In general, the mathematical form of the laws of nature will be different in different frames. For example, the motion of bodies relative to the Earth may be described either in a frame with axes pointing to three fixed stars or in one rigidly fixed to the Earth. In the latter case, Coriolis forces arise in the equations of motion. There exist frames of reference in which the equations of motion have a particular simple form; in a certain sense these are the most "natural" frames of reference. They are the inertial frames in which the motion of a body is uniform and rectilinear, provided no forces act on $\mathrm{it}^{2}$. In pre-relativistic physics the notion of an inertial system was related only to the laws of mechanics. Newton's first law of motion is, in fact, nothing but a definition of an inertial frame. Similarly, Newton's second law gives the relationship of a force acting on a mass and its acceleration relative to certain frame of reference. Newton introduced the concept of absolute space to provide an absolute frame for acceleration and rotation as well as uniform motion. According to Newton, acceleration and rotation relative to absolute space are detected by simple experiments. But, it was believed that there is no such means to identify an absolute frame for uniform motion ${ }^{3}$.

The relativity principle is postulated on the basis of the impossibility of measuring absolute velocity. This assumption is incorrect. Absolute space can be defined based on the solution of the exact conserved relationships between matter, energy, and spacetime given in the Equivalence of Inertial and Gravitational Masses Due to Absolute Space and Absolute Light Velocity section. Specifically, the production of an isolated particle from a photon of identically the production energy defines the absolute inertial frame at rest for the particle and could, in principle, define absolute space that conserves the energy inventory of the Universe and resolves paradoxes such as the twin paradox [1-2]. But, even though any motion, or parameter of inertia or electromagnetism can ultimately be measured in principle (but perhaps not always in practice) relative to absolute space, a principle of relativity based on physical laws can be derived that has great utility. The principle of relativity given next treats relative motion, and the transforms of relativity are Lorentzian.

Since the constant speed of light is the absolute limiting conversion factor from time to length, it is reasonable to expect that the laws of light propagation play a fundamental part in the definition of the basic concepts relating to space and time in terms of inertial frames defined according to uniform relative motion. Therefore it proves more correct to relate the notion of an inertial frame not only to the laws of mechanics but also to those of light propagation.

The usual form of Maxwell's equations refers to some inertial frame. It is obvious and has always been assumed, even before relativity, that at least one reference frame exists that is inertial with respect to mechanics and in which at the same time Maxwell's equations are true. The law of propagation of an electromagnetic wave front in the form:

[^50]\[

$$
\begin{equation*}
\frac{1}{c^{2}}\left(\frac{\partial^{2} \omega}{\partial t^{2}}\right)-\left[\left(\frac{\partial^{2} \omega}{\partial x^{2}}\right)+\left(\frac{\partial^{2} \omega}{\partial y^{2}}\right)+\left(\frac{\partial^{2} \omega}{\partial z^{2}}\right)\right]=0 \tag{31.1}
\end{equation*}
$$

\]

also refers to this inertial frame. A frame for which Eq. (31.1) is valid may be called inertial in the electromagnetic sense. A frame that is inertial both in the mechanical and in the electromagnetic senses will be simply called inertial.

Thus, by the definition we have adopted, an inertial frame is characterized by the following two properties:

1. In an inertial frame, a body moves uniformly and in a straight line, provided no forces act on it. (The usual mechanical inertial property.)
2. In an inertial frame, the equation of propagation of an electromagnetic wave front has the form Eq. (31.1). (The inertial property for the field.)

Eq. (31.1) applies not only to the propagation of an electromagnetic wave. The electromagnetic field has no preference over other fields. The maximum speed of propagation of all fields must be the same such that Eq. (31.1) is of universal validity.

The fundamental postulate of the theory of relativity, also called the principle of relativity, asserts that phenomena occurring in a closed system are independent of any non-accelerated motion of the system as a whole. The principle of relativity asserts that the two sequences of events will be exactly the same (at least insofar as they are determined at all). If a process in the original systems can be described in terms of certain functions of the space and time coordinates of the first frame, the same functions of the space and time coordinates of the second frame will describe a process occurring in the copy. The uniform rectilinear motion of a material system as a whole has no influence on the course of any process occurring within it.

The theory of relativity is based on two postulates, namely, the principle of relativity and another principle that states that the velocity of light is independent of the velocity of its source. The latter principle is a consequence of the first. The latter principle is implicit in the law of the propagation of an electromagnetic wave front given by Eq. (31.1). The basis for defining inertial reference frames is Eq. (31.1) together with the fact of the uniform rectilinear motion of a body not subject to forces. The principle of relativity holds in the case that the reference frames are inertial.

It is appropriate to give a generalized interpretation of the law of wave front propagation and to formulate the following general postulate:

## There exists a maximum speed for the propagation of any kind of action-the speed of light in free space.

This principle is very significant because the transmission of signals with greatest possible speed plays a fundamental part in the definition of concepts concerning space and time. The very notion of a definite frame of reference for describing events in space and time depends on the existence of such signals. The principle formulated above, by asserting the existence of a general upper limit for all kinds of action and signal, endows the speed of light with a universal significance, independent of the particular properties of the agency of transmission and reflecting a certain objective property of spacetime. This principle has a logical connection with the principle of relativity. For if there was no single limiting velocity but instead different agents, e.g. light and gravitation, propagated in vacuum with different speeds, then the principle of relativity would necessarily be violated as regards at least one of the agents. The principle of the universal limiting velocity can be made mathematically precise as follows:

For any kind of wave advancing with limiting velocity and capable of transmitting signals, the equation of front propagation is the same as the equation for the front of a light wave.

Thus, the equation:

$$
\begin{equation*}
\frac{1}{c^{2}}\left(\frac{\partial^{2} \omega}{\partial t^{2}}\right)-\left(\operatorname{grad}^{2} \omega\right)=0 \tag{31.2}
\end{equation*}
$$

acquires a general character; it is more general than Maxwell's equations from which Maxwell originally derived it. As a consequence of the principle of the existence of a universal limiting velocity one can assert the following: the differential equations describing any field that is capable of transmitting signals must be of such a kind that the equation of their characteristics is the same as the equation for the characteristics of light waves. In addition to governing the propagation of any form of energy, the wave equation governs fundamental particles created from energy and vice versa, the associated effects of mass on spacetime, and the evolution of the Universe itself. The equation that describes the electron rotational energy and angular momentum given by Eqs. (1.56-1.65) is the wave equation, the relativistic correction of spacetime due to particle production travels according to the wave equation as given in the Gravity section, and the evolution of the Universe is according to the wave equation as given in the Gravity section and the Unification of Spacetime, the Forces, Matter, and Energy section (Eqs. (33.45-33.36)).

The presence of a gravitational field somewhat alters the appearance of the equation of the characteristics from the form of Eq. (31.2), but in this case one and the same equation still governs the propagation of all kinds of wave fronts traveling with limiting velocity, including electromagnetic and gravitational ones. The basis for defining inertial reference frames is Eq. (31.2) asserting the universality of the equation together with the fact of the uniform rectilinear motion of a body not subject to forces.

Let one and the same phenomenon be described in two inertial frames of reference. The question arises of relating measurements in one frame to those in another. For example, consider transforming radar data obtained by a satellite circling the Earth to that recorded on the ground. For such a transformation, the relationship between the space and time coordinates $x, y, z$ and $t$ in the first frame and the corresponding $x^{\prime}, y^{\prime}, z^{\prime}$ and $t^{\prime}$ in the second. Before relativity one accepted as selfevident the existence of a universal time $t$ that was the same for all frames. In this case $t^{\prime}=t$ or $t^{\prime}=t-t_{0}$, if a change of time origin was used. Considering two events occurring at $t^{\prime}$ and $\tau$, the old point of view required the time elapsed between them to be the same in all reference frames so that:

$$
\begin{equation*}
t-\tau=t^{\prime}-\tau^{\prime} \tag{31.3}
\end{equation*}
$$

Furthermore, it was considered to be evident that the length of a rigid rod, measured in the two frames, would have the same value. (This applies equally to the distance between the "simultaneous" positions of two points that need not necessarily be rigidly connected.) Denoting the spatial coordinates of the two ends of the rod (or the two points) by $(x, y, z)$ and $(\xi, \eta, \zeta)$ in the one frame and by $\left(x^{\prime}, y^{\prime}, z^{\prime}\right)$ and $\left(\xi^{\prime}, \eta^{\prime}, \zeta^{\prime}\right)$ in the other, the old theory required:

$$
\begin{equation*}
(x-\xi)^{2}+(y-\eta)^{2}+(z-\zeta)^{2}=\left(x^{\prime}-\xi^{\prime}\right)^{2}+\left(y^{\prime}-\eta^{\prime}\right)^{2}+\left(z^{\prime}-\zeta^{\prime}\right)^{2} \tag{31.4}
\end{equation*}
$$

Eqs. (31.3) and (31.4) determine uniquely the general form of the transformation connecting $x, y, z$ and $t$ with $x^{\prime}, y^{\prime}, z^{\prime}$ and $t^{\prime}$. It consists of a change in origin of spatial coordinates and of time, of a rotation of the spherical axes, and of a transformation such as:

$$
\begin{align*}
& x^{\prime}=x-V_{x} t \\
& y^{\prime}=y-V_{y} t  \tag{31.5}\\
& z^{\prime}=z-V_{z} t \\
& t^{\prime}=t
\end{align*}
$$

where $V_{x}, V_{x}$, and $V_{x}$ are the constants of velocity with which the primed frame moves relative to the unprimed one; more exactly they are the components of this velocity in the unprimed frame. The transformation (Eq. (31.5)) is known as a Galileo transformation. Thus, pre-relativistic physics asserted that, given an inertial frame ( $x, y, z$ ), space and time coordinates in any other frame moving uniformly and rectilinearly relative to the former are connected by a Galileo transformation, apart from a displacement of the origin.

Galileo transformations satisfy the principle of relativity as far as the laws of (Newtonian) mechanics are concerned, but not in relation to the propagation of light. Indeed the wave front equation changes its appearance when subjected to a Galileo transformation. If Galileo transformations were valid and the Principle of Relativity in its generalized form was not, then there would exist only one inertial system as defined above. The changed form of the wave front equation in any other frame would allow one to detect even uniform rectilinear motion relative to the single inertial system-the "immobile ether"-and to determine the velocity of this motion. Experiments devised to discover such motion relative to the "ether" have unquestionably eliminated the "ether" as a possibility and confirm that the form of the law of wave front propagation is the same in all nonaccelerated frames ${ }^{4}$. Therefore the principle of relativity is certainly also applicable to electromagnetic phenomena. It also follows that the Galileo transformation is in general wrong and should be replaced by another. The problem can be stated as follows. Let a reference frame be given which is inertial according to the definition given above (i.e. both mechanically and electromagnetically). The space time coordinates in this frame are given by $x, y, z$ and $t$. Let the space time coordinates in another inertial frame be given by ( $x^{\prime}, y^{\prime}, z^{\prime}, t^{\prime}$ ). The connection between ( $x, y, z, t$ ) and ( $x^{\prime}, y^{\prime}, z^{\prime}, t^{\prime}$ ) is to be found. The problem of finding a transformation between two inertial frames is purely mathematical; it can be solved without any further physical assumptions other than the definition of an inertial frame given above. The transformations are given by Lorentz.

[^51]
## LORENTZ TRANSFORMATIONS

A Lorentz transformation is a set of equations for transforming the space and time coordinates in one inertial frame into those of another that moves uniformly and in a straight line relative to the first. The transformation can be characterized by the fact that the quantity,

$$
\begin{equation*}
d s^{2}=d x_{0}^{2}-\left(d x_{1}^{2}+d x_{2}^{2}+d x_{3}^{2}\right) \tag{31.6}
\end{equation*}
$$

or

$$
\begin{equation*}
d s^{2}=c^{2} d t^{2}-\left(d x^{2}+d y^{2}+d z^{2}\right) \tag{31.7}
\end{equation*}
$$

remains invariant in the strict sense (not only the numerical value, but also the mathematical form of the expression remain unchanged). Newtonian mechanics is corrected by Lorentz transformations of the time, length, mass, momentum, and energy of an object. Newtonian mechanics with Galileo transforms give mechanical forces for $v \ll c$ :

$$
\begin{align*}
& \mathbf{F}=\frac{d \mathbf{p}}{d t}=\frac{d(m \mathbf{v})}{d t}=m \frac{d \mathbf{v}}{d t}=m \mathbf{a}  \tag{31.8}\\
& T=\frac{1}{2} m v^{2} \tag{31.9}
\end{align*}
$$

In the case that $v$ approaches $c$, Lorentz transforms apply.

## TIME DILATION

## THE RELATIVITY OF TIME

The postulates of relativity may be used to derive the Lorentz transformation that described how relative motion affects measurements of time intervals.

A clock that moves with respect to an observer appears to tick less rapidly than it does when at rest with respect to him. That is, if someone in a spacecraft finds that the time interval between two events in the spacecraft is $t_{0}$, we on the ground would find that the same interval has the longer duration $t$. The quantity $t_{0}$, which is determined by events that occur at the same place in a observer's frame of reference, is called the proper time of the interval between the events. When witnessed from the ground, the events that mark the beginning and end of the time interval occur at different places, and as a consequence the duration of the interval appears longer than the proper time. This effect is called time dilation (to dilate is to become larger).

To see how time dilation comes about, let us consider two clocks of the particularly simple kind shown in Figure 31.1.
Figure 31.1. A simple clock. Each "tick" corresponds to a round trip of the light pulse from the lower mirror to the upper one and back.

Such a clock consists of a stick $L_{0}$ long with a mirror at each end. A pulse of light is reflected up and down between the mirrors, and a device attached to one of them produces a "tick" of some kind each time the light pulse strikes it. Such a device might be a photosensitive coating on the mirror that gives an electric signal when the pulse arrives.

One clock is at rest in a laboratory on the ground and the other is in a spacecraft that moves at the velocity $v$ relative to the ground. An observer in the laboratory watches both clocks and finds that they tick at different rates.

Figure 31.2 shows the laboratory clock in operation. The time interval between ticks is the proper time $t_{0}$. The time needed for the light pulse to travel between the mirrors at the speed of light, $c$, is $\frac{t_{0}}{2}$; hence $\frac{t_{0}}{2}=\frac{L_{0}}{c}$ and

$$
\begin{equation*}
t_{0}=\frac{2 L_{0}}{c} \tag{31.10}
\end{equation*}
$$

Figure 31.3 shows the moving clock with its mirrors perpendicular to the direction of motion relative to the ground.

Figure 31.2. A light-pulse clock at rest on the ground as seen by an observer on the ground. The dial represents a conventional clock on the ground.

Figure 31.3. A light-pulse clock in a spacecraft as seen by an observer on the ground. The mirrors are parallel to the direction of motion of the spacecraft. The dial represents a conventional clock on the ground.

The time interval between ticks is $t$. Because the clock is moving, the light pulse, as seen from the ground, follows a zigzag path. On its way from the lower mirror to the upper one in the time $\frac{t}{2}$, the pulse travels a horizontal distance of $v \frac{t}{2}$ and a total distance of $c \frac{t}{2}$. Since $L_{0}$ is the vertical distance between the mirrors,

$$
\begin{align*}
& \left(c \frac{t}{2}\right)^{2}=L_{0}^{2}+\left(v \frac{t}{2}\right)^{2}  \tag{31.11}\\
& \frac{t^{2}}{4}\left(c^{2}-v^{2}\right)=L_{0}^{2}  \tag{31.12}\\
& t^{2}=\frac{4 L_{0}^{2}}{c^{2}-v^{2}}=\frac{\left(2 L_{0}\right)^{2}}{c^{2}\left(1-\frac{v^{2}}{c^{2}}\right)}  \tag{31.13}\\
& t=\frac{\frac{2 L_{0}}{c}}{\sqrt{1-\frac{v^{2}}{c^{2}}}} \tag{31.14}
\end{align*}
$$

But $\frac{2 L_{0}}{c}$ is the time interval $t_{0}$ between ticks on the clock on the ground, as in Eq. (31.10), and so the time dilation relationship is:

$$
\begin{equation*}
t=\frac{t_{0}}{\sqrt{1-\frac{v^{2}}{c^{2}}}} \tag{31.15}
\end{equation*}
$$

wherein the parameters are:
$t_{0}=$ time interval on clock at rest relative to an observer
$t=$ time interval on clock in motion relative to an observer
$v=$ speed of relative motion
$c=$ speed of light
Because the quantity $\sqrt{1-\frac{v^{2}}{c^{2}}}$ is always smaller than 1 for a moving object, $t$ is always greater than $t_{0}$. The moving clock in the spacecraft appears to tick at a slower rate than the stationary one on the ground, as seen by an observer on the ground.

Exactly the same analysis holds for measurements of the clock on the ground by the pilot of the spacecraft. To him, the light pulse of the ground clock follows a zigzag path that requires a total time $t$ per round trip. His own clock, at rest in the spacecraft, ticks at intervals of $t_{0}$. He too finds that

$$
\begin{equation*}
t=\frac{t_{0}}{\sqrt{1-\frac{v^{2}}{c^{2}}}} \tag{31.16}
\end{equation*}
$$

so the effect is reciprocal: Every observer finds that clocks in motion relative to him tick more slowly than clocks at rest relative to him.

The Lorentz transformation of time, length, mass, momentum, and energy which are significant when $v$ approaches $c$ can be derived by a similar procedure [2]. The Lorentz transformations are:

$$
\begin{align*}
& t=\frac{t_{0}}{\sqrt{1-\frac{v^{2}}{c^{2}}}}  \tag{31.17}\\
& l=l_{o} \sqrt{1-\frac{v^{2}}{c^{2}}}  \tag{31.18}\\
& m=\frac{m_{0}}{\sqrt{1-\frac{v^{2}}{c^{2}}}}  \tag{31.19}\\
& p=\frac{m_{0} v}{\sqrt{1-\frac{v^{2}}{c^{2}}}}  \tag{31.20}\\
& E=m c^{2}=\frac{m_{0} c^{2}}{\sqrt{1-\frac{v^{2}}{c^{2}}}}  \tag{31.21}\\
& E^{2}=m_{0}^{2} c^{4}+p^{2} c^{2} \tag{31.22}
\end{align*}
$$

When speaking of the relativity of a frame of reference or simply of relativity, one usually means that there exist identical physical processes in different frames of reference. According to the generalized Galilean principle of relativity identical processes are possible in all inertial frames of reference related by Lorentz transformations. On the other hand, Lorentz transformations characterize the uniformity of Galilean spacetime.

## THE RELATIVITY PRINCIPLE AND THE COVARIANCE OF EQUATIONS IN GALILEAN OR EUCLIDEAN SPACETIME AND RIEMANN SPACETIME

From the geometrical point of view the theory of space and time naturally divides into the theory of uniform, Galilean, space and the theory of non-uniform, Riemannian, space.

Galilean space is of maximal uniformity. This means that in it:
(a) All points in space and instants in time are equivalent
(b) All directions are equivalent, and
(c) All inertial systems, moving uniformly and in a straight line relative to one another, are equivalent (Galilean principle of relativity).
The uniformity of space and time manifests itself in the existence of a group of transformations which leave the fourdimensional interval between two points (distance) invariant. The expression for this interval plays an important part in the theory of space and time because its form is directly related to the form taken by the basic laws of physics, viz. the law of motion of a free mass-point and the law of propagation in free space of the front of a light wave.

The indications (a), (b) and (c) of the uniformity of Galilean space are related to the following transformations:
(a) To the equivalence of all points and instants corresponds to the transformation of displacing the origins of the spatial coordinates and of time; the transformation involves four parameters, namely, the three space coordinates and the time coordinate of the origin.
(b) To the equivalence of all directions corresponds to the transformation of rotating the spatial coordinate axes; this involves three parameters, the three angles of rotation.
(c) To the equivalence of inertial frames corresponds to a change from one frame of reference to another moving uniformly in a straight line with respect to the first; this transformation involves three parameters, the three components of relative velocity.
The most general transformation involves ten parameters. This is the Lorentz transformation. It is well known that in a space of $n$ dimensions the group of transformations which leave invariant the expression for the squared distance between infinitely near points, can contain at most $\frac{1}{2} n(n+1)$ parameters. If there is a group involving all $\frac{1}{2} n(n+1)$ parameters then the
space is of maximal uniformity; it may be a space of constant curvature, or, if the curvature vanishes, a Euclidean or pseudoEuclidean space.

In the case of spacetime, the number of dimensions is four and therefore the greatest possible number of parameters is ten. This is also the number of parameters in the Lorentz transformation, so that Galilean space, to which the transformation relates, is indeed of maximal uniformity. It is customary to call the theory based on the Lorentz transformations the special theory of relativity. More precisely, the subject of that theory is the formulation of physical laws in accordance with the properties of Galilean space.

A formulation of the principle of relativity given supra, which together with the postulate that the velocity of light has a limiting character, may be made the basis of relativity theory. We shall now investigate in more detail the question of the connection of the physical principle of relativity with the requirement that the equations be covariant.

In the first place, we shall attempt to give a generally covariant formulation of the principle of relativity, without as yet making this concept more precise. In its most general form, the principle of relativity states the equivalence of the coordinate systems (or frames of reference) that belong to a certain class and are related by transformations of the form:

$$
\begin{equation*}
x_{\alpha}^{\prime}=f_{\alpha}\left(x_{0}, x_{1}, x_{2}, x_{3}\right) \tag{31.23}
\end{equation*}
$$

which may be stated more briefly as:

$$
\begin{equation*}
x^{\prime}=f(x) \tag{31.24}
\end{equation*}
$$

It is essential to remember that, in addition to the group of permissible transformations, the class of coordinate systems must be characterized by certain supplementary conditions. Thus, for instance, if we consider Lorentz transformations, it is selfevident that these linear transformations must connect not any arbitrary coordinates, but only the Galilean coordinates in two inertial reference frames. To consider linear transformations between any other (non-Galilean) coordinates has no sense, because the Galilean principle of relativity has no validity in relation to such artificial linear transformations. On the other hand, if one introduces any other variables in place of the Galilean coordinates, a Lorentz transformation can evidently be expressed in terms of these variables, but then the transformation formulae will have a more complicated form.

The formulation of the principle of relativity based on the equivalence of reference frames depends on the ability to call two reference frames $(x)$ and $\left(x^{\prime}\right)$ physically equivalent if phenomena proceed in the same way in them. Specifically, if a possible process is described in the coordinates $(x)$ by the functions:

$$
\begin{equation*}
\phi_{1}(x), \phi_{2}(x), \ldots, \phi_{n}(x) \tag{31.25}
\end{equation*}
$$

then there is another possible process which is describable by the same functions

$$
\begin{equation*}
\phi_{1}\left(x^{\prime}\right), \phi_{2}\left(x^{\prime}\right), \ldots, \phi_{n}\left(x^{\prime}\right) \tag{31.26}
\end{equation*}
$$

in the coordinates $\left(x^{\prime}\right)$. Conversely any process of the form Eq. (31.26) in the second system corresponds to a possible process of the form Eq. (31.25) in the first system. Thus, a relativity principle is a statement concerning the existence of corresponding processes in a set of reference frames of a certain class wherein the corresponding systems are accepted as equivalent. It is clear from this definition that both the principle of relativity itself and the equivalence of two reference frames are physical concepts, and validity of either involves a definite physical hypothesis rather than convention. In addition, it follows that the very notion of a "principle of relativity" becomes well defined only when a definite class of frames of reference has been singled out. In the usual theory of relativity, this class is that of inertial systems.

The functions Eq. (31.25) or Eq. (31.26) describing a physical process will be called field functions or functions of state. In a generally covariant formulation of the equations describing physical processes the components $g_{\mu \nu}$ of the metric tensor must be included among the functions of state such as the collection of field functions:

$$
\begin{equation*}
F_{\mu \nu}(x), \quad j_{v}(x), \quad g_{\mu \nu}(x) \tag{31.27}
\end{equation*}
$$

i.e. the electromagnetic field, the current vector, and the metric tensor, respectively. The requirement for the formulation of a principle of relativity that in two equivalent reference frames corresponding phenomena should proceed in the same way applies equally to the metric tensor. Thus, if we compare two corresponding phenomena in to physically equivalent reference frames, then for the first phenomenon, described in the old coordinates, not only the components of electromagnetic field and of current density, but also the components of the metric tensor must have the same mathematical form as for the second phenomenon described in the new coordinates.

Further conclusions depend on whether the metric is assumed to be fixed or whether phenomena that influence the metric are considered. In the usual theory of relativity, it is assumed that the metric is given, and it does not depend on any physical processes. This is also the case for the generally covariant formulation of the theory of relativity. As long as the assumption remains in force that the character of spacetime is Galilean and the $g_{\mu \nu}$ are introduced only to achieve general covariance, these quantities will depend only on the choice of coordinate system, not on the nature of the physical process discussed. They are functions of state only in a formula sense. In the theory of gravitation on the other hand, a different assumption is made concerning the nature of spacetime. There the $g_{\mu \nu}$ are functions of state, not only in a formal sense, but in fact: they describe a certain physical field, namely the field of gravitation.

To give a definite meaning to the principle of relativity in such circumstances, it is essential to specify more closely not only the class of coordinate systems, but also the nature of the physical processes for which the principle is being formulated. Starting from the assumption that the metric is fixed ("rigid"), or that it may be considered as fixed for a certain class of physical processes, consider the above definition of corresponding phenomena in two physically equivalent coordinate systems, wherein all field functions, including the components of the metric tensor, must have the same mathematical form for the first process described in the old coordinates as for the second process described in the new coordinates. If the $g_{\mu \nu}$ are independent of the nature of the physical phenomenon, then a distinction must be made between the first and second process relative to those quantities, and only transformations of the coordinates need to be considered. Thus, the quantities

$$
\begin{equation*}
g_{\mu \nu}(x) \quad \text { and } \quad g_{\mu \nu}^{\prime}\left(x^{\prime}\right) \tag{31.28}
\end{equation*}
$$

will be connected by the tensor transformation rule, and the requirement of the relativity principle that they should have one and the same mathematical form reduces (for infinitesimal coordinate transformations) to the equations $\delta g_{\mu \nu}=0$.

The most general class of transformations that satisfies these equations contains 10 parameters and is possible only in uniform spacetime, where the relation,

$$
\begin{equation*}
R_{\mu v, \alpha \beta}=K \cdot\left(g_{v \alpha} g_{\mu \beta}-g_{\mu \alpha} g_{v \beta}\right) \tag{31.29}
\end{equation*}
$$

is valid. (A space in which the curvature tensor $R_{\mu v, \alpha \beta}$ has the form of Eq. (31.29) is called a space of constant curvature; it is a four-dimensional generalization of Friedmann-Lobachevsky space. The constant $K$ is called the constant of curvature.) If in these relations, $K$ is zero, the spacetime is Galilean and the transformations in questions are Lorentz transformations, except when other (non-Galilean) coordinates are used.

Thus, with the rigidity assumption for the metric, the principle of relativity implies the uniformity of spacetime. And, if the additional condition $K=0$ holds, we obtain a Galilean metric in appropriate coordinates. The relativity principle in general form then reduces to the Galilean relativity principle. As for the condition $K=0$, it results in an additional uniformity of spacetime. If the scale of the Galilean coordinates is changed, then the scale of the elementary interval changes in the same proportion. This property implies in turn that there is no absolute scale for spacetime, unlike the absolute scale that exists for velocities in terms of the velocity of light. The absence of an absolute scale for spacetime leads conversely to the equation $K=0$.

Furthermore, taking into account phenomena that may influence the metric gives rise to the possibility that under certain conditions the principle of relativity will be valid in non-uniform space also. In this case, it is necessary that the motion of the masses producing the non-uniformity be included in the description of the phenomena.

It can be shown that under the assumption that spacetime is uniform at infinity (where it must be Galilean), a class of coordinate systems exist that are analogous to inertial systems and defined up to a Lorentz transformation. A principle of relativity will hold with respect to this class of coordinate systems in the same form as in the usual theory of relativity, despite the fact that at a finite distance from the masses the space is non-uniform. However, ultimately, this relativity principle is also a result of uniformity forced by the boundary conditions that require uniformity at infinity.

Since the greatest possible uniformity is expressed by Lorentz transformations, there is no more general principle of relativity than that discussed in ordinary relativity theory. Moreover, there cannot be a general principle of relativity, as a physical principle, which would hold with respect to arbitrary frames of reference. In order to make this fact clear, it is essential to distinguish sharply between a physical principle that postulates the existence of corresponding phenomena in different frames of reference and the simple requirement that equations should be covariant transforming from one frame of reference to another. It is clear that a principle of relativity implies a covariance of equations, but the converse is not true: covariance of differential equations is also possible when no principle of relativity is satisfied.

Covariance of equations in itself is in no way the expression of any kind of physical law. For instance, consider the mechanics of systems of mass-points. Lagrange's equations of the second kind are covariant with respect to arbitrary transformations of the coordinates. However, they do not express any new physical law compared to, for example, Lagrange's equations of the first kind, which are stated in Cartesian coordinates and are not covariant. In the case of Lagrange's equations, covariance is achieved by introducing the coefficients of the Lagrangian as new auxiliary functions considered as a quadratic expression, but not necessarily homogeneous in the velocities.

Independently considering that not all laws of nature reduce to differential equations, even fields described by differential equations not only require these equations for their definitions, but also all kinds of initial, boundary, and other conditions. These conditions are not covariant. Therefore, the preservation of their physical content requires a change in their mathematical form and, conversely, preservation of their mathematical form implies a change of their physical content. But, the realization of a process with a new physical content is an independent question that cannot be solved a priori. If "corresponding" physical processes within a given class of reference systems are possible, then a principle of relativity holds. In the opposite case, it does not. It is clear, however, that such a model representative of physical processes, and in particular such a model representative of the metric, is possible at most for a narrow class of reference systems of limited number. This argument shows once again (without invoking the concept of uniformity) that a general principle of relativity, as a physical principle, holding in relation to arbitrary frames of reference, is impossible.

A desire to find a general principle of relativity is unnecessary as a basis of the requirement of the covariance of the equations. The covariance requirement can be justified independently. It is a self-evident, purely logical requirement that in all cases in which the coordinate system is not fixed in advance, equations written down in different coordinate systems should be mathematically equivalent. The class of transformations with respect to which the equations must be covariant must correspond to the class of coordinate systems considered. Thus, if one deals with inertial systems related by Lorentz transformations and if Galilean coordinates are used, it is sufficient to require covariance with respect to Lorentz transformations. If, however, arbitrary coordinates are employed, it is necessary to demand general covariance.

It should be noted that covariance of coordinate systems acquires definite physical meaning if, and only if, a principle of relativity exists for the class of reference frames used. Such is the covariance with respect to Lorentz transformations. This concept was so useful in the formulation of physical laws because it contains concrete temporal and geometric elements (rectilinearity and uniformity of motion) and also dynamic elements (the concept of inertia in the mechanical and the electromagnetic sense). Because of this, it is related to the physical principle of relativity and itself becomes concrete and physical.

However, if arbitrary transformations are considered rather than the Lorentz transformations, one ceases to single out that class of coordinate systems relative to which the principle of relativity exists, and by doing this one destroys the connection between physics and the concept of covariance. There remains a purely logical side to the concept of covariance as a consistency requirement on equations written in different coordinate systems. Naturally this requirement is necessary, and it can always be satisfied.

In dealing with classes of reference frames that are more general than that relative to which a principle of relativity holds, the necessity arises of replacing the explicit formulation of the principle by some other statement. The explicit formulation consists of indicating a class of physically equivalent frames of reference. The new formulation must express those properties of space and time by which the principle of relativity is possible. With the assumption of a rigid metric this is achieved by introducing an additional Eq. (31.29). With the additional assumption of the absence of a universal scale $(K=0)$ these equations lead to a generally covariant formulation of the theory of relativity, without any alteration of its physical content. The Galileo-Lorentz principle of relativity is then maintained to its full extent.

The very possibility of formulating the ordinary theory of relativity in a general covariant form clearly demonstrates the difference between the principle of relativity as a physical principle and the covariance of the equations as a logical requirement. In addition, such a formulation opens the way to generalizations based on a relaxation of the assumption of a rigid metric. This relaxation provides the possibility of replacing the supplementary conditions Eq. (31.29) by others that reflect better the properties of space and time corresponding to the theory of gravitation.

Universal gravitation does not fit into the framework of uniform Galilean space because the gravitational mass of a body as well as the inertial mass depends on its energy. In the latter case, Einstein felt that it was possible to eliminate the effects of gravity by transforming to an accelerating frame of reference that defined his "Equivalence Principle." A theory of universal gravitation is derived in the Gravity section wherein Euclidean, or rather pseudo-Euclidean, geometry is abandoned in favor of the geometry of Riemann. But the derivation does not involve the traditional approach based on the Equivalence Principle; rather it is based on Eq. (31.2).

In Riemannian geometry, the coefficients $g_{\mu \nu}$ of the quadratic form for the squared infinitesimal distance are mechanics functions. These functions establish a law regarding their transformation from one coordinate frame to another based on their definition as coefficients of a quadratic form, together with the condition that this form is an invariant. Thus, a transformation of the coordinates is accompanied by a transformation of the metric $g_{\mu \nu}$ according to this law. The set of quantities $g_{\mu \nu}$ is called the metric tensor.

With the introduction of a metric tensor, expressions can be formed that are covariant with respect to any coordinate transformation. Nothing other than the covariance of equations is implicit in the metric tensors that may be obtainable from a particular one (e.g. from the Galilean tensor) by coordinate transformation. But, metric tensors of a more general form that cannot be transformed into one another by coordinate transformations are fundamentally different. In each case, the metric tensor will express not only properties of the coordinate system but also properties of space, and the latter can be related to the phenomenon of gravitation. It is shown below that the origin of gravity is the relativistic correction of spacetime itself as opposed to the relativistic correction of mass, length, and time of objects of inertial frames in constant relative motion. The production of a particle having an inertial and gravitational mass from a photon traveling at the speed of light requires time dilation and length contraction of spacetime. The present theory of gravity also maintains the constant maximum speed of light for the propagation of any form of energy including the gravitational field.

Having clarified the concept of covariance as applied to Riemannian geometry, consider it together with the previously discussed concept of the uniformity of space. As was shown above, the property of uniformity in Galilean space manifests itself in the existence of transformations that leave unchanged the expression for the four-dimensional distance between two points. More precisely, these transformations leave unchanged the coefficients of this expression, i.e. the quantities $g_{\mu \nu} \cdot g_{\mu \nu}$ are functions of the coordinates which means that the mathematical form of these functions is unchanged: The dependence of the new $g_{\mu \nu}$ on the new coordinates has the same mathematical form as that of the old $g_{\mu \nu}$ on the old coordinates. In the general case of Riemannian geometry, there are no transformations that leave the $g_{\mu \nu}$ unchanged because Riemannian space is not uniform. One deals with transformations of coordinates accompanied by transformations of the $g_{\mu \nu}$, and neither such a combined transformation nor covariance with respect to it has any relation to the uniformity or non-uniformity of space.

The geometrical properties of real physical space and time correspond not to Euclidean but to Riemannian geometry. Any deviation of geometrical properties from their Euclidean, or to be precise, pseudo-Euclidean form appears in Nature as a gravitational field. The geometrical properties are inseparably linked with the distribution and motion of ponderable matter. This relationship is mutual. On the one hand the deviations of geometrical properties from the Euclidean are determined by the presence of gravitating masses, on the other, the motion of masses in the gravitational field is determined by these deviations. In short, masses determine the geometrical properties of space and time, and these properties determine the movement of the masses. The description of the gravitational field demands the introduction of no functions other than the metric tensor itself which is uniquely determined by the presence and motion of matter. Differing from other kinds of forces, gravity which influences the motion of the matter by determining the properties of spacetime, is itself described by the metric of spacetime. For this principle of relativity, the class of coordinate systems relative to which the principle of relativity exists is the spherical coordinate systems. Spherical harmonic coordinates arise naturally due to the spherical symmetry of the particle production (energy/matter conversion) event and its effect on spacetime and provide the connection between physics and the concept of covariance as shown in the Gravity section. The corresponding metric is the Schwarzschild metric derived in the Gravity section.

The Schwarzschild metric gives the relationship whereby matter causes relativistic corrections to spacetime that determines the curvature of spacetime and is the origin of gravity. The correction is based on the boundary conditions that no signal can travel faster that the speed of light including the gravitational field that propagates following particle production from a photon wherein the particle has a finite gravitational velocity given by Newton's Law of Gravitation. The spacetime contraction during particle production is analogous to Lorentz length contraction and time dilation of an object in one inertial frame relative to another moving at constant relative velocity. In the former case, the corresponding correction is a function of the square of the ratio of the gravitational velocity to the speed of light. In the latter case, the corresponding correction is a function of the square of the ratio of the relative velocity of two inertial frames to the speed of light. Thus, the relativity principle for both Euclidean and Riemannian geometries is based on the light wave front propagation equation, specifically Eq. (31.2).
