such that the polar angle $\theta^{\prime}$ is given by

$$
\begin{equation*}
\theta^{\prime}=\cos ^{-1}\left(\frac{a}{c^{\prime}}\left(\left(a-c^{\prime}\right) \frac{1+\frac{c^{\prime}}{a}}{a_{0}}-1\right)\right) \tag{13.191}
\end{equation*}
$$

Substitution of Eqs. (13.183-13.184) into Eq. (13.191) gives:

$$
\begin{equation*}
\theta^{\prime}=123.66^{\circ} \tag{13.192}
\end{equation*}
$$

Then, the angle $\theta_{O 2 p A O}$ the radial vector of the $O 2 p \mathrm{AO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{O 2 p A O}=180^{\circ}-123.66^{\circ}=56.33^{\circ} \tag{13.193}
\end{equation*}
$$

as shown in Figure 13.2. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate
components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
a_{0} \sin \theta_{O 2 p A O}=b \sin \theta_{\mathrm{H}_{2} M O} \tag{13.194}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{\mathrm{H}_{2} M O}=\sin ^{-1} \frac{a_{0} \sin \theta_{O 2 p A O}}{b}=\sin ^{-1} \frac{a_{0} \sin 56.33^{\circ}}{b} \tag{13.195}
\end{equation*}
$$

with the use of Eq. (13.193). Substitution of Eq. (13.187) into Eq. (13.195) gives:

$$
\begin{equation*}
\theta_{\mathrm{H}_{2} \mathrm{MO}}=73.28^{\circ} \tag{13.196}
\end{equation*}
$$

Then, the distance $d_{\mathrm{H}_{2} \mathrm{MO}}$ along the internuclear axis from the origin of the $\mathrm{H}_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by

$$
\begin{equation*}
d_{\mathrm{H}_{2} \mathrm{MO}}=a \cos \theta_{\mathrm{H}_{2} \mathrm{MO}} \tag{13.197}
\end{equation*}
$$

Substitution of Eqs. (13.183) and (13.196) into Eq. (13.197) gives:

$$
\begin{equation*}
d_{\mathrm{H}_{2} M O}=0.3637 a_{0}=1.9244 \times 10^{-11} \mathrm{~m} \tag{13.198}
\end{equation*}
$$

The distance $d_{O 2 p A O}$ along the internuclear axis from the origin of the $O$ atom to the point of intersection of the orbitals is given by

$$
\begin{equation*}
d_{O 2 p A O}=c^{\prime}-d_{H_{2} M O} \tag{13.199}
\end{equation*}
$$

Substitution of Eqs. (13.184) and (13.198) into Eq. (13.199) gives:

$$
\begin{equation*}
d_{O 2 p A O}=0.5543 a_{0}=2.93343 \times 10^{-11} \mathrm{~m} \tag{13.200}
\end{equation*}
$$

In addition to the intersection of the $H_{2}$-type MO with the $O 2 p$ shell, two adjoining ellipsoidal $H_{2}$-type MOs intersect at points of equipotential. The angle and distance parameters are given by Eqs. (13.595-13.600) for the limiting methane case wherein four adjoining intersecting $H_{2}$-type MOs have the possibility of forming a self-contained two-dimensional equipotential surface of charge and current. Charge continuity can be obeyed for the $\mathrm{H}_{2} \mathrm{O}$ MO if the current is continuous between the adjoining $H_{2}$-type MOs. However, in the limiting case of methane, the existence of a separate linear combination of the $\mathrm{H}_{2}$ type MOs comprising four spin-paired electrons, not connected to the bonding carbon heteroatom requires that the electron be divisible. It is possible for an electron to form time-dependent singular points or nodes having no charge as shown by Eqs. (1.28-1.29), and two-dimensional charge distributions having Laplacian potentials and one-dimensional regions of zero charge are possible for macroscopic charge densities and currents as given in Haus and Melcher [24]. However, it is not possible for single electrons to have two-dimensional discontinuities in charge based on internal forces and first principles discussed in Appendix II. Thus, at the points of intersection of the $H_{2}$-type MOs of methane, symmetry, electron indivisibility, current continuity, and conservation of energy and angular momentum require that the current between the points of mutual contact and the carbon atom be projected onto and flow along the radial vector to the surface of the $C 2 s p^{3}$ shell. This current designated the bisector current ( BC ) meets the $C 2 s p^{3}$ surface and does not travel to distances shorter than its radius. The methane result must also apply in the case of other bonds including that of the water molecule. Here, the $H_{2}$-type MOs intersect and the ellipsoidal current is projected onto the radial vector to the $O 2 p$ shell and does not travel to distances shorter than its radius as in the case of a single $O-H$ bond.

As shown in Eq. (13.162), in addition to the $p$-orbital charge-density modulation, the uniform charge-density in the $p_{z}$ and $p_{y}$ orbitals is increased by a factor of 0.25 and the $H$ atoms are each decreased by a factor of 0.25 . Using the orbital composition of $\mathrm{H}_{2} \mathrm{O}$ (Eq. (13.162)), the radii of $O 1 s=0.12739 a_{0}$ (Eq. (10.51)), O2s $=0.59020 a_{0}$ (Eq. (10.62)), and $O 2 p=a_{0}$ (Eq. (10.162)) shells, and the parameters of the $\mathrm{H}_{2} \mathrm{O}$ MO given by Eqs. (13.3-13.4), (13.183-13.185), (13.187-13.188), and (13.192-13.200), the charge-density of the $\mathrm{H}_{2} \mathrm{O}$ MO comprising the linear combination of two $\mathrm{O}-\mathrm{H}$-bond MOs ( OH -type ellipsoidal MOs given in the Energies of $O H$ section) according to Eq. (13.162) is shown in Figure 13.4. Each $O-H$-bond MO comprises a $\mathrm{H}_{2}$-type ellipsoidal MO and an O 2 p AO having the dimensional diagram shown in Figure 13.4.

Figure 13.4. $\mathrm{H}_{2} \mathrm{O}$ MO comprising the linear combination of two $\mathrm{O}-H$-bond MOs. Each $O-H$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and the $O 2 p_{z} \mathrm{AO}$ or the $O 2 p_{y} \mathrm{AO}$ with a relative charge-density of 0.75 to 1.25 ; otherwise, the $O 2 p$ orbitals are the same as those of the oxygen atom. The internuclear axis of one $O-H$ bond is perpendicular to the bonding $p_{y}$ orbital, and the internuclear axis of the other $O-H$ bond is perpendicular to the bonding $p_{z}$ orbital. (A) Color scale, translucent view of the charge-density of the $\mathrm{H}_{2} \mathrm{O}$ MO from the top. For each $\mathrm{O}-\mathrm{H}$ bond, the ellipsoidal surface of each $H_{2}$-type ellipsoidal MO transitions to the $O 2 p$ AO. The $O 2 p$ shell, the $O 2 s$ shell, the $O 1 s$ shell, and the nuclei (red, not to scale) are shown. (B) Cut-away view showing the innermost $O 1 s$ shell, and moving radially, the $O 2 s$ shell, the $O 2 p$ shell, and the $H_{2}$-type ellipsoidal MO that transitions to the $O 2 p$ AO for each $O-H$ bond. Bisector current not shown.

## ENERGIES OF $\mathrm{H}_{2} \mathrm{O}$

The energies of $\mathrm{H}_{2} \mathrm{O}$ given by the substitution of the semiprincipal axes (Eqs. (13.183-13.185) and (13.187)) into the energy equations (Eqs. (13.172-13.180)) are:

$$
\begin{align*}
& V_{e}=\left(\frac{3}{2}\right) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-81.8715 \mathrm{eV}  \tag{13.201}\\
& V_{p}=2 \frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=29.6421 \mathrm{eV}  \tag{13.202}\\
& T=\left(\frac{3}{2}\right) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=32.3833 \mathrm{eV}  \tag{13.203}\\
& V_{m}=\left(\frac{3}{2}\right) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-16.1917 \mathrm{eV}  \tag{13.204}\\
& E_{T}\left(H_{2} O\right)=-\frac{e^{2}}{4 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-13.6181 \mathrm{eV}=-49.6558 \mathrm{eV} \tag{13.205}
\end{align*}
$$

where $E_{T}\left(\mathrm{H}_{2} \mathrm{O}\right)$ is given by Eq. (13.179) which is reiteratively matched to Eq. (13.180) within five-significant-figure round-off error.

## VIBRATION OF $\mathrm{H}_{2} \mathrm{O}$

The vibrational energy levels of $\mathrm{H}_{2} \mathrm{O}$ may be solved as two equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [2] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERM OF $\mathrm{H}_{2} \mathrm{O}$

The radiation reaction force in the case of the vibration of $\mathrm{H}_{2} \mathrm{O}$ in the transition state corresponds to the Doppler energy, $E_{D}$, given by Eq. (11.181) and Eqs. (13.22) and (13.144) that is dependent on the motion of the electrons and the nuclei. The kinetic energy of the transient vibration is derived from the corresponding central forces. As in the case of $H_{3}^{+}$, the water molecule is a linear combination of three orbitals. The water MO comprises two $H_{2}$-type ellipsoidal MOs and the $O$ AO. Thus, the force factor of water in the determination of the Doppler frequency is equivalent to that of the $H_{3}^{+}$ion given in Eqs. (13.18-13.20) and given by Eq. (13.164). From Eqs. (11.231-11.232) and (13.18-13.20), the central force terms between the electron density and the nuclei of each $O-H$-bond MO with the radius of the orbit at the oxygen atom fixed at

$$
\begin{equation*}
r_{8}=a_{0} \tag{13.206}
\end{equation*}
$$

according to Eq. (10.162) with the oscillation along the semiminor axis are:

$$
\begin{equation*}
f(b)=-\left(\frac{3}{2}\right) \frac{e^{2}}{4 \pi \varepsilon_{0} b^{2}} \tag{13.207}
\end{equation*}
$$

and

$$
\begin{equation*}
f^{\prime}(b)=\left(\frac{3}{2}\right) \frac{2 e^{2}}{4 \pi \varepsilon_{0} b^{3}} \tag{13.208}
\end{equation*}
$$

Thus, using Eqs. (11.136) and (13.207-13.208), the angular frequency of this oscillation is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\left(\frac{3}{2}\right) \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=6.24996 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{13.209}
\end{equation*}
$$

The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 6.24996 \times 10^{16} \mathrm{rad} / \mathrm{s}=41.138334 \mathrm{eV} \tag{13.210}
\end{equation*}
$$

The three basis elements of water, $H, H$, and $O$, all have the same Coulombic energy as given by Eqs. (1.264) and (10.163), respectively, such that the Doppler energy involves the total energy of the $\mathrm{H}_{2} \mathrm{O}$ MO. Thus, in Eq. (11.181), substitution of the total energy of $\mathrm{H}_{2} \mathrm{O}, E_{T}\left(\mathrm{H}_{2} \mathrm{O}\right)$, (Eqs. (13.179-13.180) and Eq. (13.181)) for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.210) for $\bar{E}_{K}$ gives the Doppler energy of the electrons for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h v} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-49.652637 \mathrm{eV} \sqrt{\frac{2 e(41.138334 \mathrm{eV})}{m_{e} c^{2}}}=-0.630041 \mathrm{eV} \tag{13.211}
\end{equation*}
$$

The total energy of $\mathrm{H}_{2} \mathrm{O}$ is decreased by $\bar{E}_{D}$.
In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. On average, the total energy of vibration is equally distributed between kinetic energy and potential energy [4]. Thus, the average kinetic energy of vibration corresponding to the Doppler energy of the electrons, $\bar{E}_{\text {Kvib }}$, is $1 / 2$ of the vibrational energy of $\mathrm{H}_{2} \mathrm{O}$. The decrease in the energy of $\mathrm{H}_{2} \mathrm{O}$ due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ and $\bar{E}_{\text {Kvib }}$. Using Eq. (13.211) and the experimental $H^{16} O H$ vibrational energy of $E_{v i b}=3755.93 \mathrm{~cm}^{-1}=0.465680 \mathrm{eV}$ [25] gives:

$$
\begin{align*}
& \bar{E}_{o s c}^{\prime}=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.212}\\
& \bar{E}_{o s c}^{\prime}=-0.630041 \mathrm{eV}+\frac{1}{2}(0.465680 \mathrm{eV})=-0.397201 \mathrm{eV} \tag{13.213}
\end{align*}
$$

per bond. As in the case for $H_{3}^{+}(1 / p)$ shown in the Doppler Energy Term of $H_{3}^{+}$-type Molecular Ions section, the reentrant orbit for the binding of a hydrogen atom to a hydroxyl radical causes the bonds to oscillate by increasing and decreasing in length along the two $O-H$ bonds at a relative phase angle of $180^{\circ}$. Since the vibration and reentrant oscillation is along two bonds for the asymmetrical stretch $\left(v_{3}\right), \bar{E}_{\text {osc }}$ for $H^{16} \mathrm{OH}, \bar{E}_{\text {osc }}\left(H^{16} \mathrm{OH}\right)$, is:

$$
\begin{equation*}
\bar{E}_{\text {osc }}\left(H^{16} O H\right)=2\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)=2\left(-0.630041 \mathrm{eV}+\frac{1}{2}(0.465680 \mathrm{eV})\right)=-0.794402 \mathrm{eV} \tag{13.214}
\end{equation*}
$$

To the extent that the MO dimensions are the same, the electron reentrant orbital energies, $\bar{E}_{K}$, are the same independent of the isotope of hydrogen, but the vibrational energies are related by Eq. (11.148). Thus, the differences in bond energies are
essentially given by $1 / 2$ the differences in vibrational energies per bond. Using Eq. (13.211), Eqs. (13.212-13.214), and the experimental $D^{16} O D$ vibrational energy of $E_{v i b}=2787.92 \mathrm{~cm}^{-1}=0.345661 \mathrm{eV}$ [25], the corresponding $\bar{E}_{\text {osc }}\left(D^{16} O D\right)$ is:

$$
\begin{equation*}
\bar{E}_{\text {osc }}\left(D^{16} O D\right)=2\left(-0.630041 \mathrm{eV}+\frac{1}{2}(0.345661 \mathrm{eV})\right)=-0.914421 \mathrm{eV} \tag{13.215}
\end{equation*}
$$

## TOTAL AND BOND ENERGIES OF $H^{16} O H$ AND $D^{16} O D$

$E_{T+o s c}\left(\mathrm{H}_{2}{ }^{16} \mathrm{O}\right)$, the total energy of the $\mathrm{H}^{16} \mathrm{OH}$ including the Doppler term, is given by the sum of $E_{T}\left(\mathrm{H}_{2} \mathrm{O}\right)$ (Eq. (13.181)) and $\bar{E}_{\text {osc }}\left(H^{16} \mathrm{OH}\right)$ given Eqs. (13.207-13.214).

$$
\begin{equation*}
E_{T+o s c}\left(H_{2}{ }^{16} O\right)=V_{e}+T+V_{m}+V_{p}+E(O 2 p)+\bar{E}_{o s c}\left(H^{16} \mathrm{OH}\right)=E_{T}\left(\mathrm{H}_{2} \mathrm{O}\right)+\bar{E}_{o s c}\left(H^{16} \mathrm{OH}\right) \tag{13.216}
\end{equation*}
$$

$$
\left.\begin{array}{rl}
E_{T+\text { osc }}\left(H_{2}{ }^{16} O\right) & \left.=\left\{\begin{array}{l}
\left(\frac{-e^{2}}{4 \pi \varepsilon_{0} c^{\prime}}\left(\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right)-13.6181 \mathrm{eV}\right) \\
+2\left(\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{array}\right) \sqrt{\frac{2 \hbar \sqrt{\frac{\frac{3}{2} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}}{m_{e} c^{2}}}\right) \tag{13.217}
\end{array}\right\}
$$

From Eqs. (13.214) and (13.216-13.217), the total energy of $H^{16} \mathrm{OH}$ is:

$$
\begin{align*}
E_{T+o s c}\left(\mathrm{H}_{2}{ }^{16} \mathrm{O}\right) & =-49.652637 \mathrm{eV}+\bar{E}_{\text {osc }}\left(\mathrm{H}^{16} \mathrm{OH}\right) \\
& =-49.652637 \mathrm{eV}-2\left(0.630041 \mathrm{eV}-\frac{1}{2}(0.465680 \mathrm{eV})\right)=-50.447039 \mathrm{eV} \tag{13.218}
\end{align*}
$$

where the experimental vibrational energy was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term. $E_{T+o s c}\left(D_{2}{ }^{16} O\right)$, the total energy of $D^{16} O D$ including the Doppler term is given by the sum of $E_{T}\left(D_{2} \mathrm{O}\right)=E_{T}\left(\mathrm{H}_{2} \mathrm{O}\right)$ (Eq. (13.181)) and $\bar{E}_{\text {osc }}\left(D^{16} \mathrm{OD}\right)$ given by Eq. (13.215):

$$
\begin{align*}
E_{T+o s c}\left(D_{2}{ }^{16} O\right) & =-49.652637 \mathrm{eV}+\bar{E}_{\text {osc }}\left(D^{16} O D\right) \\
& =-49.652637 \mathrm{eV}-2\left(0.630041 \mathrm{eV}-\frac{1}{2}(0.345661 \mathrm{eV})\right)=-50.567058 \mathrm{eV} \tag{13.219}
\end{align*}
$$

where the experimental vibrational energy was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term. As in the case of the hydroxyl radical, the dissociation of the bond of the water molecule forms a free hydrogen atom and a hydroxyl radical, with one unpaired electron each. The lowering of the energy of the reactants due to the magnetic dipoles decreases the bond energy. Thus, the total energy of oxygen is reduced by the energy in the field of the two magnetic dipoles given by Eq. (13.152). The corresponding bond dissociation energy, $E_{D}$, is given by the sum of the total energies of the corresponding hydroxyl radical and hydrogen atom minus the total energy of water, $E_{T+\text { osc }}\left(H^{16} \mathrm{OH}\right)$, and $E$ (magnetic).

Thus, $E_{D}$ of $H^{16} \mathrm{OH}$ is given by:

$$
\begin{equation*}
E_{D}\left(H^{16} \mathrm{OH}\right)=E(H)+E\left({ }^{16} \mathrm{OH}\right)-E_{T+o s c}\left(H^{16} \mathrm{OH}\right)-E(\text { magnetic }) \tag{13.220}
\end{equation*}
$$

where $E_{T}\left({ }^{16} \mathrm{OH}\right)$ is given by the sum of the experimental energies of ${ }^{16} \mathrm{O}$ (Eq. (13.171)), $H$ (Eq. (13.154)), and the negative of the bond energy of ${ }^{16} \mathrm{OH}$ (Eq. (13.157)):

$$
\begin{equation*}
E\left({ }^{16} \mathrm{OH}\right)=-13.59844 \mathrm{eV}-13.6181 \mathrm{eV}-4.41174 \mathrm{eV}=-31.62828 \mathrm{eV} \tag{13.221}
\end{equation*}
$$

From Eqs. (13.154), (13.218), and (13.220-13.221), $E_{D}\left(H^{16} \mathrm{OH}\right)$ is

$$
\begin{align*}
E_{D}\left(H^{16} \mathrm{OH}\right) & =E(H)+E\left({ }^{16} \mathrm{OH}\right)-\left(E(\text { magnetic })+E_{T+\text { osc }}\left(H^{16} \mathrm{OH}\right)\right)  \tag{13.222}\\
& =-13.59844 \mathrm{eV}-31.62828 \mathrm{eV}-(0.114411 \mathrm{eV}-50.447039 \mathrm{eV})=5.1059 \mathrm{eV}
\end{align*}
$$

The experimental $H^{16} \mathrm{OH}$ bond dissociation energy is [26]:

$$
\begin{equation*}
E_{D}\left(H^{16} \mathrm{OH}\right)=5.0991 \mathrm{eV} \tag{13.223}
\end{equation*}
$$

Similarly, $E_{D}$ of $D^{16} O D$ is given by:

$$
\begin{equation*}
E_{D}\left(D^{16} O H\right)=E(D)+E\left({ }^{16} O D\right)-\left(E(\text { magnetic })+E_{T+o s c}\left(D^{16} O D\right)\right) \tag{13.224}
\end{equation*}
$$

where $E_{T}\left({ }^{16} O D\right)$ is given by the sum of the experimental energies of ${ }^{16} O$ (Eq. (13.171)), $D$ (Eq. (13.155)), and the negative of the bond energy of ${ }^{16} O D$ (Eq. (13.159)):

$$
\begin{equation*}
E\left({ }^{16} \mathrm{OD}\right)=-13.603 \mathrm{eV}-13.6181 \mathrm{eV}-4.454 \mathrm{eV}=-31.6751 \mathrm{eV} \tag{13.225}
\end{equation*}
$$

From Eqs. (13.155), (13.220), and (13.224-13.225), $E_{D}\left(D^{16} O D\right)$ is

$$
\begin{equation*}
E_{D}\left(D^{16} O D\right)=-13.603 \mathrm{eV}-31.6751 \mathrm{eV}-(0.114411 \mathrm{eV}-50.567058 \mathrm{eV})=5.178 \mathrm{eV} \tag{13.226}
\end{equation*}
$$

The experimental $D^{16} O D$ bond dissociation energy is [27]:

$$
\begin{equation*}
E_{D}\left(D^{16} O D\right)=5.191 \mathrm{eV} \tag{13.227}
\end{equation*}
$$

## BOND ANGLE OF $\mathrm{H}_{2} \mathrm{O}$

The $\mathrm{H}_{2} \mathrm{O}$ MO comprises a linear combination of two $\mathrm{O}-\mathrm{H}$-bond MOs. Each $\mathrm{O}-\mathrm{H}$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and the $O 2 p_{z} \mathrm{AO}$ or the $O 2 p_{y} \mathrm{AO}$ with a relative charge-density of 0.75 to 1.25 ; otherwise, the $O 2 p$ orbitals are the same as those of the oxygen atom. A bond is also possible between the two H atoms of the $O-H$ bonds. Such $H-H$ bonding would decrease the $O-H$-bond strength since electron density would be shifted from the $O-H$ bonds to the $H-H$ bond. Thus, the bond angle between the two $O-H$ bonds is determined by the condition that the total energy of the $H_{2}$-type ellipsoidal MO between the terminal $H$ atoms of the $\mathrm{O}-\mathrm{H}$ bonds is zero. Since the two $H_{2}$-type ellipsoidal MOs comprise $75 \%$ of the $H$ electron density of $H_{2}$, the energies and the total energy $E_{T}$ of the $H-H$ bond is given by Eqs. (13.67-13.73). From Eq. (11.79), the distance from the origin to each focus of the $H-H$ ellipsoidal MO is

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 2 a}}=\sqrt{\frac{a a_{0}}{2}} \tag{13.228}
\end{equation*}
$$

The internuclear distance from Eq. (13.228) is:

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{\frac{a a_{0}}{2}} \tag{13.229}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal $H-H$ MO $b=c$ is given by Eq. (13.167). Substitution of Eq. (13.228) into Eq. (13.73) gives:

$$
\begin{equation*}
E_{T}=-\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right] \tag{13.230}
\end{equation*}
$$

The radiation reaction force in the case of the vibration of $H-H$ in the transition state corresponds to the Doppler energy, $E_{D}$, given by Eq. (11.181) that is dependent on the motion of the electrons and the nuclei. The total energy $E_{T}$ that includes the radiation reaction of the $H-H$ MO is given by the sum of $E_{T}$ (Eq. (13.73)) and $\bar{E}_{\text {osc }}\left(H_{2}\right)$ given by Eqs. (11.21311.220), (11.231-11.236), and (11.239-11.240). Thus, the total energy $E_{T}(H-H)$ of the $H-H$ MO including the Doppler term is

$$
\begin{align*}
E_{T} & =V_{e}+T+V_{m}+V_{p}+\bar{E}_{o s c}(H-H)  \tag{13.231}\\
E_{T} & =\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right]\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{m_{e}}{m_{e}}}}{m_{e} c^{2}}}\right]+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.232}\\
& =\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a \varepsilon_{0}}{2}}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right]\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} a^{3}}}}{m_{e}}}\right]+\frac{1}{m_{e} c^{2}} \hbar \sqrt{\frac{\frac{0.75 e^{2}}{8 \pi \varepsilon_{0} a^{3}}-\frac{e^{2}}{8 \pi \varepsilon_{0}\left(a+c^{\prime}\right)^{3}}}{0.5 m_{p}}}
\end{align*}
$$

To match the boundary condition that the total energy of the $H-H$ ellipsoidal MO is zero, $E_{T}(H-H)$ given by Eq. (13.232) is set equal to zero:

$$
\left.0=\left[\begin{array}{l}
\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right. \tag{13.233}
\end{array}\right]\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{m_{0}}{m_{e}}}}{m_{e} c^{2}}}\right]\right]
$$

From the energy relationship given by Eq. (13.233) and the relationship between the axes given by Eqs. (13.165-13.167), the dimensions of the $H-H$ MO can be solved.

The most convenient way to solve Eq. (13.233) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is

$$
\begin{equation*}
a=4.300 a_{0}=2.275 \times 10^{-10} \mathrm{~m} \tag{13.234}
\end{equation*}
$$

Substitution of Eq. (13.234) into Eq. (13.228) gives:

$$
\begin{equation*}
c^{\prime}=1.466 a_{0}=7.759 \times 10^{-11} \mathrm{~m} \tag{13.235}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.235) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.933 a_{0}=1.552 \times 10^{-10} \mathrm{~m} \tag{13.236}
\end{equation*}
$$

Substitution of Eqs. (13.234-13.235) into Eq. (13.167) gives:

$$
\begin{equation*}
b=c=4.042 a_{0}=2.139 \times 10^{-10} \mathrm{~m} \tag{13.237}
\end{equation*}
$$

Substitution of Eqs. (13.234-13.235) into Eq. (13.168) gives:

$$
\begin{equation*}
e=0.341 \tag{13.238}
\end{equation*}
$$

Using the distance between the two $H$ atoms when the total energy of the corresponding MO is zero, the corresponding bond angle can be determined from the law of cosines:

$$
\begin{equation*}
A^{2}+B^{2}-2 A B \operatorname{cosine} \theta=C^{2} \tag{13.239}
\end{equation*}
$$

With $A=B=2 c_{O-H}^{\prime}$, the internuclear distance of each $O-H$ bond given by Eq. (13.185), and $C=2 c_{H-H}^{\prime}$, the internuclear distance of the two $H$ atoms, the bond angle between the $O-H$ bonds is given by

$$
\begin{align*}
& \left(2 c_{O-H}^{\prime}\right)^{2}+\left(2 c_{O-H}^{\prime}\right)^{2}-2\left(2 c_{O-H}^{\prime}\right)^{2} \operatorname{cosine} \theta=\left(2 c_{H-H}^{\prime}\right)^{2}  \tag{13.240}\\
& \theta=\cos ^{-1}\left(\frac{2\left(2 c_{O-H}^{\prime}\right)^{2}-\left(2 c_{H-H}^{\prime}\right)^{2}}{2\left(2 c_{O-H}^{\prime}\right)^{2}}\right) \tag{13.241}
\end{align*}
$$

Substitution of Eqs. (13.185) and (13.236) into Eq. (13.241) gives:

$$
\begin{align*}
\theta & =\cos ^{-1}\left(\frac{2(1.836)^{2}-(2.933)^{2}}{2(1.836)^{2}}\right)  \tag{13.242}\\
& =\cos ^{-1}(-0.2756)=105.998^{\circ}
\end{align*}
$$

The experimental internuclear distance of the two $H$ atoms, $2 c^{\prime}{ }_{H-H}$, is [23]:

$$
\begin{equation*}
2 c_{H-H}^{\prime}=1.55 \pm 0.01 \times 10^{-10} \mathrm{~m} \tag{13.243}
\end{equation*}
$$

which matches Eq. (13.236) very well. The experimental angle between the $O-H$ bonds is [23]:

$$
\begin{equation*}
\theta=106^{\circ} \tag{13.244}
\end{equation*}
$$

which matches the predicted angle given by Eq. (13.242).
The results of the determination of bond parameters of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{D}_{2} \mathrm{O}$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## HYDROGEN NITRIDE ( $N H$ )

The ammonia molecule can be solved by first considering the solution of the hydrogen and dihydrogen nitride radicals. The former is formed by the reaction of a hydrogen atom and a nitrogen atom:

$$
\begin{equation*}
H+N \rightarrow N H \tag{13.245}
\end{equation*}
$$

The hydrogen nitride radicals, NH and $\mathrm{NH}_{2}$, and ammonia, $\mathrm{NH}_{3}$, can be solved using the same principles as those used to solve OH and $\mathrm{H}_{2} \mathrm{O}$.

## FORCE BALANCE OF $N H$

NH comprises two spin-paired electrons in a chemical bond between the nitrogen atom and the hydrogen atom such that two electrons on $N$ remain unpaired. The $N H$ radical molecular orbital (MO) is determined by considering properties of the binding atoms and the boundary constraints. The prolate spheroidal $\mathrm{H}_{2} \mathrm{MO}$ developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules section satisfies the boundary constraints; thus, the $H$-atom electron forms a $H_{2}$-type ellipsoidal MO with one of the $N$-atom electrons. The $N$ electron configuration given in the Seven-Electron Atoms section is $1 s^{2} 2 s^{2} 2 p^{3}$, and the orbital arrangement is

$$
\begin{equation*}
2 \mathrm{p} \text { state } \tag{13.246}
\end{equation*}
$$

corresponding to the ground state ${ }^{4} S_{3 / 2}^{0}$. The $N 2 p_{x}$ electron combines with the $H 1 s$ electron to form a molecular orbital. The proton of the $H$ atom is along the internuclear axis. Due to symmetry, the other $N$ electrons are equivalent to point charges at the origin. (See Eqs. (19-38) of Appendix II.) Thus, the energies in the $N H$ MO involve only the $N 2 p_{x}$ and $H 1 s$ electrons and the change in the magnetic energy of the $N 2 p_{x}$ electron with the other $N$ electrons (Eq. (13.305)) with the formation of the NH MO. The forces are determined by these energies.

As in the case of $\mathrm{H}_{2}$, the MO is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $N$ atom for distances shorter than the radius of the $2 p$ shell. Thus, the MO surface comprises a prolate spheroid at the $H$ proton that is continuous with the $2 p$ shell at the $N$ atom whose nucleus serves as the other focus. The energy of the prolate spheroid is matched to that of the $N 2 p$ shell. As in the case with OH , the linear combination of the $H_{2}$-type ellipsoidal MO with the $N 2 p$ AO must involve a $25 \%$ contribution from the $H_{2}$-type ellipsoidal MO to the $N 2 p$ atomic orbital (AO) in order to match potential, kinetic, and orbital energy relationships. Thus, the NH MO must comprise $75 \%$ of a $H_{2}$-type ellipsoidal MO and a nitrogen AO :

$$
\begin{equation*}
1 \mathrm{~N} 2 p_{x} \mathrm{AO}+0.75 \mathrm{H}_{2} \mathrm{MO} \rightarrow \mathrm{NH} \mathrm{MO} \tag{13.247}
\end{equation*}
$$

The force balance of the $N H$ MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.247) and the energy matching condition between the hydrogen and nitrogen components of the MO.

Similar to the OH case given by Eq. (13.59), the $\mathrm{H}_{2}$-type ellipsoidal MO comprises $75 \%$ of the NH MO ; so, the electron charge density in Eq. (11.65) is given by $-0.75 e$. Based on the condition that the electron MO is an equipotential energy surface, Eq. (11.79) gives the ellipsoidal parameter $c^{\prime}$ in terms of the central force of the foci, the electron angular momentum, and the ellipsoidal parameter $a$. To meet the equipotential condition of the union of the $H_{2}$-type-ellipsoidal-MO and the $N \mathrm{AO}$, the force constant used to determine the ellipsoidal parameter $c^{\prime}$ is normalized by the ratio of the ionization energy of $N 14.53414 \mathrm{eV}$ [6] and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). This normalizes the force to match that of the Coulombic force alone to meet the force matching condition of the $N H \mathrm{MO}$ under the influence of the proton and the $N$ nucleus. Thus, $k^{\prime}$ of Eq. (11.79) to determine $c^{\prime}$ is

$$
\begin{equation*}
k^{\prime}=\frac{(0.75) 2 e^{2}}{4 \pi \varepsilon_{0} \frac{14.53414}{13.605804}}=(0.936127) \frac{(0.75) 2 e^{2}}{4 \pi \varepsilon_{0}} \tag{13.248}
\end{equation*}
$$

$L$ for the electron equals $\hbar$; thus, the distance from the origin of the $N H \mathrm{MO}$ to each focus $c^{\prime}$ is given by Eqs. (11.79) and (13.248):

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 1.5 a(0.936127)}}=\sqrt{\frac{2 a a_{0}}{3(0.936127)}}=\sqrt{0.712154 a a_{0}} \tag{13.249}
\end{equation*}
$$

The internuclear distance from Eq. (13.249) is

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{0.712154 a a_{0}} \tag{13.250}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal $N H$ MO $b=c$ is given by Eqs. (11.80) and (13.62). The eccentricity, $e$, is given by Eq. (13.63). Then, the solution of the semimajor axis $a$ allows for the solution of the other axes of the prolate spheroidal and eccentricity of the NH MO .

The energy of the nitrogen $2 p$ shell is the negative of the ionization energy of the nitrogen atom given by Eq. (10.143). Experimentally, the energy is [6]:

$$
\begin{equation*}
E(2 p \text { shell })=-E(\text { ionization } ; N)=-14.53414 \mathrm{eV} \tag{13.251}
\end{equation*}
$$

Since the prolate spheroidal MO transitions to the $N$ AO, the energy $E$ in Eq. (13.251) adds to that of the $H_{2}$-type ellipsoidal MO to give the total energy of the $N H$ MO. From the energy equation and the relationship between the axes given by Eqs. (13.249-13.250) and (13.62-13.63), the dimensions of the NH MO are solved.

The energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ are the same as those of $O H$ given by Eqs. (13.67-13.73). Similarly to $O H$, the total energy $E_{T}(N H)$ of the $N H$ MO is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $N \mathrm{AO}$ and the $H_{2}$-type ellipsoidal MO that forms the $N H$ MO as given by Eq. (13.247):

$$
\begin{equation*}
E_{T}(N H)=E_{T}+E(2 p \text { shell })=E_{T}-E(\text { ionization } ; N)=-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.53414 \mathrm{eV} \tag{13.252}
\end{equation*}
$$

To match the boundary condition that the total energy of the entire $H_{2}$-type ellipsoidal MO is given by Eqs. (11.212) and (13.75), $E_{T}(N H)$ given by Eq. (13.252) is set equal to Eq. (13.75):

$$
\begin{equation*}
E_{T}(N H)=-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.53414 \mathrm{eV}=-31.63536831 \mathrm{eV} \tag{13.253}
\end{equation*}
$$

From the energy relationship given by Eq. (13.252) and the relationship between the axes given by Eqs. (13.249-13.250) and (13.62-13.63), the dimensions of the $N H$ MO can be solved.

Substitution of Eq. (13.249) into Eq. (13.253) gives:

$$
\begin{equation*}
\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{0.712154 a a_{0}}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{0.712154 a a_{0}}}{a-\sqrt{0.712154 a a_{0}}}-1\right]=e 17.10123 \tag{13.254}
\end{equation*}
$$

The most convenient way to solve Eq. (13.254) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is

$$
\begin{equation*}
a=1.36275 a_{0}=7.21136 \times 10^{-11} \mathrm{~m} \tag{13.255}
\end{equation*}
$$

Substitution of Eq. (13.255) into Eq. (13.249) gives:

$$
\begin{equation*}
c^{\prime}=0.98513 a_{0}=5.21310 \times 10^{-11} \mathrm{~m} \tag{13.256}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.256) by two is:

$$
\begin{equation*}
2 c^{\prime}=1.97027 a_{0}=1.04262 \times 10^{-10} \mathrm{~m} \tag{13.257}
\end{equation*}
$$

The experimental bond distance is [28]:

$$
\begin{equation*}
2 c^{\prime}=1.0362 \times 10^{-10} \mathrm{~m} \tag{13.258}
\end{equation*}
$$

Substitution of Eqs. (13.255-13.256) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=0.94159 a_{0}=4.98270 \times 10^{-11} \mathrm{~m} \tag{13.259}
\end{equation*}
$$

Substitution of Eqs. (13.255-13.256) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.72290 \tag{13.260}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $N$ atom comprise the foci of the $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $N 2 p_{x} \mathrm{AO}$ are given by Eqs. (13.84-13.95). The polar intersection angle $\theta^{\prime}$ is given by:

$$
\begin{equation*}
\theta^{\prime}=\cos ^{-1}\left(\frac{a}{c^{\prime}}\left(\left(a-c^{\prime}\right) \frac{1+\frac{c^{\prime}}{a}}{r_{n}}-1\right)\right) \tag{13.261}
\end{equation*}
$$

where $r_{n}=r_{7}=0.93084 a_{0}$ is the radius of the $N$ atom. Substitution of Eqs. (13.255-13.256) into Eq. (13.86) gives:

$$
\begin{equation*}
\theta^{\prime}=114.61^{\circ} \tag{13.262}
\end{equation*}
$$

Then, the angle $\theta_{N 2 p_{x} A O}$ the radial vector of the $N 2 p_{x}$ AO makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{N 2 p_{x} A O}=180^{\circ}-114.61^{\circ}=65.39^{\circ} \tag{13.263}
\end{equation*}
$$

as shown in Figure 13.5.

Figure 13.5. The cross section of the $N H$ MO showing the axes, angles, and point of intersection of the $H_{2}$-type ellipsoidal MO with the $N 2 p_{x}$ AO. The continuation of the $H_{2}$-type-ellipsoidal-MO basis element beyond the intersection point with the $N 2 p$ shell is shown as dashed since it only serves to solve the energy match with the $N 2 p$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of the intersection point. The actual charge density is shown by the solid lines. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $d_{1}: d_{H_{2} M O}, \theta_{1}: \theta_{N 2 p_{x} A O}$, $d_{2}: d_{N 2 p A O}$, and $R: r_{7}$.

The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{\mathrm{H}_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{7} \sin \theta_{N 2 p_{x} A O}=0.93084 a_{0} \sin \theta_{N 2 p_{x} A O}=b \sin \theta_{H_{2} M O} \tag{13.264}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{H_{2} M O}=\sin ^{-1} \frac{0.93084 a_{0} \sin \theta_{N 2 p_{x} A O}}{b}=\sin ^{-1} \frac{0.93084 a_{0} \sin 65.39^{\circ}}{b} \tag{13.265}
\end{equation*}
$$

with the use of Eq. (13.263). Substitution of Eq. (13.259) into Eq. (13.265) gives:

$$
\begin{equation*}
\theta_{H_{2} M O}=64.00^{\circ} \tag{13.266}
\end{equation*}
$$

Then, the distance $d_{\mathrm{H}_{2} \mathrm{MO}}$ along the internuclear axis from the origin of $\mathrm{H}_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{\mathrm{H}_{2} \mathrm{MO}}=a \cos \theta_{\mathrm{H}_{2} \mathrm{MO}} \tag{13.267}
\end{equation*}
$$

Substitution of Eqs. (13.255) and (13.266) into Eq. (13.267) gives:

$$
\begin{equation*}
d_{\mathrm{H}_{2} M O}=0.59747 a_{0}=3.16166 \times 10^{-11} \mathrm{~m} \tag{13.268}
\end{equation*}
$$

The distance $d_{N 2 p A O}$ along the internuclear axis from the origin of the $N$ atom to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{N 2 p A O}=c^{\prime}-d_{H_{2} M O} \tag{13.269}
\end{equation*}
$$

Substitution of Eqs. (13.79) and (13.93) into Eq. (13.94) gives:

$$
\begin{equation*}
d_{N 2 p A O}=0.38767 a_{0}=2.05144 \times 10^{-11} \mathrm{~m} \tag{13.270}
\end{equation*}
$$

As shown in Eq. (13.247), in addition to the $p$-orbital charge-density modulation, the uniform charge-density in the $p_{x}$ orbital is increased by a factor of 0.25 and the $H$-atom density is decreased by a factor of 0.25 . The internuclear axis of the $N-H$ bond is perpendicular to the bonding $p_{x}$ orbital. Using the orbital composition of $N H$ (Eq. (13.27)), the radii of $N 1 s=0.14605 a_{0}$ (Eq. (10.51)), $N 2 s=0.69385 a_{0}$ (Eq. (10.62)), and $N 2 p=0.93084 a_{0}$ (Eq. (10.142)) shells, and the parameters of the $N H$ MO given by Eqs. (13.3-13.4) and (13.255-13.270), the dimensional diagram and charge-density of the $N H$ MO comprising the linear combination of the $H_{2}$-type ellipsoidal MO and the $N \mathrm{AO}$ according to Eq. (13.247) are shown in Figures 13.5 and 13.6, respectively.

Figure 13.6. $N H \mathrm{MO}$ comprising the superposition of the $H_{2}$-type ellipsoidal MO and the $N 2 p_{x} \mathrm{AO}$ with a relative charge-density of 0.75 to 1.25 ; otherwise, the $N 2 p_{x}$ is the same as that of the nitrogen atom. (A) Side-on, color scale, translucent view of the charge-density of the NH MO . The ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $N 2 p_{x} \mathrm{AO}$, the $N 2 p$ shell, the $N 2 s$ shell, the $N 1 s$ shell, and the nuclei (red not to scale) are shown. (B) Cut-away view showing the inner most $N 1 s$ shell, and moving radially, the $N 2 s$ shell, the $N 2 p$ shell, and the $H_{2}$-type ellipsoidal MO that transitions to the $N 2 p_{x} \mathrm{AO}$.

## ENERGIES OF $N H$

The energies of $N H$ given by the substitution of the semiprincipal axes (Eqs. (13.255-13.256) and (13.259)) into the energy equations (Eqs. (13.67-13.73)) are:

$$
\begin{align*}
& V_{e}=\left(\frac{3}{4}\right) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-37.85748 \mathrm{eV}  \tag{13.271}\\
& V_{p}=\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=13.81113 \mathrm{eV}  \tag{13.272}\\
& T=\left(\frac{3}{4}\right) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=13.89011 \mathrm{eV}  \tag{13.273}\\
& V_{m}=\left(\frac{3}{4}\right) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-6.94505 \mathrm{eV}  \tag{13.274}\\
& E_{T}(N H)=-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.53414 \mathrm{eV}=-31.63544 \mathrm{eV} \tag{13.275}
\end{align*}
$$

where $E_{T}(N H)$ is given by Eq. (13.253) which is reiteratively matched to Eq. (13.75) within five-significant-figure round-off error.

## VIBRATION AND ROTATION OF $N H$

The vibrational energy of $N H$ may be solved in the same manner as that of $O H$. From Eqs. (13.102-13.106) with the substitution of the $N H$ parameters, the angular frequency of the oscillation is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{8 \pi \varepsilon_{0} b^{3}}-\frac{e^{2}}{8 \pi \varepsilon_{0}\left(2 c^{\prime}\right)^{3}}}{\mu}}=\sqrt{\left.\frac{0.75 e^{2}}{\frac{8 \pi \varepsilon_{0}\left(0.94159 \mathrm{a}_{0}\right)^{3}}{}-\frac{e^{2}}{\frac{14}{15} m_{p}}}=6.18700 \times 10^{14} \mathrm{rad} / \mathrm{s} . .97027 a_{0}\right)^{3}}=\sqrt{\frac{1}{2}}= \tag{13.276}
\end{equation*}
$$

where $b$ is given by Eq. (13.259), $2 c^{\prime}$ is given by Eq. (13.257), and the reduced mass of ${ }^{14} \mathrm{NH}$ is given by:

$$
\begin{equation*}
\mu_{1^{4} \mathrm{NH}}=\frac{m_{1} m_{2}}{m_{1}+m_{2}}=\frac{(1)(14)}{1+14} m_{p} \tag{13.277}
\end{equation*}
$$

where $m_{p}$ is the proton mass. Thus, during bond formation, the perturbation of the orbit determined by an inverse-squared force results in simple harmonic oscillatory motion of the orbit, and the corresponding frequency, $\omega(0)$, for ${ }^{14} \mathrm{NH}$ given by Eqs. (11.136), (11.148), and (13.276) is

$$
\begin{equation*}
\omega(0)=\sqrt{\frac{k(0)}{\mu}}=\sqrt{\frac{597.59 \mathrm{Nm}^{-1}}{\mu}}=6.18700 \times 10^{14} \mathrm{radians} / \mathrm{s} \tag{13.278}
\end{equation*}
$$

where the reduced nuclear mass of ${ }^{14} \mathrm{NH}$ is given by Eq. (13.277) and the spring constant, $k(0)$, given by Eqs. (11.136) and (13.276) is:

$$
\begin{equation*}
k(0)=597.59 \mathrm{Nm}^{-1} \tag{13.279}
\end{equation*}
$$

The ${ }^{14} \mathrm{NH}$ transition-state vibrational energy, $E_{v i b}(0)$, given by Planck's equation (Eq. (11.127)) is:

$$
\begin{equation*}
E_{v i b}(0)=\hbar \omega=\hbar 6.18700 \times 10^{14} \mathrm{rad} / \mathrm{s}=0.407239 \mathrm{eV}=3284.58 \mathrm{~cm}^{-1} \tag{13.280}
\end{equation*}
$$

$\omega_{e}$, from the experimental curve fit of the vibrational energies of ${ }^{14} \mathrm{NH}$ is [28]:

$$
\begin{equation*}
\omega_{e}=3282.3 \mathrm{~cm}^{-1} \tag{13.281}
\end{equation*}
$$

Using Eqs. (13.112-13.118) with $E_{v i b}(0)$ given by Eq. (13.280) and $D_{0}$ given by Eq. (13.311), the ${ }^{14} \mathrm{NH} v=1 \rightarrow v=0$ vibrational energy, $E_{v i b}(1)$ is:

$$
\begin{equation*}
E_{v i b}(1)=0.38581 \mathrm{eV} \quad\left(3111.84 \mathrm{~cm}^{-1}\right) \tag{13.282}
\end{equation*}
$$

The experimental vibrational energy of ${ }^{14} \mathrm{NH}$ using $\omega_{e}$ and $\omega_{e} x_{e}$ [28] according to K\&P [15] is:

$$
\begin{equation*}
E_{v i b}(1)=0.38752 \mathrm{eV} \quad\left(3125.5 \mathrm{~cm}^{-1}\right) \tag{13.283}
\end{equation*}
$$

Using Eq. (13.113) with $E_{v i b}(1)$ given by Eq. (13.282) and $D_{0}$ given by Eq. (13.311), the anharmonic perturbation term, $\omega_{0} x_{0}$, of ${ }^{14} \mathrm{NH}$ is:

$$
\begin{equation*}
\omega_{0} x_{0}=86.37 \mathrm{~cm}^{-1} \tag{13.284}
\end{equation*}
$$

The experimental anharmonic perturbation term, $\omega_{0} x_{0}$, of ${ }^{14} \mathrm{NH}$ [28] is:

$$
\begin{equation*}
\omega_{0} x_{0}=78.4 \mathrm{~cm}^{-1} \tag{13.285}
\end{equation*}
$$

The vibrational energies of successive states are given by Eqs. (13.280), (13.112), and (13.284).
Using $b$ given by Eq. (13.259), $2 c^{\prime}$ given by Eq. (13.257), $D_{0}$ given by Eq. (13.314), and the reduced nuclear mass of ${ }^{14} N D$ given by

$$
\begin{equation*}
\mu_{1^{4} N D}=\frac{m_{1} m_{2}}{m_{1}+m_{2}}=\frac{(2)(14)}{2+14} m_{p} \tag{13.286}
\end{equation*}
$$

where $m_{p}$ is the proton mass, the corresponding parameters for deuterium nitride ${ }^{14} N D$ (Eqs. (13.102-13.121)) are:

$$
\begin{align*}
& \omega(0)=\sqrt{\frac{k(0)}{\mu}}=\sqrt{\frac{597.59 \mathrm{Nm}^{-1}}{\mu}}=4.51835 \times 10^{14} \text { radians } / \mathrm{s}  \tag{13.287}\\
& k(0)=579.59 \mathrm{Nm}^{-1}  \tag{13.288}\\
& E_{\text {vib }}(0)=\hbar \omega=\hbar 4.51835 \times 10^{14} \mathrm{rad} / \mathrm{s}=0.29741 \mathrm{eV}=2398.72 \mathrm{~cm}^{-1}  \tag{13.289}\\
& E_{\text {vib }}(1)=0.28710 \mathrm{eV} \quad\left(2305.35 \mathrm{~cm}^{-1}\right)  \tag{13.290}\\
& \omega_{0} x_{0}=47.40 \mathrm{~cm}^{-1} \tag{13.291}
\end{align*}
$$

$\omega_{e}$, from the experimental curve fit of the vibrational energies of ${ }^{14} N D$ is [28]:

$$
\begin{equation*}
\omega_{e}=2398 \mathrm{~cm}^{-1} \tag{13.292}
\end{equation*}
$$

The experimental vibrational energy of ${ }^{14} N D$ using $\omega_{e}$ and $\omega_{e} x_{e}$ [28] according to K\&P [15] is:

$$
\begin{equation*}
E_{v i b}(1)=0.2869 \mathrm{eV} \quad\left(2314 \mathrm{~cm}^{-1}\right) \tag{13.293}
\end{equation*}
$$

and the experimental anharmonic perturbation term, $\omega_{0} x_{0}$, of ${ }^{14} N D$ [28] is:

$$
\begin{equation*}
\omega_{0} x_{0}=42 \mathrm{~cm}^{-1} \tag{13.294}
\end{equation*}
$$

which match the predictions given by Eqs. (13.289), (13.290) and (13.291), respectively.
Using Eqs. (13.133-13.134) and the internuclear distance, $r=2 c^{\prime}$, and reduced mass of ${ }^{14} \mathrm{NH}$ given by Eqs. (13.257) and (13.277), respectively, the corresponding $B_{e}$ is:

$$
\begin{equation*}
B_{e}=16.495 \mathrm{~cm}^{-1} \tag{13.295}
\end{equation*}
$$

The experimental $B_{e}$ rotational parameter of ${ }^{14} \mathrm{NH}$ is [28]:

$$
\begin{equation*}
B_{e}=16.6993 \mathrm{~cm}^{-1} \tag{13.296}
\end{equation*}
$$

Using the internuclear distance, $r=2 c^{\prime}$, and reduced mass of ${ }^{14} N D$ given by Eqs. (13.257) and (13.286), respectively, the corresponding $B_{e}$ is:

$$
\begin{equation*}
B_{e}=8.797 \mathrm{~cm}^{-1} \tag{13.297}
\end{equation*}
$$

The experimental $B_{e}$ rotational parameter of ${ }^{14} N D$ is [28]:

$$
\begin{equation*}
B_{e}=8.7913 \mathrm{~cm}^{-1} \tag{13.298}
\end{equation*}
$$

## THE DOPPLER ENERGY TERMS OF ${ }^{14} \mathrm{NH}$ AND ${ }^{14} \mathrm{ND}$

The equations of the radiation reaction force of hydrogen and deuterium nitride are the same as those of the corresponding hydroxyl radicals with the substitution of the hydrogen and deuterium nitride parameters. Using Eqs. (11.136) and (13.14013.141), the angular frequency of the reentrant oscillation in the transition state is

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=3.91850 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{13.299}
\end{equation*}
$$

where $b$ is given by Eq. (13.259). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 3.91850 \times 10^{16} \mathrm{rad} / \mathrm{s}=25.79224 \mathrm{eV} \tag{13.300}
\end{equation*}
$$

In Eq. (11.181), substitution of the total energy of $N H, E_{T}(N H)$, (Eq. (13.253)) for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.300) for $\bar{E}_{K}$ gives the Doppler energy of the electrons for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h v} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-31.63537 \mathrm{eV} \sqrt{\frac{2 e(25.79224 \mathrm{eV})}{m_{e} c^{2}}}=-0.31785 \mathrm{eV} \tag{13.301}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of $N H$ due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.301) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of NH . Using the experimental ${ }^{14} \mathrm{NH} \omega_{e}$ of $3282.3 \mathrm{~cm}^{-1}(0.40696 \mathrm{eV})$ [28] $\bar{E}_{\text {osc }}\left({ }^{14} \mathrm{NH}\right)$ is:

$$
\begin{align*}
& \bar{E}_{\text {osc }}\left({ }^{14} N H\right)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.302}\\
& \bar{E}_{\text {osc }}\left({ }^{14} N H\right)=-0.31785 \mathrm{eV}+\frac{1}{2}(0.40696 \mathrm{eV})=-0.11437 \mathrm{eV} \tag{13.303}
\end{align*}
$$

Using Eqs. (13.301) and the experimental ${ }^{14} N D \omega_{e}$ of $2398 \mathrm{~cm}^{-1}(0.29732 \mathrm{eV})$ [28] $\bar{E}_{\text {osc }}\left({ }^{14} \mathrm{ND}\right)$ is:

$$
\begin{equation*}
\bar{E}_{\text {osc }}\left({ }^{14} N D\right)=-0.31785 \mathrm{eV}+\frac{1}{2}(0.29732 \mathrm{eV})=-0.16919 \mathrm{eV} \tag{13.304}
\end{equation*}
$$

## TOTAL AND BOND ENERGIES OF ${ }^{14} \mathrm{NH}$ AND ${ }^{14} \mathrm{ND}$

$E_{T+o s c}(N H)$, the total energy of the ${ }^{14} \mathrm{NH}$ radical including the Doppler term, is given by the sum of $E_{T}(N H)$ (Eq. (13.253)) and $\bar{E}_{\text {osc }}\left({ }^{14} N H\right)$ given by Eq. (13.303):

$$
\begin{align*}
E_{T+o s c}(N H) & =V_{e}+T+V_{m}+V_{p}+E(2 p \text { shell })+\bar{E}_{\text {osc }}\left({ }^{14} N H\right)  \tag{13.305}\\
& =E_{T}(N H)+\bar{E}_{\text {osc }}\left({ }^{14} N H\right) \\
E_{T+o s c}(N H) & =\left\{\frac{-e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.53414 e V\right\}\left[\sqrt{\frac{2 \hbar \sqrt{\frac{\frac{3}{4} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}}{m_{e} c^{2}}}\right]+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.306}\\
& =-31.63537 \mathrm{eV}-0.31785 \mathrm{eV}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}
\end{align*}
$$

From Eqs. (13.302-13.303) and (13.305-13.306), the total energy of ${ }^{14} \mathrm{NH}$ is:

$$
\begin{align*}
E_{T+o s c}(N H) & =-31.63537 \mathrm{eV}+\bar{E}_{\text {osc }}\left({ }^{14} \mathrm{NH}\right) \\
& =-31.63537 \mathrm{eV}-0.31785 \mathrm{eV}+\frac{1}{2}(0.40696 \mathrm{eV})  \tag{13.307}\\
& =-31.74974 \mathrm{eV}
\end{align*}
$$

where the experimental $\omega_{e}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term. $E_{T+o s c}(N D)$, the total energy of ${ }^{14} N D$ including the Doppler term, is given by the sum of $E_{T}(N D)=E_{T}(N H)$ (Eq. (13.253)) and $\bar{E}_{\text {osc }}\left({ }^{14} N D\right)$ given by Eq. (13.304):

$$
\begin{align*}
E_{T+o s c}(N D) & =-31.63537 \mathrm{eV}+\bar{E}_{\text {osc }}\left({ }^{14} \mathrm{ND}\right) \\
& =-31.63537 \mathrm{eV}-0.31785 \mathrm{eV}+\frac{1}{2}(0.29732 \mathrm{eV})  \tag{13.308}\\
& =-31.80456 \mathrm{eV}
\end{align*}
$$

where the experimental $\omega_{e}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term. The dissociation of the bond of the hydrogen nitride forms a free hydrogen atom with one unpaired electron and a nitrogen atom with three unpaired electrons as shown in Eq. (13.246). The $p_{x}$ and $p_{y}$ fields cancel and the magnetic energy (Eq. (7.46)) with $r_{7}=0.93084 a_{0}$ is subtracted due to the one component of $E_{\operatorname{mag}}$ given by Eq. (10.137):

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(0.93084 a_{0}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.93084 a_{0}\right)^{3}}=0.14185 \mathrm{eV} \tag{13.309}
\end{equation*}
$$

The corresponding bond dissociation energy, $E_{D}$, is given by the sum of the total energies of the nitrogen atom and the corresponding hydrogen atom minus the sum of $E_{T+o s c}(N H)$ and $E$ (magnetic) :

$$
\begin{equation*}
E_{D}=E\left({ }^{14} N\right)+E(H)-E_{T+o s c}(N H)-E(\text { magnetic }) \tag{13.310}
\end{equation*}
$$

$E\left({ }^{14} N\right)$ is given by Eq. (13.251), $E_{D}(H)$ is given by Eq. (13.154), and $E_{D}(D)$ is given by Eq. (13.155). The ${ }^{14} N H$ bond dissociation energy, $E_{D}\left({ }^{14} \mathrm{NH}\right)$, is given by Eqs. (13.154), (13.251), (13.307), and (13.309-13.310):

$$
\begin{align*}
E_{D}\left({ }^{14} N H\right) & =-(14.53414 \mathrm{eV}+13.59844 \mathrm{eV})-\left(E(\text { magnetic })+E_{T+\text { osc }}(N H)\right) \\
& =-28.13258 \mathrm{eV}-(0.14185-31.74974 \mathrm{eV})  \tag{13.311}\\
& =3.47530 \mathrm{eV}
\end{align*}
$$

The experimental ${ }^{14} \mathrm{NH}$ bond dissociation energy from Ref. [29] and Ref. [30] is:

$$
\begin{align*}
& E_{D}\left({ }^{14} \mathrm{NH}\right)=3.42 \mathrm{eV}  \tag{13.312}\\
& E_{D}\left({ }^{14} \mathrm{NH}\right) \leq 3.47 \mathrm{eV} \tag{13.313}
\end{align*}
$$

The ${ }^{14} N D$ bond dissociation energy, $E_{D}\left({ }^{14} N D\right)$, is given by Eqs. (13.155), (13.251), (13.308), and (13.309-13.310):

$$
\begin{align*}
E_{D}\left({ }^{14} N D\right) & =-(14.53414 \mathrm{eV}+13.603 \mathrm{eV})-\left(E(\text { magnetic })+E_{T+\text { osc }}(N D)\right) \\
& =-28.13714 \mathrm{eV}-(0.14185-31.80456 \mathrm{eV})  \tag{13.314}\\
& =3.5256 \mathrm{eV}
\end{align*}
$$

The experimental ${ }^{14} N D$ bond dissociation energy from Ref. [31] and Ref. [30] is:

$$
\begin{align*}
& E_{D_{298}}\left({ }^{14} \mathrm{ND}\right) \leq 339 \mathrm{~kJ} / \mathrm{mol}=3.513 \mathrm{eV}  \tag{13.315}\\
& E_{D}\left({ }^{14} \mathrm{ND}\right) \leq 3.54 \mathrm{eV} \tag{13.316}
\end{align*}
$$

The results of the determination of bond parameters of $N H$ and $N D$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## DIHYDROGEN NITRIDE ( $\mathrm{NH}_{2}$ )

The dihydrogen nitride radical $\mathrm{NH}_{2}$ is formed by the reaction of a hydrogen atom with a hydrogen nitride radical:

$$
\begin{equation*}
\mathrm{NH}+\mathrm{H} \rightarrow \mathrm{NH}_{2} \tag{13.317}
\end{equation*}
$$

$\mathrm{NH}_{2}$ can be solved using the same principles as those used to solve $\mathrm{H}_{2} \mathrm{O}$. Two diatomic molecular orbitals (MOs) developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section serve as basis functions in a linear combination with two nitrogen atomic orbitals (AOs) to form the MO of $\mathrm{NH}_{2}$. The solution is very similar to that of NH except that there are two NH bonds in $\mathrm{NH}_{2}$.

## FORCE BALANCE OF $\mathrm{NH}_{2}$

$\mathrm{NH}_{2}$ comprises two chemical bonds between nitrogen and hydrogen. Each $\mathrm{N}-\mathrm{H}$ bond comprises two spin-paired electrons with one from an initially unpaired electron of the nitrogen atom and the other from the hydrogen atom. Each $H$-atom electron forms a $H_{2}$-type ellipsoidal MO with one of the initially unpaired $N$-atom electrons, $2 p_{x}$ or $2 p_{y}$, such that the proton and the $N$ nucleus serve as the foci. The initial $N$ electron configuration given in the Seven-Electron Atoms section is $1 s^{2} 2 s^{2} 2 p^{3}$, and the orbital arrangement is given by Eqs. (10.134) and (13.246). The radius and the energy of the $N 2 p$ shell are unchanged with bond formation. The central paramagnetic force due to spin of each $N-H$ bond is provided by the spin-pairing force of the $\mathrm{NH}_{2}$ MO that has the symmetry of an $s$ orbital that superimposes with the $N 2 p$ orbitals such that the corresponding angular momenta are unchanged.

As in the case of $H_{2}$, each of two $N-H$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $N$ atom for distances shorter than the radius of the $2 p$ shell since it is energetically unfavorable. Thus, the MO surface comprises a prolate spheroid at each $H$ proton that is continuous with the $2 p$ shell at the $N$ atom. The energies in the $\mathrm{NH}_{2}$ MO involve only each $\mathrm{N} 2 p$ and each $H 1 s$ electron with the formation of each $N-H$ bond. The sum of the energies of the prolate spheroids is matched to that of the $2 p$ shell. The forces are determined by these energies. As in the case of NH , the linear combination of each $\mathrm{H}_{2}$-type ellipsoidal MO with each $\mathrm{N} 2 p \mathrm{AO}$ must involve a $25 \%$ contribution from the $H_{2}$-type ellipsoidal MO to the $N 2 p$ AO in order to match potential, kinetic, and orbital energy relationships. Thus, the $\mathrm{NH}_{2}$ MO must comprise two $\mathrm{N}-\mathrm{H}$ bonds with each comprising $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO $(1 / 2+25 \%)$ and a nitrogen AO:

$$
\begin{equation*}
\left[1 \mathrm{~N} 2 p_{x} \mathrm{AO}+0.75 \mathrm{H}_{2} \mathrm{MO}\right]+\left[1 \mathrm{~N} 2 p_{y} \mathrm{AO}+0.75 \mathrm{H}_{2} \mathrm{MO}\right] \rightarrow \mathrm{NH}_{2} \mathrm{MO} \tag{13.318}
\end{equation*}
$$

The force constant $k^{\prime}$ of each $\mathrm{H}_{2}$-type-ellipsoidal-MO component of the $\mathrm{NH}_{2} \mathrm{MO}$ is given by Eq. (13.248). The distance from the origin of each $N-H$-bond MO to each focus $c^{\prime}$ is given by Eq. (13.249). The internuclear distance is given by Eq. (13.250). The length of the semiminor axis of the prolate spheroidal $N-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $N-H$-bond MO. Since each of the two prolate spheroidal $N-H$-bond MOs comprises a $H_{2}$-type-ellipsoidal MO that transitions to the $N$ AO, the energy $E$ in Eq. (13.251) adds to that of the two corresponding $\mathrm{H}_{2}$-type ellipsoidal MOs to give the total energy of the $\mathrm{NH}_{2} \mathrm{MO}$. From the energy equation and the relationship between the axes, the dimensions of the $\mathrm{NH}_{2} \mathrm{MO}$ are solved.

The energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ are twice those of $O H$ and $N H$ given by Eqs. (13.67-13.73) and equal to those of $\mathrm{H}_{2} \mathrm{O}$ given by Eqs. (13.172-13.178). Similarly to $\mathrm{H}_{2} \mathrm{O}$, since each prolate spheroidal $\mathrm{H}_{2}$-type MO transitions to the $N \mathrm{AO}$ and the energy of the $N 2 p$ shell must remain constant and equal to the negative of the ionization energy given by Eq. (13.251), the total energy $E_{T}\left(\mathrm{NH}_{2}\right)$ of the $\mathrm{NH}_{2} \mathrm{MO}$ is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the NAO and the two $\mathrm{H}_{2}$-type ellipsoidal MOs that forms the $\mathrm{NH}_{2} \mathrm{MO}$ as given by Eq. (13.318):

$$
\begin{align*}
E_{T}\left(N H_{2}\right) & =E_{T}+E(2 p \text { shell })=E_{T}-E(\text { ionization } ; N) \\
& =-\frac{e^{2}}{4 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.53414 \mathrm{eV} \tag{13.319}
\end{align*}
$$

The two hydrogen atoms and the nitrogen atom can achieve an energy minimum as a linear combination of two $H_{2}$-type ellipsoidal MOs each having the proton and the nitrogen nucleus as the foci. Each $N-H$-bond MO comprises the same $N 2 p$ shell of constant energy given by Eq. (13.251). Thus, the energy of the $\mathrm{NH}_{2} \mathrm{MO}$ is also given by the sum of that of the two $H_{2}$-type ellipsoidal MOs given by Eq. (11.212) minus the energy of the redundant nitrogen atom of the linear combination given by Eq. (13.251):

$$
\begin{align*}
E_{T}\left(2 H_{2}-N\right) & =-2 \frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}\left[\left(2 \sqrt{2}-\sqrt{2}+\frac{\sqrt{2}}{2}\right) \ln \frac{\sqrt{2}+1}{\sqrt{2}-1}-\sqrt{2}\right]-E(2 p \text { shell })  \tag{13.320}\\
& =2(-31.63536831 \mathrm{eV})-(-14.53414 \mathrm{eV})=-48.73660 \mathrm{eV}
\end{align*}
$$

$E_{T}\left(\mathrm{NH}_{2}\right)$ given by Eq. (13.319) is set equal to two times the energy of the $H_{2}$-type ellipsoidal MO minus the energy of the $N 2 p$ shell given by Eq. (13.320):

$$
\begin{equation*}
E_{T}\left(N H_{2}\right)=-\frac{e^{2}}{4 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.53414 \mathrm{eV}=-48.73660 \mathrm{eV} \tag{13.321}
\end{equation*}
$$

From the energy relationship given by Eq. (13.321) and the relationship between the axes given by Eqs. (13.248-13.250) and (13.62-13.63), the dimensions of the $\mathrm{NH}_{2}$ MO can be solved.

Substitution of Eq. (13.249) into Eq. (13.321) gives:

$$
\begin{equation*}
\frac{e^{2}}{4 \pi \varepsilon_{0} \sqrt{0.712154 a a_{0}}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{0.712154 a a_{0}}}{a-\sqrt{0.712154 a a_{0}}}-1\right]=e 34.20246 \tag{13.322}
\end{equation*}
$$

The most convenient way to solve Eq. (13.322) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is

$$
\begin{equation*}
a=1.36276 a_{0}=7.21141 \times 10^{-11} \mathrm{~m} \tag{13.323}
\end{equation*}
$$

Substitution of Eq. (13.323) into Eq. (13.249) gives:

$$
\begin{equation*}
c^{\prime}=0.98514 a_{0}=5.21312 \times 10^{-11} \mathrm{~m} \tag{13.324}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.324) by two is:

$$
\begin{equation*}
2 c^{\prime}=1.97027 a_{0}=1.04262 \times 10^{-10} \mathrm{~m} \tag{13.325}
\end{equation*}
$$

The experimental bond distance is [32]:

$$
\begin{equation*}
2 c^{\prime}=1.024 \times 10^{-10} \mathrm{~m} \tag{13.326}
\end{equation*}
$$

Substitution of Eqs. (13.323-13.324) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=0.94160 a_{0}=4.98276 \times 10^{-11} \mathrm{~m} \tag{13.327}
\end{equation*}
$$

Substitution of Eqs. (13.323-13.324) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.72290 \tag{13.328}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $N$ atom comprise the foci of the $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of each $H_{2}$-type ellipsoidal MO and the $N 2 p_{x}$ AO or $N 2 p_{y}$ AO are given by Eqs. (13.84-13.95) and (13.261-13.270). Using Eqs. (13.323-13.325) and (13.327-13.328), the polar intersection angle $\theta^{\prime}$ given by Eq. (13.261) with $r_{n}=r_{7}=0.93084 a_{0}$ is

$$
\begin{equation*}
\theta^{\prime}=114.61^{\circ} \tag{13.329}
\end{equation*}
$$

Then, the angle $\theta_{N 2 p A O}$ the radial vector of the $N 2 p_{x} \mathrm{AO}$ or $N 2 p_{y} \mathrm{AO}$ makes with the internuclear axis is

$$
\begin{equation*}
\theta_{N 2 p A O}=180^{\circ}-114.61^{\circ}=65.39^{\circ} \tag{13.330}
\end{equation*}
$$

as shown in Figure 13.5. The parametric angle $\theta_{\mathrm{H}_{2} M O}$ given by Eqs. (13.264-13.265), (13.327), and (13.330) is:

$$
\begin{equation*}
\theta_{\mathrm{H}_{2} M O}=64.00^{\circ} \tag{13.331}
\end{equation*}
$$

Then, the distance $d_{H_{2} M O}$ along the internuclear axis from the origin of $H_{2}$-type ellipsoidal MO to the point of intersection of the orbitals given by Eqs. (13.267), (13.323), and (13.331) is:

$$
\begin{equation*}
d_{H_{2} M O}=0.59748 a_{0}=3.16175 \times 10^{-11} \mathrm{~m} \tag{13.332}
\end{equation*}
$$

The distance $d_{N 2 p A O}$ along the internuclear axis from the origin of the $N$ atom to the point of intersection of the orbitals given by Eqs. (13.269), (13.324), and (13.332) is:

$$
\begin{equation*}
d_{N 2 p A O}=0.38765 a_{0}=2.05137 \times 10^{-11} \mathrm{~m} \tag{13.333}
\end{equation*}
$$

As shown in Eq. (13.318), in addition to the $p$-orbital charge-density modulation, the uniform charge-density in the $p_{x}$ and $p_{y}$ orbitals is increased by a factor of 0.25 and the $H$ atoms are each decreased by a factor of 0.25 . Using the orbital composition of $\mathrm{NH}_{2}$ (Eq. (13.318)), the radii of $N 1 s=0.14605 a_{0}$ (Eq. (10.51)), $N 2 s=0.69385 a_{0}$ (Eq. (10.62)), and $N 2 p=0.93084 a_{0}$ (Eq. (10.142)) shells, and the parameters of the $\mathrm{NH}_{2}$ MO given by Eqs. (13.3-13.4) and (13.323-13.333), the charge-density of the $\mathrm{NH}_{2}$ MO comprising the linear combination of two $\mathrm{N}-\mathrm{H}$-bond MOs ( NH -type ellipsoidal MOs given in the Energies of $N H$ section) according to Eq. (13.318) is shown in Figure 13.7. Each $N-H$-bond MO comprises a $H_{2}$-type ellipsoidal MO and an $N 2 p$ AO having the dimensional diagram shown in Figure 13.5.

Figure 13.7. $\mathrm{NH}_{2} \mathrm{MO}$ comprising the linear combination of two $N-H$-bond MOs. Each $N-H$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and the $N 2 p_{x} \mathrm{AO}$ or the $N 2 p_{y} \mathrm{AO}$ with a relative charge-density of 0.75 to 1.25 ; otherwise, the $N 2 p$ orbitals are the same as those of the nitrogen atom. The internuclear axis of one $N-H$ bond is perpendicular to the bonding $p_{x}$ orbital, and the internuclear axis of the other $N-H$ bond is perpendicular to the bonding $p_{y}$ orbital. (A) Color scale, translucent view of the charge-density of the $\mathrm{NH}_{2} \mathrm{MO}$ from the top. For each $\mathrm{N}-\mathrm{H}$ bond, the ellipsoidal surface of each $H_{2}$-type ellipsoidal MO transitions to a $N 2 p$ AO. The $N 2 p$ shell, the $N 2 s$ shell, the $N 1 s$ shell, and the nuclei (red, not to scale) are shown. (B) Cut-away view showing the inner most $N 1 s$ shell, and moving radially, the $N 2 s$ shell, the $N 2 p$ shell, and the $H_{2}$-type ellipsoidal MO that transitions to a $N 2 p$ AO for each $N-H$ bond. Bisector current not shown.

## ENERGIES OF $\mathrm{NH}_{2}$

The energies of $\mathrm{NH}_{2}$ given by the substitution of the semiprincipal axes ((Eqs. (13.323-13.325) and (13.327)) into the energy equations (Eqs. (13.172-13.176)) are:

$$
\begin{align*}
& V_{e}=\left(\frac{3}{2}\right) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-75.71422 \mathrm{eV}  \tag{13.334}\\
& V_{p}=2 \frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=27.62216 \mathrm{eV}  \tag{13.335}\\
& T=\left(\frac{3}{2}\right) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=27.77974 \mathrm{eV}  \tag{13.336}\\
& V_{m}=\left(\frac{3}{2}\right) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-13.88987 \mathrm{eV}  \tag{13.337}\\
& E_{T}\left(N H_{2}\right)=-\frac{e^{2}}{4 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.53414 \mathrm{eV}=-48.73633 \mathrm{eV} \tag{13.338}
\end{align*}
$$

where $E_{T}\left(\mathrm{NH}_{2}\right)$ is given by Eq. (13.319) which is reiteratively matched to Eq. (13.320) within five-significant-figure round-off error.

## VIBRATION OF $\mathrm{NH}_{2}$

The vibrational energy levels of $\mathrm{NH}_{2}$ may be solved as two equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [2] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERM OF $\mathrm{NH}_{2}$

The radiation reaction force in the case of the vibration of $\mathrm{NH}_{2}$ in the transition state corresponds to the Doppler energy, $E_{D}$, given by Eq. (11.181) and Eqs. (13.22) and (13.144) that is dependent on the motion of the electrons and the nuclei. The kinetic energy of the transient vibration is derived from the corresponding central forces. The equations of the radiation reaction force of dihydrogen and dideuterium nitride are the same as those of the corresponding water molecules with the substitution of the dihydrogen and dideuterium nitride parameters. Using Eqs. (11.136) and (13.207-13.209), the angular frequency of the reentrant oscillation in the transition state is

$$
\begin{equation*}
\omega=\sqrt{\frac{\left(\frac{3}{2}\right) \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=5.54150 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{13.339}
\end{equation*}
$$

where $b$ is given by Eq. (13.327). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 5.54150 \times 10^{16} \mathrm{rad} / \mathrm{s}=36.47512 \mathrm{eV} \tag{13.340}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each $H_{2}$-type MO, for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.340) for $\bar{E}_{K}$ gives the Doppler energy of the electrons for the reentrant orbit:

$$
\begin{aligned}
\bar{E}_{D} & \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}} \\
& =-31.63537 \mathrm{eV} \sqrt{\frac{2 e(36.47512 \mathrm{eV})}{m_{e} c^{2}}} \\
& =-0.37798 \mathrm{eV}
\end{aligned}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of $\mathrm{NH}_{2}$ due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.341) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of $\mathrm{NH}_{2}$. Using the experimental ${ }^{14} \mathrm{NH}_{2}$ vibrational energy of $E_{v i b}=3301.110 \mathrm{~cm}^{-1}=0.40929 \mathrm{eV}$ [33] gives:

$$
\begin{align*}
\bar{E}_{o s c}^{\prime} & =\bar{E}_{D}+\bar{E}_{\text {Kvib }}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.342}\\
\bar{E}_{\text {osc }}^{\prime} & =-0.37798 \mathrm{eV}+\frac{1}{2}(0.40929 \mathrm{eV})  \tag{13.343}\\
& =-0.17334 \mathrm{eV}
\end{align*}
$$

per bond. As in the case for $\mathrm{H}_{2} \mathrm{O}$, the reentrant orbit for the binding of a hydrogen atom to a NH radical causes the bonds to oscillate by increasing and decreasing in length along the two $N-H$ bonds at a relative phase angle of $180^{\circ}$. Since the vibration and reentrant oscillation is along two bonds for the asymmetrical stretch $\left(v_{3}\right), \bar{E}_{\text {osc }}$ for ${ }^{14} \mathrm{NH}_{2}, \bar{E}_{\text {osc }}\left({ }^{14} \mathrm{NH}_{2}\right)$, is:

$$
\begin{align*}
\bar{E}_{\text {osc }}\left({ }^{14} N H_{2}\right) & =2\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right) \\
& =2\left(-0.37798 \mathrm{eV}+\frac{1}{2}(0.40929 \mathrm{eV})\right)  \tag{13.344}\\
& =-0.34668 \mathrm{eV}
\end{align*}
$$

Using Eq. (13.341), Eqs. (13.342-13.344), and the ${ }^{14} \mathrm{ND}_{2}$ vibrational energy of $E_{v i b}=2410.79 \mathrm{~cm}^{-1}=0.29890 \mathrm{eV}$, calculated from the experimental ${ }^{14} \mathrm{NH}_{2}$ vibrational energy using Eq. (11.148), the corresponding $\bar{E}_{\text {osc }}\left({ }^{14} \mathrm{ND}_{2}\right)$ is:

$$
\begin{align*}
\bar{E}_{\text {osc }}\left({ }^{14} N D_{2}\right) & =2\left(-0.37798 \mathrm{eV}+\frac{1}{2}(0.29890 \mathrm{eV})\right)  \tag{13.345}\\
& =-0.45707 \mathrm{eV}
\end{align*}
$$

## TOTAL AND BOND ENERGIES OF ${ }^{14} \mathrm{NH}_{2}$ AND ${ }^{14} \mathrm{ND}_{2}$

$E_{T+o s c}\left({ }^{14} \mathrm{NH}_{2}\right)$, the total energy of the ${ }^{14} \mathrm{NH}_{2}$ including the Doppler term, is given by the sum of $E_{T}\left(\mathrm{NH}_{2}\right)$ (Eq. (13.321)) and $\bar{E}_{\text {osc }}\left({ }^{14} \mathrm{NH}_{2}\right)$ given Eqs. (13.339-13.344):

$$
\begin{align*}
E_{T+o s c}\left({ }^{14} N H_{2}\right) & =V_{e}+T+V_{m}+V_{p}+E(N 2 p)+\bar{E}_{\text {osc }}\left({ }^{14} N H_{2}\right)=E_{T}\left(N H_{2}\right)+\bar{E}_{\text {osc }}\left({ }^{14} N H_{2}\right)  \tag{13.346}\\
E_{T+o s c}\left({ }^{14} N H_{2}\right) & \left.=\left\{\begin{array}{l}
\left(\frac{-e^{2}}{4 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.53414 \mathrm{eV}\right) \\
-2\left((31.63536831 \mathrm{eV}) \sqrt{\frac{2 \hbar \sqrt{\frac{3}{2} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}}{m_{e}}}-\frac{1}{m_{e} c^{2}} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{array}\right)\right\}  \tag{13.347}\\
& =-48.73660 \mathrm{eV}-2\left(0.37798 \mathrm{eV}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{align*}
$$

From Eqs. (13.344) and (13.346-13.347), the total energy of ${ }^{14} \mathrm{NH}_{2}$ is:

$$
\begin{align*}
E_{T+o s c}\left({ }^{14} \mathrm{NH}_{2}\right) & =-48.73660 \mathrm{eV}+\bar{E}_{\text {osc }}\left({ }^{14} \mathrm{NH}_{2}\right) \\
& =-48.73660 \mathrm{eV}-2\left(0.37798 \mathrm{eV}-\frac{1}{2}(0.40929 \mathrm{eV})\right)  \tag{13.348}\\
& =-49.08328 \mathrm{eV}
\end{align*}
$$

where the experimental ${ }^{14} \mathrm{NH}_{2}$ vibrational energy was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term. $E_{T+\text { osc }}\left({ }^{14} N D_{2}\right)$, the total energy of ${ }^{14} N D_{2}$ including the Doppler term is given by the sum of $E_{T}\left(N D_{2}\right)=E_{T}\left(N H_{2}\right)$ (Eq. (13.321)) and $\bar{E}_{\text {osc }}\left({ }^{14} N D_{2}\right)$ given by Eq. (13.345).

$$
\begin{align*}
E_{T+o s c}\left({ }^{14} N D_{2}\right) & =-48.73660 \mathrm{eV}+\bar{E}_{\text {osc }}\left({ }^{14} \mathrm{ND}_{2}\right) \\
& =-48.73660 \mathrm{eV}-2\left(0.37798 \mathrm{eV}-\frac{1}{2}(0.29890 \mathrm{eV})\right)  \tag{13.349}\\
& =-49.19366 \mathrm{eV}
\end{align*}
$$

where the experimental ${ }^{14} \mathrm{NH}_{2}$ vibrational energy corrected for the reduced mass difference of hydrogen and deuterium was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term. The corresponding bond dissociation energy, $E_{D}$, is given by the sum of the total energies of the corresponding hydrogen nitride radical and hydrogen atom minus the total energy of dihydrogen nitride, $E_{T+o s c}\left({ }^{14} \mathrm{NH}_{2}\right)$.

Thus, $E_{D}$ of ${ }^{14} \mathrm{NH}_{2}$ is given by:

$$
\begin{equation*}
E_{D}\left({ }^{14} \mathrm{NH}_{2}\right)=E(H)+E\left({ }^{14} \mathrm{NH}\right)-E_{T+o s c}\left({ }^{14} \mathrm{NH}_{2}\right) \tag{13.350}
\end{equation*}
$$

where $E_{T}\left({ }^{14} N H\right)$ is given by the of the sum of the experimental energies of ${ }^{14} N$ (Eq. (13.251)), $H$ (Eq. (13.154)), and the negative of the bond energy of ${ }^{14} \mathrm{NH}$ (Eq. (13.312)):

$$
\begin{equation*}
E\left({ }^{14} \mathrm{NH}\right)=-13.59844 \mathrm{eV}-14.53414 \mathrm{eV}-3.42 \mathrm{eV}=-31.55258 \mathrm{eV} \tag{13.351}
\end{equation*}
$$

From Eqs. (13.154), (13.348), and (13.350-13.351), $E_{D}\left({ }^{14} \mathrm{NH}_{2}\right)$ is:

$$
\begin{align*}
E_{D}\left({ }^{14} N H_{2}\right) & =E(H)+E\left({ }^{14} \mathrm{NH}\right)-E_{T+o s c}\left({ }^{14} \mathrm{NH}_{2}\right) \\
& =-13.59844 \mathrm{eV}-31.55258 \mathrm{eV}-(-49.08328 \mathrm{eV})  \tag{13.352}\\
& =3.9323 \mathrm{eV}
\end{align*}
$$

The experimental ${ }^{14} \mathrm{NH}_{2}$ bond dissociation energy from Ref. [34] and Ref. [35] is:

$$
\begin{align*}
& E_{D}\left({ }^{14} \mathrm{NH}_{2}\right)=88 \pm 4 \mathrm{kcal} / \text { mole }=3.8160 \mathrm{eV}  \tag{13.353}\\
& E_{D}\left({ }^{14} \mathrm{NH}_{2}\right)=91.0 \pm 0.5 \mathrm{kcal} / \mathrm{mole}=3.9461 \mathrm{eV}
\end{align*}
$$

Similarly, $E_{D}$ of ${ }^{14} N D_{2}$ is given by:

$$
\begin{equation*}
E_{D}\left({ }^{14} N D_{2}\right)=E(D)+E\left({ }^{14} N D\right)-\left(E_{T+o s c}\left({ }^{14} N D_{2}\right)\right) \tag{13.355}
\end{equation*}
$$

where $E_{T}\left({ }^{14} N D\right)$ is given by the of the sum of the experimental energies of ${ }^{14} N$ (Eq. (13.251)), $D$ (Eq. (13.155)), and the negative of the bond energy of ${ }^{14} N D$ (Eq. (13.315)):

$$
\begin{equation*}
E\left({ }^{14} \mathrm{ND}\right)=-13.603 \mathrm{eV}-14.53414 \mathrm{eV}-3.513 \mathrm{eV}=-31.6506 \mathrm{eV} \tag{13.356}
\end{equation*}
$$

From Eqs. (13.155), (13.349), and (13.355-13.356), $E_{D}\left({ }^{14} N D_{2}\right)$ is

$$
\begin{equation*}
E_{D}\left({ }^{14} N D_{2}\right)=-13.603 \mathrm{eV}-31.6506 \mathrm{eV}-(-49.19366 \mathrm{eV})=3.9401 \mathrm{eV} \tag{13.357}
\end{equation*}
$$

The ${ }^{14} \mathrm{ND}_{2}$ bond dissociation energy calculated from the average of the experimental bond energies [34-35] and vibrational energy of ${ }^{14} \mathrm{NH}_{2}$ [33] is:

$$
\begin{align*}
E_{D}\left({ }^{14} N D_{2}\right) & =E_{D}\left({ }^{14} N H_{2}\right)+\frac{1}{2}\left(E_{v i b}\left({ }^{(44} N H_{2}\right)-E_{v i b}\left({ }^{14} N D_{2}\right)\right)  \tag{13.358}\\
& =\frac{1}{2}(3.8160 \mathrm{eV}+3.9461 \mathrm{eV})+\frac{1}{2}(0.40929 \mathrm{eV}-0.29890 \mathrm{eV})=3.9362 \mathrm{eV}
\end{align*}
$$

## BOND ANGLE OF $\mathrm{NH}_{2}$

The $\mathrm{NH}_{2} \mathrm{MO}$ comprises a linear combination of two $\mathrm{N}-\mathrm{H}$-bond MOs. Each $N-H$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and the $N 2 p_{x} \mathrm{AO}$ or the $N 2 p_{y}$ AO with a relative charge density of 0.75 to 1.25 ; otherwise, the $N 2 p$ AOs are the same as those of the nitrogen atom. A bond is also possible between the two H atoms of the $N-H$ bonds. Such $H-H$ bonding would decrease the $N-H$ bond strength since electron density would be shifted from the $N-H$ bonds to the $H-H$ bond. Thus, the bond angle between the two $N-H$ bonds is determined by the condition that the total energy of the $H_{2}$-type ellipsoidal MO between the terminal $H$ atoms of the $N-H$ bonds is zero. From Eqs. (11.79) and (13.228), the distance from the origin to each focus of the $H-H$ ellipsoidal MO is

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 2 a}}=\sqrt{\frac{a a_{0}}{2}} \tag{13.359}
\end{equation*}
$$

The internuclear distance from Eq. (13.229) is:

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{\frac{a a_{0}}{2}} \tag{13.360}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal $H-H$ MO $b=c$ is given by Eq. (13.167).
Since the two $\mathrm{H}_{2}$-type ellipsoidal MOs comprise $75 \%$ of the H electron density of $\mathrm{H}_{2}$ and the energy of each $\mathrm{H}_{2}$-type ellipsoidal MO is matched to that of the $N 2 p \mathrm{AO}$; the component energies and the total energy $E_{T}$ of the $H-H$ bond are given by Eqs. (13.67-13.73) except that $V_{e}, T$, and $V_{m}$ are corrected for the energy matching factor of 0.93613 given in Eq. (13.248). Substitution of Eq. (13.359) into Eq. (13.233) with the energy-matching factor gives:

$$
0=\left[\begin{array}{l}
\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left[(0.93613)^{-1}\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right]\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}}{m_{e} c^{2}}}\right]  \tag{13.361}\\
+\frac{1}{2} \hbar \sqrt{\frac{\frac{0.75 e^{2}}{8 \pi \varepsilon_{0} a^{3}}-\frac{e^{2}}{8 \pi \varepsilon_{0}\left(a+c^{\prime}\right)^{3}}}{0.5 m_{p}}}
\end{array}\right]
$$

From the energy relationship given by Eq. (13.361) and the relationship between the axes given by Eqs. (13.359-13.360) and (13.167-13.168), the dimensions of the $H-H$ MO can be solved.

The most convenient way to solve Eq. (13.361) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a=4.9500 a_{0}=2.6194 \times 10^{-10} \mathrm{~m} \tag{13.362}
\end{equation*}
$$

Substitution of Eq. (13.362) into Eq. (13.359) gives:

$$
\begin{equation*}
c^{\prime}=1.5732 a_{0}=8.3251 \times 10^{-11} \mathrm{~m} \tag{13.363}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.363) by two is:

$$
\begin{equation*}
2 c^{\prime}=3.1464 a_{0}=1.6650 \times 10^{-10} \mathrm{~m} \tag{13.364}
\end{equation*}
$$

Substitution of Eqs. (13.362-13.363) into Eq. (13.167) gives:

$$
\begin{equation*}
b=c=4.6933 a_{0}=2.4836 \times 10^{-10} \mathrm{~m} \tag{13.365}
\end{equation*}
$$

Substitution of Eqs. (13.362-13.363) into Eq. (13.168) gives:

Using, $2{c^{\prime}}_{H-H}$ (Eq. (13.364)), the distance between the two $H$ atoms when the total energy of the corresponding MO is zero (Eq. (13.361)), and $2 c_{N-H}^{\prime}$ (Eq. (13.325)), the internuclear distance of each $N-H$ bond, the corresponding bond angle can be determined from the law of cosines. Using, Eq. (13.242), the bond angle $\theta$ between the $N-H$ bonds is:

$$
\begin{equation*}
\theta=\cos ^{-1}\left(\frac{2(1.9703)^{2}-(3.1464)^{2}}{2(1.9703)^{2}}\right)=\cos ^{-1}(-0.2751)=105.969^{\circ} \tag{13.367}
\end{equation*}
$$

The experimental angle between the $N-H$ bonds is [32]:
$\theta=103.3^{\circ}$
The results of the determination of bond parameters of $\mathrm{NH}_{2}$ and $\mathrm{ND}_{2}$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## AMMONIA ( $\mathrm{NH}_{3}$ )

Ammonia $\left(\mathrm{NH}_{3}\right)$ is formed by the reaction of a hydrogen atom with a dihydrogen nitride radical:

$$
\begin{equation*}
\mathrm{NH}_{2}+\mathrm{H} \rightarrow \mathrm{NH}_{3} \tag{13.369}
\end{equation*}
$$

$\mathrm{NH}_{3}$ can be solved using the same principles as those used to solve $\mathrm{NH}_{2}$ except that three rather than two $\mathrm{H}_{2}$-type prolate spheroidal molecular orbitals (MOs) serve as basis functions in a linear combination with nitrogen atomic orbitals (AOs) to form the MO of $\mathrm{NH}_{3}$.

## FORCE BALANCE OF $\mathrm{NH}_{3}$

$\mathrm{NH}_{3}$ comprises three chemical bonds between nitrogen and hydrogen. Each $N-H$ bond comprises two spin-paired electrons with one from an initially unpaired electron of the nitrogen atom and the other from the hydrogen atom. Each $H$-atom electron forms a $H_{2}$-type ellipsoidal MO with one of the initially unpaired $N$-atom electrons, $2 p_{x}, 2 p_{y}$, or $2 p_{z}$, such that the proton and the $N$ nucleus serve as the foci. The initial $N$ electron configuration given in the Seven-Electron Atoms section is $1 s^{2} 2 s^{2} 2 p^{3}$, and the orbital arrangement is given by Eqs. (10.134) and (13.246). The radius and the energy of the $N 2 p$ shell are unchanged with bond formation. The central paramagnetic force due to spin of each $N-H$ bond is provided by the spin-paring force of the $\mathrm{NH}_{3} \mathrm{MO}$ that has the symmetry of an $s$ orbital that superimposes with the $N 2 p$ orbitals such that the corresponding angular momenta are unchanged.

As in the case of $\mathrm{H}_{2}$, each of three $\mathrm{N}-\mathrm{H}$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into the $N$ atom for distances shorter than the radius of the $2 p$ shell since it is energetically unfavorable. Thus, the MO surface comprises a prolate spheroid at each $H$ proton that is continuous with the $2 p$ shell at the $N$ atom. The energies in the $\mathrm{NH}_{3}$ MO involve only each $N 2 p$ and each $H 1 s$ electron with the formation of each $N-H$ bond. The sum of the energies of the prolate spheroids is matched to that of the $2 p$ shell. The forces are determined by these energies. As in the cases of NH and $\mathrm{NH}_{2}$, the linear combination of each $\mathrm{H}_{2}$-type ellipsoidal MO with each $\mathrm{N} 2 p$ AO must involve a $25 \%$ contribution from the $H_{2}$-type ellipsoidal MO to the $N 2 p \mathrm{AO}$ in order to match potential, kinetic, and orbital energy relationships. Thus, the $\mathrm{NH}_{3}$ MO must comprise three $\mathrm{N}-\mathrm{H}$ bonds with each comprising $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO ( $1 / 2+25 \%$ ) and a nitrogen AO :

$$
\begin{equation*}
\left[1 \mathrm{~N} 2 p_{x} A O+0.75 \mathrm{H}_{2} \mathrm{MO}\right]+\left[1 \mathrm{~N} 2 p_{y} \mathrm{AO}+0.75 \mathrm{H}_{2} \mathrm{MO}\right]+\left[1 \mathrm{~N} 2 p_{z} A O+0.75 \mathrm{H}_{2} \mathrm{MO}\right] \rightarrow N H_{3} M O \tag{13.370}
\end{equation*}
$$

The force constant $k^{\prime}$ of each $H_{2}$-type-ellipsoidal-MO component of the $\mathrm{NH}_{3} \mathrm{MO}$ is given by Eq. (13.248). The distance from the origin of each $N-H$-bond MO to each focus $c^{\prime}$ is given by Eq. (13.249). The internuclear distance is given by Eq. (13.250). The length of the semiminor axis of the prolate spheroidal $N-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $N-H$-bond MO. Since each of the three prolate spheroidal $N-H$-bond MOs comprises a $H_{2}$-type-ellipsoidal MO that transitions to the $N$ AO, the energy $E$ in Eq. (13.251) adds to that of the three corresponding $\mathrm{H}_{2}$-type ellipsoidal MOs to give the total energy of the $\mathrm{NH}_{3} \mathrm{MO}$. From the energy equation and the relationship between the axes, the dimensions of the $\mathrm{NH}_{3} \mathrm{MO}$ are solved.

The energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ are three times those of $O H$ and $N H$ given by Eqs. (13.67-13.73) and 1.5 times those of $\mathrm{H}_{2} \mathrm{O}$ given by Eqs. (13.172-13.178). Similarly to $\mathrm{H}_{2} \mathrm{O}$, since each prolate spheroidal $\mathrm{H}_{2}$-type MO transitions to the $N \mathrm{AO}$ and the energy of the $N 2 p$ shell must remain constant and equal to the negative of the ionization energy given by Eq. (13.251), the total energy $E_{T}\left(N H_{3}\right)$ of the $N H_{3} \mathrm{MO}$ is given by the sum of the energies of the orbitals
corresponding to the composition of the linear combination of the $N \mathrm{AO}$ and the three $H_{2}$-type ellipsoidal MOs that forms the $\mathrm{NH}_{3} \mathrm{MO}$ as given by Eq. (13.370):

$$
\begin{align*}
E_{T}\left(N H_{3}\right) & =E_{T}+E(2 p \text { shell }) \\
& =E_{T}-E(\text { ionization; } N)  \tag{13.371}\\
& =-3 \frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.53414 \mathrm{eV}
\end{align*}
$$

The three hydrogen atoms and the nitrogen atom can achieve an energy minimum as a linear combination of three $\mathrm{H}_{2}$-type ellipsoidal MOs each having the proton and the nitrogen nucleus as the foci. Each $N-H$-bond MO comprises the same $N 2 p$ shell of constant energy given by Eq. (13.251). Thus, an energy term of the $\mathrm{NH}_{3} \mathrm{MO}$ is given by the sum of the three $H_{2}$-type ellipsoidal MOs given by Eq. (11.212) minus the energy of the redundant nitrogen atom of the linear combination given by Eq. (13.251). The total sum is determined by the energy matching condition of the binding atoms.

In Eq. (13.248), the equipotential condition of the union of each $H_{2}$-type-ellipsoidal-MO and the $N$ AO was met when the force constant used to determine the ellipsoidal parameter $c^{\prime}$ was normalized by the ratio of the ionization energy of $N$ 14.53414 eV [6] and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). This normalized the force to match that of the Coulombic force alone to meet the force matching condition of the $N H$ MO under the influence of the proton and the $N$ nucleus. The minimum total energy of the $\mathrm{NH}_{3} \mathrm{MO}$ from the sum of energies of a linear combination from four atoms is determined using the energy matching condition of Eq. (13.248). Since each of the three prolate spheroidal $\mathrm{N}-\mathrm{H}$-bond MOs of $\mathrm{NH}_{3}$ comprises a $H_{2}$-type-ellipsoidal MO that transitions to the N AO and the energy matching condition is met, the nitrogen energy $E$ (Eq. (13.251)) and the energy (Eq. (1.264)) of a hydrogen atomic orbital ( $H \mathrm{AO}$ ), $E_{\text {Coulomb }}(H)$, corresponding to the Coulombic force of $+e$ from the nitrogen nucleus is subtracted from the sum of the energies of the three corresponding $H_{2}$-type ellipsoidal MOs to given an energy minimum. From another perspective, the electron configuration of $\mathrm{NH}_{2}$ is equivalent to that of OH and is given by Eq. (10.174). $\mathrm{NH}_{2}$ serves as a one-electron atom that is energy matched by the HAO as a basis element to minimize the energy of $\mathrm{NH}_{3}$ in the formation of the third $\mathrm{N}-\mathrm{H}-$ bond.

$$
\begin{align*}
E_{T}\left(3 H_{2}-N-H\right) & =\left\{\begin{array}{l}
-3 \frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}\left[\left(2 \sqrt{2}-\sqrt{2}+\frac{\sqrt{2}}{2}\right) \ln \frac{\sqrt{2}+1}{\sqrt{2}-1}-\sqrt{2}\right] \\
-E(N 2 p \text { shell })-E_{\text {Couloob }}(H)
\end{array}\right\}  \tag{13.372}\\
& =3(-31.63536831 \mathrm{eV})-(-14.53414 \mathrm{eV}-13.605804 \mathrm{eV})=-66.76616 \mathrm{eV}
\end{align*}
$$

$E_{T}\left(\mathrm{NH}_{3}\right)$ given by Eq. (13.371) is set equal to Eq. (13.372), three times the energy of the $H_{2}$-type ellipsoidal MO minus the energy of the $N 2 p$ shell and the $H \mathrm{AO}$ :

$$
\begin{equation*}
E_{T}\left(N H_{3}\right)=-3 \frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.53414 \mathrm{eV}=-66.76616 \mathrm{eV} \tag{13.373}
\end{equation*}
$$

From the energy relationship given by Eq. (13.373) and the relationship between the axes given by Eqs. (13.248-13.250) and (13.62-13.63), the dimensions of the $\mathrm{NH}_{3} \mathrm{MO}$ can be solved.

Substitution of Eq. (13.249) into Eq. (13.373) gives:

$$
\begin{equation*}
\frac{3 e^{2}}{8 \pi \varepsilon_{0} \sqrt{0.712154 a a_{0}}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{0.712154 a a_{0}}}{a-\sqrt{0.712154 a a_{0}}}-1\right]=e 52.23202 \tag{13.374}
\end{equation*}
$$

The most convenient way to solve Eq. (13.374) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is:

$$
\begin{equation*}
a=1.34750 a_{0}=7.13066 \times 10^{-11} \mathrm{~m} \tag{13.375}
\end{equation*}
$$

Substitution of Eq. (13.375) into Eq. (13.249) gives:

$$
\begin{equation*}
c^{\prime}=0.97961 a_{0}=5.18385 \times 10^{-11} \mathrm{~m} \tag{13.376}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.376) by two is:

$$
\begin{equation*}
2 c^{\prime}=1.95921 a_{0}=1.03677 \times 10^{-10} \mathrm{~m} \tag{13.377}
\end{equation*}
$$

The experimental bond distance is [32]:

$$
\begin{equation*}
2 c^{\prime}=1.012 \times 10^{-10} \mathrm{~m} \tag{13.378}
\end{equation*}
$$

Substitution of Eqs. (13.375-13.376) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=0.92527 a_{0}=4.89633 \times 10^{-11} \mathrm{~m} \tag{13.379}
\end{equation*}
$$

Substitution of Eqs. (13.375-13.376) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.72698 \tag{13.380}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $N$ atom comprise the foci of the $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of each $H_{2}$-type ellipsoidal MO and the $N 2 p_{x}, N 2 p_{y}$, or $N 2 p_{z}$ AO are given by Eqs. (13.84-13.95), (13.261-13.270), and (13.261-13.270). Using Eqs. (13.375-13.377) and (13.379-13.380), the polar intersection angle $\theta^{\prime}$ given by Eq. (13.261) with $r_{n}=r_{7}=0.93084 a_{0}$ is:

$$
\begin{equation*}
\theta^{\prime}=115.89^{\circ} \tag{13.381}
\end{equation*}
$$

Then, the angle $\theta_{N 2 p A O}$ the radial vector of the $N 2 p_{x}, N 2 p_{y}$, or $N 2 p_{z}$ AO makes with the internuclear axis is

$$
\begin{equation*}
\theta_{N 2 p A O}=180^{\circ}-115.89^{\circ}=64.11^{\circ} \tag{13.382}
\end{equation*}
$$

as shown in Figure 13.5. The parametric angle $\theta_{\mathrm{H}_{2} \mathrm{MO}}$ given by Eqs. (13.264-13.265), (13.379), and (13.382) is:

$$
\begin{equation*}
\theta_{H_{2} M O}=64.83^{\circ} \tag{13.383}
\end{equation*}
$$

Then, the distance $d_{\mathrm{H}_{2} \mathrm{MO}}$ along the internuclear axis from the origin of $\mathrm{H}_{2}$-type ellipsoidal MO to the point of intersection of the orbitals given by Eqs. (13.267), (13.375), and (13.383) is:

$$
\begin{equation*}
d_{H_{2} M O}=0.57314 a_{0}=3.03292 \times 10^{-11} \mathrm{~m} \tag{13.384}
\end{equation*}
$$

The distance $d_{N 2 p A O}$ along the internuclear axis from the origin of the $N$ atom to the point of intersection of the orbitals given by Eqs. (13.269), (13.376), and (13.384) is:

$$
\begin{equation*}
d_{N 2 p A O}=0.40647 a_{0}=2.15093 \times 10^{-11} \mathrm{~m} \tag{13.385}
\end{equation*}
$$

As shown in Eq. (13.370), in addition to the $p$-orbital charge-density modulation, the uniform charge-density in the $p_{x}$, $p_{y}$, and $p_{z}$ orbitals is increased by a factor of 0.25 and the $H$ atoms are each decreased by a factor of 0.25 . Using the orbital composition of $\mathrm{NH}_{3}$ (Eq. (13.370)), the radii of $N 1 s=0.14605 a_{0}$ (Eq. (10.51)), $N 2 s=0.69385 a_{0}$ (Eq. (10.62)), and $N 2 p=0.93084 a_{0}$ (Eq. (10.142)) shells, and the parameters of the $N H_{3}$ MO given by Eqs. (13.3-13.4) and (13.375-13.385), the charge-density of the $\mathrm{NH}_{3} \mathrm{MO}$ comprising the linear combination of three $\mathrm{N}-\mathrm{H}$-bond MOs ( NH -type ellipsoidal MOs given in the Energies of $N H$ section) according to Eq. (13.370) is shown in Figure 13.8. Each $N-H$-bond MO comprises a $H_{2}$-type ellipsoidal MO and an $N 2 p$ AO having the dimensional diagram shown in Figure 13.5.

Figure 13.8. $N H_{3} \mathrm{MO}$ comprising the linear combination of three $N-H$-bonds. Each $N-H$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and the $N 2 p_{x}, N 2 p_{y}$, or $N 2 p_{z}$ AO with a relative charge-density of 0.75 to 1.25 ; otherwise, the $N 2 p$ orbitals are the same as those of the nitrogen atom. The each internuclear axis of one $N-H$ bond is perpendicular to the bonding $p$ orbital. (A) Color scale, translucent view of the charge-density of the $\mathrm{NH}_{3}$ MO shown obliquely from the top. For each $N-H$ bond, the ellipsoidal surface of each $H_{2}$-type ellipsoidal MO transitions to a $N 2 p$ AO. The $N 2 p$ shell, the $N 2 s$ shell, the $N 1 s$ shell, and the nuclei (red, not to scale) are shown. (B) Off-center cut-away view showing the complete inner most $N 1 s$ shell, and moving radially, the cross section of the $N 2 s$ shell, the $N 2 p$ shell, and the $H_{2}$-type ellipsoidal MO that transitions to a $N 2 p \mathrm{AO}$ for each $N-H$ bond. Bisector current not shown. (C)-(E) Color scale, side-on, top, and bottom translucent views of the charge-density of the $\mathrm{NH}_{3} \mathrm{MO}$, respectively.

## ENERGIES OF $\mathrm{NH}_{3}$

The energies of $\mathrm{NH}_{3}$ given by the substitution of the semiprincipal axes ((Eqs. (13.375-13.377) and (13.379)) into the energy equations (Eqs. (13.67-13.73)) multiplied by three are:

$$
\begin{align*}
& V_{e}=3\left(\frac{3}{4}\right) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-115.28799 \mathrm{eV}  \tag{13.386}\\
& V_{p}=3 \frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=41.66718 \mathrm{eV}  \tag{13.387}\\
& T=3\left(\frac{3}{4}\right) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=42.77848 \mathrm{eV}  \tag{13.388}\\
& V_{m}=3\left(\frac{3}{4}\right) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-21.38924 \mathrm{eV}  \tag{13.389}\\
& E_{T}\left(N H_{3}\right)=-3 \frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.53414 \mathrm{eV}=-66.76571 \mathrm{eV} \tag{13.390}
\end{align*}
$$

where $E_{T}\left(\mathrm{NH}_{3}\right)$ is given by Eq. (13.371) which is reiteratively matched to Eq. (13.372) within five-significant-figure round-off error.

## VIBRATION OF $\mathrm{NH}_{3}$

The vibrational energy levels of $\mathrm{NH}_{3}$ may be solved as three equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [2] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERM OF $\mathrm{NH}_{3}$

The radiation reaction force in the case of the vibration of $\mathrm{NH}_{3}$ in the transition state corresponds to the Doppler energy, $E_{D}$, given by Eq. (11.181) and Eqs. (13.22) and (13.144) that is dependent on the motion of the electrons and the nuclei. The kinetic energy of the transient vibration is derived from the corresponding central forces. The equations of the radiation reaction force of ammonia are the same as those of the corresponding water and dihydrogen and dideuterium nitride radicals with the substitution of the ammonia parameters. Using Eqs. (11.136) and (13.207-13.209), the angular frequency of the reentrant oscillation in the transition state is

$$
\begin{equation*}
\omega=\sqrt{\frac{\left(\frac{3}{2}\right) \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=5.68887 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{13.391}
\end{equation*}
$$

where $b$ is given by Eq. (13.379). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 5.68887 \times 10^{16} \mathrm{rad} / \mathrm{s}=37.44514 \mathrm{eV} \tag{13.392}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each $H_{2}$-type MO acting independently due to the $D_{3 h}$ symmetry point group, for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.392) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-31.6353683 \mathrm{eV} \sqrt{\frac{2 e(37.44514 \mathrm{eV})}{m_{e} c^{2}}}=-0.38298 \mathrm{eV} \tag{13.393}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of $\mathrm{NH}_{3}$ due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.393) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of $\mathrm{NH}_{3}$. Using the experimental ${ }^{14} \mathrm{NH}_{3}$ vibrational energy of $E_{v i b}=3443.59 \mathrm{~cm}^{-1}=0.426954 \mathrm{eV}$ [36] gives:

$$
\begin{equation*}
\bar{E}_{o s c}^{\prime}=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}} \tag{13.394}
\end{equation*}
$$

$$
\begin{equation*}
\bar{E}_{o s c}^{\prime}=-0.38298 \mathrm{eV}+\frac{1}{2}(0.426954 \mathrm{eV})=-0.16950 \mathrm{eV} \tag{13.395}
\end{equation*}
$$

per bond. The reentrant orbit for the binding of a hydrogen atom to a $\mathrm{NH}_{2}$ radical involves three $\mathrm{N}-\mathrm{H}$ bonds. Since the vibration and reentrant oscillation is along three bonds, $\bar{E}_{\text {osc }}$ for ${ }^{14} \mathrm{NH}_{3}, \bar{E}_{\text {osc }}\left({ }^{14} \mathrm{NH}_{3}\right)$, is:

$$
\begin{equation*}
\bar{E}_{\text {osc }}\left({ }^{14} \mathrm{NH}_{3}\right)=3\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)=3\left(-0.38298 \mathrm{eV}+\frac{1}{2}(0.426954 \mathrm{eV})\right)=-0.50850 \mathrm{eV} \tag{13.396}
\end{equation*}
$$

Using Eq. (13.393), Eqs. (13.394-13.396), and the ${ }^{14} N D_{3}$ experimental vibrational energy of $E_{v i b}=2563.96 \mathrm{~cm}^{-1}=0.317893 \mathrm{eV}$ [36], the corresponding $\bar{E}_{\text {osc }}\left({ }^{14} \mathrm{ND}_{2}\right)$ is:

$$
\begin{equation*}
\bar{E}_{\text {osc }}\left({ }^{14} N D_{3}\right)=3\left(-0.38298 \mathrm{eV}+\frac{1}{2}(0.317893 \mathrm{eV})\right)=-0.67209 \mathrm{eV} \tag{13.397}
\end{equation*}
$$

## TOTAL AND BOND ENERGIES OF ${ }^{14} \mathrm{NH}_{3}$ AND ${ }^{14} \mathrm{ND}_{3}$

$E_{T+o s c}\left({ }^{14} \mathrm{NH}_{3}\right)$, the total energy of the ${ }^{14} \mathrm{NH}_{3}$ including the Doppler term, is given by the sum of $E_{T}\left(\mathrm{NH}_{3}\right)$ (Eq. (13.373)) and $\bar{E}_{\text {osc }}\left({ }^{14} \mathrm{NH}_{3}\right)$ given Eqs. (13.391-13.396):

$$
\left.\begin{array}{rl}
E_{T+o s c}\left({ }^{14} N H_{3}\right) & =V_{e}+T+V_{m}+V_{p}+E(N 2 p)+\bar{E}_{\text {osc }}\left({ }^{14} N H_{3}\right)=E_{T}\left(N H_{3}\right)+\bar{E}_{\text {osc }}\left({ }^{14} N H_{3}\right) \\
E_{T+\text { osc }}\left({ }^{14} N H_{3}\right) & =\left\{\begin{array}{l}
\left(3 \frac{-e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.53414 \mathrm{eV}\right) \\
-3(31.63536831 \mathrm{eV}) \sqrt{\frac{\sqrt{\frac{3}{2} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}}{m_{e}}} \\
m_{e} c^{2}
\end{array} \frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right) \tag{13.399}
\end{array}\right\}
$$

From Eqs. (13.396) and (13.398-13.399), the total energy of ${ }^{14} \mathrm{NH}_{2}$ is:

$$
\begin{align*}
E_{T+o s c}\left({ }^{14} \mathrm{NH}_{3}\right) & =-66.76616 \mathrm{eV}+\bar{E}_{\text {osc }}\left({ }^{14} \mathrm{NH}_{3}\right) \\
& =-66.76616 \mathrm{eV}-3\left(0.38298 \mathrm{eV}-\frac{1}{2}(0.426954 \mathrm{eV})\right)  \tag{13.400}\\
& =-67.27466 \mathrm{eV}
\end{align*}
$$

where the experimental ${ }^{14} \mathrm{NH}_{3}$ vibrational energy was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term. $E_{T+\text { osc }}\left({ }^{14} N D_{3}\right)$, the total energy of ${ }^{14} N D_{3}$ including the Doppler term is given by the sum of $E_{T}\left(N D_{3}\right)=E_{T}\left(N H_{3}\right)$ (Eq. (13.373)) and $\bar{E}_{\text {osc }}\left({ }^{14} N D_{3}\right)$ given by Eq. (13.397):

$$
\begin{align*}
E_{T+\text { osc }}\left({ }^{14} N D_{3}\right) & =-66.76616 \mathrm{eV}+\bar{E}_{\text {osc }}\left({ }^{14} N D_{3}\right) \\
& =-66.76616 \mathrm{eV}-3\left(0.38298 \mathrm{eV}-\frac{1}{2}(0.317893 \mathrm{eV})\right)  \tag{13.401}\\
& =-67.43780 \mathrm{eV}
\end{align*}
$$

where the experimental ${ }^{14} N D_{3}$ vibrational energy was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term. The corresponding bond dissociation energy, $E_{D}$, is given by the sum of the total energies of the corresponding dihydrogen nitride radical and hydrogen atom minus the total energy of ammonia, $E_{T+o s c}\left({ }^{14} \mathrm{NH}_{3}\right)$.

Thus, $E_{D}$ of ${ }^{14} \mathrm{NH}_{3}$ is given by:

$$
\begin{equation*}
E_{D}\left({ }^{14} N H_{3}\right)=E(H)+E\left({ }^{14} N H_{2}\right)-E_{T+o s c}\left({ }^{14} N H_{3}\right) \tag{13.402}
\end{equation*}
$$

where $E_{T}\left({ }^{14} \mathrm{NH}_{2}\right)$ is given by the of the sum of the experimental energies of ${ }^{14} \mathrm{~N}$ (Eq. (13.251)), two $H$ (Eq. (13.154)), and the negative of the bond energies of ${ }^{14} \mathrm{NH}$ (Eq. (13.312)) and ${ }^{14} \mathrm{NH}_{2}$ (Eq. (13.354)):

$$
\begin{equation*}
E\left({ }^{14} \mathrm{NH}_{2}\right)=2(-13.59844 \mathrm{eV})-14.53414 \mathrm{eV}-3.42 \mathrm{eV}-3.946 \mathrm{eV}=-49.09709 \mathrm{eV} \tag{13.403}
\end{equation*}
$$

From Eqs. (13.154), (13.400), and (13.402-13.403), $E_{D}\left({ }^{14} \mathrm{NH}_{2}\right)$ is:

$$
\begin{align*}
E_{D}\left({ }^{14} N H_{3}\right) & =E(H)+E\left({ }^{14} \mathrm{NH}_{2}\right)-E_{T+o s c}\left({ }^{14} \mathrm{NH}_{3}\right)  \tag{13.404}\\
& =-13.59844 \mathrm{eV}-49.09709 \mathrm{eV}-(-67.27466 \mathrm{eV})=4.57913 \mathrm{eV}
\end{align*}
$$

The experimental ${ }^{14} \mathrm{NH}_{3}$ bond dissociation energy [37] is:

$$
\begin{equation*}
E_{D}\left({ }^{14} \mathrm{NH}_{3}\right)=4.60155 \mathrm{eV} \tag{13.405}
\end{equation*}
$$

Similarly, $E_{D}$ of ${ }^{14} \mathrm{ND}_{3}$ is given by:

$$
\begin{equation*}
E_{D}\left({ }^{14} N D_{3}\right)=E(D)+E\left({ }^{14} N D_{2}\right)-\left(E_{T+\text { osc }}\left({ }^{14} N D_{3}\right)\right) \tag{13.406}
\end{equation*}
$$

where $E_{T}\left({ }^{14} N D_{2}\right)$ is given by the of the sum of the experimental energies of ${ }^{14} N$ (Eq. (13.251)), two times the energy of $D$ (Eq. (13.155)), and the negative of the bond energies of ${ }^{14} N D$ (Eq. (13.315)) and ${ }^{14} N D_{2}$ (Eq. (13.358)):

$$
\begin{equation*}
E\left({ }^{14} N D_{2}\right)=2(-13.603 \mathrm{eV})-14.53414 \mathrm{eV}-3.5134 \mathrm{eV}-3.9362 \mathrm{eV}=-49.18981 \mathrm{eV} \tag{13.407}
\end{equation*}
$$

From Eqs. (13.155), (13.401), and (13.406-13.407), $E_{D}\left({ }^{14} N D_{3}\right)$ is:

$$
\begin{equation*}
E_{D}\left({ }^{14} N D_{3}\right)=-13.603 \mathrm{eV}-49.18981 \mathrm{eV}-(-67.43780 \mathrm{eV})=4.64499 \mathrm{eV} \tag{13.408}
\end{equation*}
$$

The experimental ${ }^{14} N D_{3}$ bond dissociation energy [37] is:

$$
\begin{equation*}
E_{D}\left({ }^{14} N D_{3}\right)=4.71252 \mathrm{eV} \tag{13.409}
\end{equation*}
$$

## BOND ANGLE OF $\mathrm{NH}_{3}$

Using, $2 c_{H-H}^{\prime}$ (Eq. (13.364)), the distance between the two $H$ atoms when the total energy of the corresponding MO is zero (Eq. (13.361)), and $2{c^{\prime}}_{N-H}$, the internuclear distance of each $N-H$ bond (Eq. (13.377)), the corresponding bond angle can be determined from the law of cosines. Using Eq. (13.367), the bond angle $\theta$ between the $N-H$ bonds is:

$$
\begin{equation*}
\theta=\cos ^{-1}\left(\frac{2(1.95921)^{2}-(3.14643)^{2}}{2(1.95921)^{2}}\right)=\cos ^{-1}(-0.28956)=106.67^{\circ} \tag{13.410}
\end{equation*}
$$

The experimental angle between the $N-H$ bonds is [36]:

$$
\begin{equation*}
\theta=106.67^{\circ} \tag{13.411}
\end{equation*}
$$

The $\mathrm{NH}_{3}$ molecule has a pyramidal structure with the nitrogen atom along the z -axis at the apex and the hydrogen atoms at the base in the xy-plane. Since any two $N-H$ bonds form an isosceles triangle, the distance $d_{o r i g i n-H}$ from the origin to the nucleus of a hydrogen atom is given by:

$$
\begin{equation*}
d_{\text {origin }-H}=\frac{2 c_{H-H}^{\prime}}{2 \sin 60^{\circ}} \tag{13.412}
\end{equation*}
$$

Substitution of Eq. (13.364) into Eq. (13.412) gives:

$$
\begin{equation*}
d_{o r i g i n-H}=1.81659 a_{0} \tag{13.413}
\end{equation*}
$$

The height along the z -axis of the pyramid from the origin to $N$ nucleus $d_{\text {height }}$ is given by:

$$
\begin{equation*}
d_{\text {height }}=\sqrt{\left(2 c_{N-H}^{\prime}\right)^{2}-\left(d_{\text {origin }-H}\right)^{2}} \tag{13.414}
\end{equation*}
$$

Substitution of Eqs. (13.377) and (13.413) into Eq. (13.414) gives:

$$
\begin{equation*}
d_{\text {height }}=0.73383 a_{0} \tag{13.415}
\end{equation*}
$$

The angle $\theta_{v}$ of each $N-H$ bond from the z -axis is given by:

$$
\begin{equation*}
\theta_{v}=\tan ^{-1}\left(\frac{d_{\text {origin }-H}}{d_{\text {height }}}\right) \tag{13.416}
\end{equation*}
$$

Substitution of Eqs. (13.413) and (13.415) into Eq. (13.416) gives:

$$
\begin{equation*}
\theta_{v}=68.00^{\circ} \tag{13.417}
\end{equation*}
$$

The $\mathrm{NH}_{3}$ MO shown in Figure 13.8 was rendered using these parameters.
The results of the determination of bond parameters of $\mathrm{NH}_{3}$ and $\mathrm{ND}_{3}$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## HYDROGEN CARBIDE ( CH )

The methane molecule can be solved by first considering the solution of the hydrogen carbide, dihydrogen carbide, and methyl radicals. The former is formed by the reaction of a hydrogen atom and a carbon atom:

$$
\begin{equation*}
\mathrm{H}+\mathrm{C} \rightarrow \mathrm{CH} \tag{13.418}
\end{equation*}
$$

The hydrogen carbide radicals, CH and $\mathrm{CH}_{2}$, methyl radical, $\mathrm{CH}_{3}$, and methane, $\mathrm{CH}_{4}$, can be solved using the same principles as those used to solve $\mathrm{OH}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}, \mathrm{NH}_{2}$, and $\mathrm{NH}_{3}$ with the exception that the carbon $2 s$ and $2 p$ shells hybridize to form a single $2 s p^{3}$ shell as an energy minimum.

## FORCE BALANCE OF $C H$

CH comprises two spin-paired electrons in a chemical bond between the carbon atom and the hydrogen atom. The CH radical molecular orbital ( MO ) is determined by considering properties of the binding atoms and the boundary constraints. The prolate spheroidal $\mathrm{H}_{2} \mathrm{MO}$ developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules section satisfies the boundary constraints; thus, the $H$-atom electron forms a $H_{2}$-type ellipsoidal MO with one of the $C$-atom electrons. However, such a bond is not possible with the outer $C$ electrons in their ground state since the resulting $H_{2}$-type ellipsoidal MO would have a shorter internuclear distance than the radius of the carbon $2 p$ shell, which is not energetically stable. Thus, when bonding the carbon $2 s$ and $2 p$ shells hybridize to form a single $2 s p^{3}$ shell as an energy minimum.
The $C$ electron configuration given in the Six-Electron Atoms section is $1 s^{2} 2 s^{2} 2 p^{2}$, and the orbital arrangement is:

$$
\begin{align*}
& 2 \mathrm{p} \text { state } \\
& \frac{\uparrow}{1} \frac{\uparrow}{0} \frac{}{-1} \tag{13.419}
\end{align*}
$$

corresponding to the ground state ${ }^{3} P_{0}$. The radius $r_{6}$ of the $2 p$ shell given by Eq. (10.122) is:

$$
\begin{equation*}
r_{6}=1.20654 a_{0} \tag{13.420}
\end{equation*}
$$

The energy of the carbon $2 p$ shell is the negative of the ionization energy of the carbon atom given by Eq. (10.123). Experimentally, the energy is [12]

$$
\begin{equation*}
E(C, 2 p \text { shell })=-E(\text { ionization } ; C)=-11.2603 \mathrm{eV} \tag{13.421}
\end{equation*}
$$

The $C 2 s$ atomic orbital (AO) combines with the $C 2 p$ AOs to form a single $2 s p^{3}$ hybridized orbital (HO) with the orbital arrangement:

$$
\begin{equation*}
 \tag{13.422}
\end{equation*}
$$

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the four electrons. The sum $E_{T}\left(C, 2 s p^{3}\right)$ of calculated energies of $C, C^{+}, C^{2+}$, and $C^{3+}$ from Eqs. (10.123), (10.113-10.114), (10.68), and (10.48), respectively, is:

$$
\begin{equation*}
E_{T}\left(C, 2 s p^{3}\right)=64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+11.27671 \mathrm{eV}=148.25751 \mathrm{eV} \tag{13.423}
\end{equation*}
$$

which agrees well with the sum of 148.02532 eV from the experimental [6] values. The orbital-angular-momentum interactions cancel such that the energy of the $E_{T}\left(C, 2 s p^{3}\right)$ is purely Coulombic. By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{2 s p^{3}}$ of the $C 2 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (10.102).

$$
\begin{align*}
r_{2 s p^{3}} & =\sum_{n=2}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 148.25751 \mathrm{eV})} \\
& =\frac{10 e^{2}}{8 \pi \varepsilon_{0}(e 148.25751 \mathrm{eV})}  \tag{13.424}\\
& =0.91771 a_{0}
\end{align*}
$$

Using Eqs. (10.102) and (13.424), the Coulombic energy $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{align*}
E_{\text {Coulomb }}\left(C, 2 s p^{3}\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{2 s p^{3}}} \\
& =\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.91771 a_{0}}=-14.82575 \mathrm{eV} \tag{13.425}
\end{align*}
$$

During hybridization, the spin-paired $2 s$ electrons are promoted to the $C 2 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (13.152) at the initial radius of the $2 s$ electrons. From Eq. (10.62) with $Z=6$, the radius $r_{3}$ of the $C 2 s$ shell is

$$
\begin{equation*}
r_{3}=0.84317 a_{0} \tag{13.426}
\end{equation*}
$$

Using Eqs. (13.152) and (13.426), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.84317 a_{0}\right)^{3}}=0.19086 \mathrm{eV} \tag{13.427}
\end{equation*}
$$

Using Eqs. (13.425) and (13.427), the energy $E\left(C, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{align*}
E\left(C, 2 s p^{3}\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}  \tag{13.428}\\
& =-14.82575 \mathrm{eV}+0.19086 \mathrm{eV}=-14.63489 \mathrm{eV}
\end{align*}
$$

The nitrogen atom's $2 p$-shell electron configuration given by Eq. (10.134) is the same as that of the $C 2 s p^{3}$ shell, and nitrogen's calculated energy of 14.61664 eV given by Eq. (10.143) is a close match with $E\left(C, 2 s p^{3}\right)$. Thus, the binding should be very similar except that four bonds to hydrogen can occur with carbon.

The carbon $C 2 s p^{3}$ electron combines with the $H 1 s$ electron to form a molecular orbital. The proton of the $H$ atom and the nucleus of the $C$ atom are along the internuclear axis and serve as the foci. Due to symmetry, the other $C$ electrons are equivalent to point charges at the origin. (See Eqs. (19-38) of Appendix II.) Thus, the energies in the CH MO involve only the $C 2 s p^{3}$ and $H 1 s$ electrons. The forces are determined by these energies.

As in the case of $H_{2}$, the MO is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into the $C 2 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C 2 s p^{3}$ shell. Thus, the MO surface comprises a prolate spheroid at the $H$ proton that is continuous with the $C 2 s p^{3}$ shell at the $C$ atom whose nucleus serves as the other focus. The energy of the $H_{2}$-type ellipsoidal MO is matched to that of the $C 2 s p^{3}$ shell. As in the case with $O H$ and $N H$, the linear combination of the $H_{2}$-type ellipsoidal MO with the $C 2 s p^{3} \mathrm{HO}$ must involve a $25 \%$ contribution from the $H_{2}$-type ellipsoidal MO to the $C 2 s p^{3}$ HO in order to match potential, kinetic, and orbital energy relationships. Thus, the CH MO must comprise $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO and a $C 2 s p^{3} \mathrm{HO}$ :

$$
\begin{equation*}
1 \mathrm{C} 2 \mathrm{sp}^{3}+0.75 \mathrm{H}_{2} \mathrm{MO} \rightarrow \mathrm{CH} \mathrm{MO} \tag{13.429}
\end{equation*}
$$

The force balance of the CH MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.429) and the energy matching condition between the hydrogen and $C 2 s p^{3} \mathrm{HO}$ components of the MO.

As in the case with OH (Eq. (13.57)), the $\mathrm{H}_{2}$-type ellipsoidal MO comprises $75 \%$ of the CH MO ; so, the electron charge density in Eq. (11.65) is given by $-0.75 e$. The force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin to each focus $c^{\prime}$ is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of the CH MO . Since the CH MO comprises a $\mathrm{H}_{2}$-typeellipsoidal MO that transitions to the $C 2 s p^{3} \mathrm{HO}$, the energy $E\left(C, 2 s p^{3}\right)$ in Eq. (13.428) adds to that of the $H_{2}$-type ellipsoidal MO to give the total energy of the $C H$ MO. From the energy equation and the relationship between the axes, the dimensions of the CH MO are solved.

The energy components of $V_{e}, V_{p}, T$, and $V_{m}$ are those of $H_{2}$ (Eqs. (11.207-11.212)) except that they are corrected for electron hybridization. Hybridization gives rise to the $C 2 s p^{3}$ HO-shell Coulombic energy $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ given by Eq. (13.425). To meet the equipotential condition of the union of the $H_{2}$-type-ellipsoidal-MO and the $C 2 s p^{3} \mathrm{HO}$, the electron energies are normalized by the ratio of 14.82575 eV , the magnitude of $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ given by Eq. (13.425), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). This
normalizes the energies to match that of the Coulombic energy alone to meet the energy matching condition of the CH MO under the influence of the proton and the $C$ nucleus. The hybridization energy factor $C_{C 2 s p^{3} H O}$ is

$$
\begin{equation*}
C_{C 2 s p^{3} H O}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} r_{2 s p^{3}}}}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} 0.91771 a_{0}}}=\frac{13.605804 \mathrm{eV}}{14.82575 \mathrm{eV}}=0.91771 \tag{13.430}
\end{equation*}
$$

The total energy $E_{T}(\mathrm{CH})$ of the CH MO is given by the sum of the energies of the orbitals, the $\mathrm{H}_{2}$-type ellipsoidal MO and the $C 2 s p^{3} \mathrm{HO}$, that form the hybridized $C H$ MO. $E_{T}(C H)$ follows from Eq. (13.74) for $O H$, but the energy of the $C 2 s p^{3}$ HO given by Eq. (13.428) is substituted for the energy of O and the $\mathrm{H}_{2}$-type-ellipsoidal-MO energies are those of $\mathrm{H}_{2}$ (Eqs. (11.207-11.212)) multiplied by the electron hybridization factor rather than by the factor of 0.75 :

$$
\begin{align*}
E_{T}(C H) & =E_{T}+E\left(C, 2 s p^{3}\right) \\
& =-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV} \tag{13.431}
\end{align*}
$$

To match the boundary condition that the total energy of the entire the $H_{2}$-type ellipsoidal MO is given by Eqs. (11.212) and (13.75), $E_{T}(\mathrm{CH})$ given by Eq. (13.431) is set equal to Eq. (13.75).

$$
\begin{equation*}
E_{T}(C H)=-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV}=-31.63536831 \mathrm{eV} \tag{13.432}
\end{equation*}
$$

From the energy relationship given by Eq. (13.432) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the CH MO can be solved.
Substitution of Eq. (13.60) into Eq. (13.432) gives:

$$
\begin{equation*}
\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right]=e 17.00048 \tag{13.433}
\end{equation*}
$$

The most convenient way to solve Eq. (13.433) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is:

$$
\begin{equation*}
a=1.67465 a_{0}=8.86186 \times 10^{-11} \mathrm{~m} \tag{13.434}
\end{equation*}
$$

Substitution of Eq. (13.434) into Eq. (13.60) gives:

$$
\begin{equation*}
c^{\prime}=1.05661 a_{0}=5.59136 \times 10^{-11} \mathrm{~m} \tag{13.435}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.435) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.11323 a_{0}=1.11827 \times 10^{-10} \mathrm{~m} \tag{13.436}
\end{equation*}
$$

The experimental bond distance is [14]:

$$
\begin{equation*}
2 c^{\prime}=1.1198 \times 10^{-10} \mathrm{~m} \tag{13.437}
\end{equation*}
$$

Substitution of Eqs. (13.434-13.435) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=1.29924 a_{0}=6.87527 \times 10^{-11} \mathrm{~m} \tag{13.438}
\end{equation*}
$$

Substitution of Eqs. (13.434-13.435) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.63095 \tag{13.439}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $C$ atom comprise the foci of the $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{2 s p^{3}}=0.91771 a_{0}$ is the radius of the $C 2 s p^{3}$ shell. Substitution of Eqs. (13.434-13.435) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=81.03^{\circ} \tag{13.440}
\end{equation*}
$$

Then, the angle $\theta_{C 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C 2 s p^{3} H O}=180^{\circ}-81.03^{\circ}=98.97^{\circ} \tag{13.441}
\end{equation*}
$$

as shown in Figure 13.9.

Figure 13.9. The cross section of the $C H$ MO showing the axes, angles, and point of intersection of the $H_{2}$-type ellipsoidal MO with the $\mathrm{C} 2 s p^{3} \mathrm{HO}$. The continuation of the $\mathrm{H}_{2}$-type-ellipsoidal-MO basis element beyond the intersection point with the $C 2 s p^{3}$ shell is shown as dashed since it only serves to solve the energy match with the $C 2 s p^{3}$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of the intersection point. The actual charge density is shown by the solid lines. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}:$ internuclear distance, $d_{1}: d_{H_{2} M O}$, $\theta_{1}: \theta_{C 2 s p^{3} H O}, d_{2}: d_{C 2 s p^{3} H O}$, and $R: r_{2 s p^{3}}$.

The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{2 s p^{3}} \sin \theta_{C 2 s p^{3} H O}=0.91771 a_{0} \sin \theta_{C 2 s p^{3} H O}=b \sin \theta_{H_{2} M O} \tag{13.442}
\end{equation*}
$$

such that

$$
\begin{align*}
\theta_{H_{2} M O} & =\sin ^{-1} \frac{0.91771 a_{0} \sin \theta_{C 2 s p^{3} H O}}{b}  \tag{13.443}\\
& =\sin ^{-1} \frac{0.91771 a_{0} \sin 98.97^{\circ}}{b}
\end{align*}
$$

with the use of Eq. (13.441). Substitution of Eq. (13.438) into Eq. (13.443) gives:

$$
\begin{equation*}
\theta_{H_{2} M O}=44.24^{\circ} \tag{13.444}
\end{equation*}
$$

Then, the distance $d_{\mathrm{H}_{2} M O}$ along the internuclear axis from the origin of $\mathrm{H}_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by

$$
\begin{equation*}
d_{\mathrm{H}_{2} \mathrm{MO}}=a \cos \theta_{\mathrm{H}_{2} \mathrm{MO}} \tag{13.445}
\end{equation*}
$$

Substitution of Eqs. (13.434) and (13.444) into Eq. (13.445) gives:

$$
\begin{equation*}
d_{H_{2} M O}=1.19968 a_{0}=6.34845 \times 10^{-11} \mathrm{~m} \tag{13.446}
\end{equation*}
$$

The distance $d_{C 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C 2 s p^{3} \mathrm{HO}}=d_{\mathrm{H}_{2} \mathrm{MO}}-c^{\prime} \tag{13.447}
\end{equation*}
$$

Substitution of Eqs. (13.435) and (13.446) into Eq. (13.447) gives:

$$
\begin{equation*}
d_{C 2 s p^{3} H O}=0.14307 a_{0}=7.57090 \times 10^{-12} \mathrm{~m} \tag{13.448}
\end{equation*}
$$

As shown in Eq. (13.429), the uniform charge-density in the $C 2 s p^{3} \mathrm{HO}$ is increased by a factor of 0.25 and the $H$-atom density is decreased by a factor of 0.25 . Using the orbital composition of $C H$ (Eq. (13.429)), the radii of $C 1 s=0.17113 a_{0}$ (Eq. (10.51)) and $C 2 s p^{3}=0.91771 a_{0}$ (Eq. (13.424)) shells, and the parameters of the $C H$ MO given by Eqs. (13.3-13.4), (13.43413.436), and (13.438-13.448), the dimensional diagram and charge-density of the CH MO comprising the linear combination of the $H_{2}$-type ellipsoidal MO and the $C 2 s p^{3} \mathrm{HO}$ according to Eq. (13.429) are shown in Figures 13.9 and 13.10, respectively.

Figure 13.10. $C H$ MO comprising the superposition of the $H_{2}$-type ellipsoidal MO and the $C 2 s p^{3} \mathrm{HO}$ with a relative charge-density of 0.75 to 1.25 ; otherwise, the $C 2 s p^{3} \mathrm{HO}$ is unchanged. (A) Side-on, color scale, translucent view of the chargedensity of the CH MO . The ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C 2 s p^{3} \mathrm{HO}$, the $C 2 s p^{3} \mathrm{HO}$ shell, $C 1 s$ shell, and the nuclei (red, not to scale) are shown. (B) Cut-away view showing the inner most $C 1 s$ shell, and moving radially, the $C 2 s p^{3}$ shell, and the $H_{2}$-type ellipsoidal MO that transitions to the $C 2 s p^{3} \mathrm{HO}$.

## ENERGIES OF $C H$

The energies of CH are given by the substitution of the semiprincipal axes (Eqs. (13.434-13.435) and (13.438)) into the energy equations (Eq. (13.431) and Eqs. (11.207-11.211)) that are corrected for electron hybridization using Eq. (13.430).

$$
\begin{align*}
& V_{e}=(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-35.12015 \mathrm{eV}  \tag{13.449}\\
& V_{p}=\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=12.87680 \mathrm{eV}  \tag{13.450}\\
& T=(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=10.48582 \mathrm{eV}  \tag{13.451}\\
& V_{m}=(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-5.24291 \mathrm{eV}  \tag{13.452}\\
& E_{T}(C H)=-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV}=-31.63533 \mathrm{eV} \tag{13.453}
\end{align*}
$$

where $E_{T}(\mathrm{CH})$ is given by Eq. (13.431) which is reiteratively matched to Eq. (13.75) within five-significant-figure round-off error.

## VIBRATION AND ROTATION OF $C H$

The vibrational energy of CH may be solved in the same manner as that of OH and NH except that the force between the electrons and the foci given by Eq. (13.102) is doubled due to electron hybridization of the two shells of carbon after Eq. (11.141). From Eqs. (13.102-13.106) with the substitution of the CH parameters, the angular frequency of the oscillation is

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} b^{3}}-\frac{e^{2}}{8 \pi \varepsilon_{0}\left(2 c^{\prime}\right)^{3}}}{\mu}}=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0}\left(1.29924 a_{0}\right)^{3}}-\frac{e^{2}}{\frac{12}{13} m_{p}}}{\frac{4 \pi \varepsilon_{0}\left(2.11323 a_{0}\right)^{3}}{}}}=5.39828 \times 10^{14} \mathrm{rad} / \mathrm{s} \tag{13.454}
\end{equation*}
$$

where $b$ is given by Eq. (13.438), $2 c^{\prime}$ is given by Eq. (13.436), and the reduced mass of ${ }^{12} \mathrm{CH}$ is given by:

$$
\begin{equation*}
\mu_{1^{2} C H}=\frac{m_{1} m_{2}}{m_{1}+m_{2}}=\frac{(1)(12)}{1+12} m_{p} \tag{13.455}
\end{equation*}
$$

where $m_{p}$ is the proton mass. Thus, during bond formation, the perturbation of the orbit determined by an inverse-squared force results in simple harmonic oscillatory motion of the orbit, and the corresponding frequency, $\omega(0)$, for ${ }^{12} \mathrm{CH}$ given by Eqs. (11.136), (11.148), and (13.454) is:

$$
\begin{equation*}
\omega(0)=\sqrt{\frac{k(0)}{\mu}}=\sqrt{\frac{449.94 \mathrm{Nm}^{-1}}{\mu}}=5.39828 \times 10^{14} \text { radians } / \mathrm{s} \tag{13.456}
\end{equation*}
$$

where the reduced nuclear mass of ${ }^{12} \mathrm{CH}$ is given by Eq. (13.455) and the spring constant, $k(0)$, given by Eqs. (11.136) and (13.454) is:

$$
\begin{equation*}
k(0)=449.94 \mathrm{Nm}^{-1} \tag{13.457}
\end{equation*}
$$

The ${ }^{12} \mathrm{CH}$ transition-state vibrational energy, $E_{\text {vib }}(0)$, given by Planck's equation (Eq. (11.127)) is:

$$
\begin{equation*}
E_{v i b}(0)=\hbar \omega=\hbar 5.39828 \times 10^{14} \mathrm{rad} / \mathrm{s}=0.35532 \mathrm{eV}=2865.86 \mathrm{~cm}^{-1} \tag{13.458}
\end{equation*}
$$

$\omega_{e}$, from the experimental curve fit of the vibrational energies of ${ }^{12} \mathrm{CH}$ is [14] :

$$
\begin{equation*}
\omega_{e}=2861.6 \mathrm{~cm}^{-1} \tag{13.459}
\end{equation*}
$$

Using Eqs. (13.112-13.118) with $E_{v i b}(0)$ given by Eq. (13.458) and $D_{0}$ given by Eq. (13.488), the ${ }^{12} \mathrm{CH} \quad v=1 \rightarrow v=0$ vibrational energy, $E_{v i b}(1)$ is:

$$
\begin{equation*}
E_{v i b}(1)=0.33879 \mathrm{eV} \quad\left(2732.61 \mathrm{~cm}^{-1}\right) \tag{13.460}
\end{equation*}
$$

The experimental vibrational energy of ${ }^{12} \mathrm{CH}$ using $\omega_{e}$ and $\omega_{e} x_{e}$ [14] according to K\&P [15] is:

$$
\begin{equation*}
E_{v i b}(1)=0.33885 \mathrm{eV} \quad\left(2733 \mathrm{~cm}^{-1}\right) \tag{13.461}
\end{equation*}
$$

Using Eq. (13.113) with $E_{v i b}(1)$ given by Eq. (13.460) and $D_{0}$ given by Eq. (13.488), the anharmonic perturbation term, $\omega_{0} x_{0}$, of ${ }^{12} \mathrm{CH}$ is:

$$
\begin{equation*}
\omega_{0} x_{0}=66.624 \mathrm{~cm}^{-1} \tag{13.462}
\end{equation*}
$$

The experimental anharmonic perturbation term, $\omega_{0} x_{0}$, of ${ }^{12} \mathrm{CH}$ [14] is:

$$
\begin{equation*}
\omega_{0} x_{0}=64.3 \mathrm{~cm}^{-1} \tag{13.463}
\end{equation*}
$$

The vibrational energies of successive states are given by Eqs. (13.458), (13.112), and (13.462).
Using $b$ given by Eq. (13.438), $2 c^{\prime}$ given by Eq. (13.436), $D_{0}$ given by Eq. (13.490), and the reduced nuclear mass of ${ }^{12} C D$ given by:

$$
\begin{equation*}
\mu_{\mathrm{1}^{2} C D}=\frac{m_{1} m_{2}}{m_{1}+m_{2}}=\frac{(2)(12)}{2+12} m_{p} \tag{13.464}
\end{equation*}
$$

where $m_{p}$ is the proton mass, the corresponding parameters for deuterium carbide ${ }^{12} C D$ (Eqs. (13.102-13.121)) are:

$$
\begin{align*}
& \omega(0)=\sqrt{\frac{k(0)}{\mu}}=\sqrt{\frac{449.94 \mathrm{Nm}^{-1}}{\mu}}=3.96126 \times 10^{14} \text { radians } / \mathrm{s}  \tag{13.465}\\
& k(0)=449.94 \mathrm{Nm}^{-1}  \tag{13.466}\\
& E_{\text {vib }}(0)=\hbar \omega=\hbar 3.96126 \times 10^{14} \mathrm{rad} / \mathrm{s}=0.26074 \mathrm{eV}=2102.97 \mathrm{~cm}^{-1}  \tag{13.467}\\
& E_{\text {vib }}(1)=0.25173 \mathrm{eV} \quad\left(2030.30 \mathrm{~cm}^{-1}\right)  \tag{13.468}\\
& \omega_{0} x_{0}=36.335 \mathrm{~cm}^{-1} \tag{13.469}
\end{align*}
$$

$\omega_{e}$, from the experimental curve fit of the vibrational energies of ${ }^{12} C D$ is [14] :

$$
\begin{equation*}
\omega_{e}=2101.0 \mathrm{~cm}^{-1} \tag{13.470}
\end{equation*}
$$

The experimental vibrational energy of ${ }^{12} C D$ using $\omega_{e}$ and $\omega_{e} x_{e}$ [14] according to K\&P [15] is:

$$
\begin{equation*}
E_{v i b}(1)=0.25189 \mathrm{eV} \quad\left(2031.6 \mathrm{~cm}^{-1}\right) \tag{13.471}
\end{equation*}
$$

and the experimental anharmonic perturbation term, $\omega_{0} x_{0}$, of ${ }^{12} C D$ is [14] :

$$
\begin{equation*}
\omega_{0} x_{0}=34.7 \mathrm{~cm}^{-1} \tag{13.472}
\end{equation*}
$$

which match the predictions given by Eqs. (13.467), (13.468) and (13.469), respectively.
Using Eqs. (13.133-13.134) and the internuclear distance, $r=2 c^{\prime}$, and reduced mass of ${ }^{12} \mathrm{CH}$ given by Eqs. (13.436) and (13.455), respectively, the corresponding $B_{e}$ is:

$$
\begin{equation*}
B_{e}=14.498 \mathrm{~cm}^{-1} \tag{13.473}
\end{equation*}
$$

The experimental $B_{e}$ rotational parameter of ${ }^{12} \mathrm{CH}$ is [14]:

$$
\begin{equation*}
B_{e}=14.457 \mathrm{~cm}^{-1} \tag{13.474}
\end{equation*}
$$

Using the internuclear distance, $r=2 c^{\prime}$, and reduced mass of ${ }^{12} C D$ given by Eqs. (13.436) and (13.464), respectively, the corresponding $B_{e}$ is:

$$
\begin{equation*}
B_{e}=7.807 \mathrm{~cm}^{-1} \tag{13.475}
\end{equation*}
$$

The experimental $B_{e}$ rotational parameter of ${ }^{12} C D$ is [14]:

$$
\begin{equation*}
B_{e}=7.808 \mathrm{~cm}^{-1} \tag{13.476}
\end{equation*}
$$

## THE DOPPLER ENERGY TERMS OF ${ }^{12} \mathrm{CH}$ AND ${ }^{12} \mathrm{CD}$

The equations of the radiation reaction force of hydrogen and deuterium carbide are the same as those of the corresponding hydroxyl and hydrogen nitride radicals with the substitution of the hydrogen and deuterium carbide parameters. Using Eqs. (11.136) and (13.140-13.142), the angular frequency of the reentrant oscillation in the transition state is

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=2.41759 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{13.477}
\end{equation*}
$$

where $b$ is given by Eq. (13.438). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 2.41759 \times 10^{16} \mathrm{rad} / \mathrm{s}=15.91299 \mathrm{eV} \tag{13.478}
\end{equation*}
$$

In Eq. (11.181), substitution of the total energy of $C H, E_{T}(C H)$, (Eq. (13.432)) for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.478) for $\bar{E}_{K}$ gives the Doppler energy of the electrons for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-31.63537 \mathrm{eV} \sqrt{\frac{2 e(15.91299 \mathrm{eV})}{m_{e} c^{2}}}=-0.24966 \mathrm{eV} \tag{13.479}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of CH due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.479) and $\bar{E}_{K v i b}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of CH . The experimental ${ }^{12} \mathrm{CH} \omega_{e}$ is $2861.6 \mathrm{~cm}^{-1}(0.35480 \mathrm{eV})$ [14] which matches the predicted $\omega_{e}$ of $2865.86 \mathrm{~cm}^{-1}(0.35532 \mathrm{eV})$ given by Eq. (13.458). Using the predicted $\omega_{e}$ for $\bar{E}_{\text {Kvib }}$ of the transition state, $\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}\right)$ is:

$$
\begin{align*}
& \bar{E}_{o s c}\left({ }^{12} \mathrm{CH}\right)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.480}\\
& \bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}\right)=-0.24966 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})=-0.07200 \mathrm{eV} \tag{13.481}
\end{align*}
$$

The experimental ${ }^{12} C D \omega_{e}$ is $2101.0 \mathrm{~cm}^{-1}(0.26049 \mathrm{eV})$ [14] which matches the predicted $\omega_{e}$ of $2102.97 \mathrm{~cm}^{-1}(0.26074 \mathrm{eV})$ given by Eq. (13.467). Using Eq. (13.479) and the predicted $\omega_{e}$ for $\bar{E}_{\text {Kvib }}$ of the transition state, $\bar{E}_{\text {osc }}\left({ }^{12} C D\right)$ is:

$$
\begin{equation*}
\bar{E}_{\text {osc }}\left({ }^{12} C D\right)=-0.24966 \mathrm{eV}+\frac{1}{2}(0.26074 \mathrm{eV})=-0.11929 \mathrm{eV} \tag{13.482}
\end{equation*}
$$

## TOTAL AND BOND ENERGIES OF ${ }^{12} \mathrm{CH}$ AND ${ }^{12} \mathrm{CD}$

$E_{T+o s c}\left({ }^{12} \mathrm{CH}\right)$, the total energy of the ${ }^{12} \mathrm{CH}$ radical including the Doppler term, is given by the sum of $E_{T}(\mathrm{CH})$ (Eq. (13.432)) and $\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}\right)$ given by Eq. (13.481):

$$
\begin{align*}
E_{T+o s c}\left({ }^{12} \mathrm{CH}\right) & =V_{e}+T+V_{m}+V_{p}+E\left(C, 2 s p^{3}\right)+\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}\right)=E_{T}(\mathrm{CH})+\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}\right)  \tag{13.483}\\
E_{T+o s c}\left({ }^{12} \mathrm{CH}\right) & =\left\{\left(\begin{array}{l}
\left(\frac{-e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV}\right) \\
\left.1+\sqrt{\frac{\frac{3}{\frac{e^{2}}{4} \frac{4 \pi \varepsilon_{0} b^{3}}{m_{e}}}}{m_{e} c^{2}}}\right)+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}
\end{array}\right\}\right.  \tag{13.484}\\
& =-31.63537 \mathrm{eV}-0.24966 \mathrm{eV}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}
\end{align*}
$$

From Eqs. (13.480-13.481) and (13.483-13.484), the total energy of ${ }^{12} \mathrm{CH}$ is:

$$
\begin{align*}
E_{T+\text { osc }}\left({ }^{12} \mathrm{CH}\right) & =-31.63537 \mathrm{eV}+\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}\right) \\
& =-31.63537 \mathrm{eV}-0.24966 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})  \tag{13.485}\\
& =-31.70737 \mathrm{eV}
\end{align*}
$$

where the predicted $\omega_{e}$ (Eq. (13.458)) was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term. $E_{T+o s c}\left({ }^{12} C D\right)$, the total energy of ${ }^{12} C D$ including the Doppler term, is given by the sum of $E_{T}(C D)=E_{T}(C H)$ (Eq. (13.432)) and $\bar{E}_{\text {osc }}\left({ }^{12} C D\right)$ given by Eq. (13.482).

$$
\begin{align*}
E_{T+o s c}\left({ }^{12} C D\right) & =-31.63537 \mathrm{eV}+\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CD}\right) \\
& =-31.63537 \mathrm{eV}-0.24966 \mathrm{eV}+\frac{1}{2}(0.26074 \mathrm{eV})  \tag{13.486}\\
& =-31.75462 \mathrm{eV}
\end{align*}
$$

where the predicted $\omega_{e}$ (Eq. (13.467)) was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The $C H$ bond dissociation energy, $E_{D}\left({ }^{12} \mathrm{CH}\right)$, is given by the sum of the total energies of the $C 2 s p^{3} \mathrm{HO}$ and the hydrogen atom minus $E_{T+o s c}\left({ }^{12} \mathrm{CH}\right)^{3}$ :

$$
\begin{equation*}
E_{D}\left({ }^{12} \mathrm{CH}\right)=E\left(C, 2 s p^{3}\right)+E(H)-E_{T+o s c}\left({ }^{12} \mathrm{CH}\right) \tag{13.487}
\end{equation*}
$$

$E\left(C, 2 s p^{3}\right)$ is given by Eq. (13.428), and $E_{D}(H)$ is given by Eq. (13.154). Thus, the ${ }^{12} C H$ bond dissociation energy, $E_{D}\left({ }^{12} \mathrm{CH}\right)$, given by Eqs. (13.154), (13.428), (13.485), and (13.487) is:

$$
\begin{align*}
E_{D}\left({ }^{12} \mathrm{CH}\right) & =-(14.63489 \mathrm{eV}+13.59844 \mathrm{eV})-E_{T+o s c}(C H) \\
& =-28.23333 \mathrm{eV}-(-31.70737 \mathrm{eV})  \tag{13.488}\\
& =3.47404 \mathrm{eV}
\end{align*}
$$

The experimental ${ }^{12} \mathrm{CH}$ bond dissociation energy is [14]:

$$
\begin{equation*}
E_{D}\left({ }^{12} \mathrm{CH}\right)=3.47 \mathrm{eV} \tag{13.489}
\end{equation*}
$$

which is a close match to that of $N H$ as predicted based on the match between the $N$ and $C 2 s p^{3} \mathrm{HO}$ energies and electron configurations.

The ${ }^{12} C D$ bond dissociation energy, $E_{D}\left({ }^{12} C D\right)$, is given by the sum of the total energies of the $C 2 s p{ }^{3}$ HO and the deuterium atom minus $E_{T+\text { osc }}(C D)$ :

$$
\begin{equation*}
E_{D}\left({ }^{12} C D\right)=E\left(C, 2 s p^{3}\right)+E(D)-E_{T+o s c}\left({ }^{12} C D\right) \tag{13.490}
\end{equation*}
$$

$E\left(C, 2 s p^{3}\right)$ is given by Eq. (13.428), and $E_{D}(D)$ is given by Eq. (13.155). Thus, the ${ }^{12} C D$ bond dissociation energy, $E_{D}\left({ }^{12} C D\right)$, given by Eqs. (13.155), (13.428), (13.486), and (13.490) is:

$$
\begin{align*}
E_{D}\left({ }^{12} C D\right) & =-(14.63489 \mathrm{eV}+13.603 \mathrm{eV})-E_{T+o s c}\left({ }^{12} \mathrm{CD}\right) \\
& =-28.23789 \mathrm{eV}-(-31.75462 \mathrm{eV})  \tag{13.491}\\
& =3.51673 \mathrm{eV}
\end{align*}
$$

The experimental ${ }^{12} C D$ bond dissociation energy is [14]:

$$
\begin{equation*}
E_{D}\left({ }^{12} C D\right)=3.52 \mathrm{eV} \tag{13.492}
\end{equation*}
$$

The results of the determination of bond parameters of $C H$ and $C D$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

[^38]
## DIHYDROGEN CARBIDE ( $\mathrm{CH}_{2}$ )

The dihydrogen carbide radical $\mathrm{CH}_{2}$ is formed by the reaction of a hydrogen atom with a hydrogen carbide radical:

$$
\begin{equation*}
\mathrm{CH}+\mathrm{H} \rightarrow \mathrm{CH}_{2} \tag{13.493}
\end{equation*}
$$

$\mathrm{CH}_{2}$ can be solved using the same principles as those used to solve $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{NH}_{2}$ with the exception that the carbon $2 s$ and
$2 p$ shells hybridize to form a single $2 s p^{3}$ shell as an energy minimum. Two diatomic molecular orbitals (MOs) developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section serve as basis functions in a linear combination with two carbon $2 s p^{3}$ hybridized orbitals ( HOs ) to form the MO of $\mathrm{CH}_{2}$. The solution is very similar to that of CH except that there are two CH bonds in $\mathrm{CH}_{2}$.

## FORCE BALANCE OF $\mathrm{CH}_{2}$

$\mathrm{CH}_{2}$ comprises two chemical bonds between carbon and hydrogen atoms. Each $\mathrm{C}-\mathrm{H}$ bond comprises two spin-paired electrons with one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom. Each $H$-atom electron forms a $\mathrm{H}_{2}$-type ellipsoidal MO with an unpaired C -atom electrons. However, such a bond is not possible with the outer two $C$ electrons in their ground state since the resulting $H_{2}$-type ellipsoidal MO would have a shorter internuclear distance than the radius of the carbon $2 p$ shell, which is not energetically stable. Thus, when bonding the carbon $2 s$ and $2 p$ shells hybridize to form a single $2 s p^{3}$ shell as an energy minimum. The electron configuration and the energy, $E\left(C, 2 s p^{3}\right)$, of the $C 2 s p^{3}$ shell is given by Eqs. (13.422), and (13.428), respectively.

For each $C-H$ bond, a $C 2 s p^{3}$ electron combines with the $H 1 s$ electron to form a molecular orbital. The proton of the $H$ atom and the nucleus of the $C$ atom are along each internuclear axis and serve as the foci. As in the case of $H_{2}$, each of the two $C-H$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into the $C 2 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C 2 s p^{3}$ shell since it is energetically unfavorable. Thus, each MO surface comprises a prolate spheroid at the $H$ proton that is continuous with the $C 2 s p^{3}$ shell at the $C$ atom whose nucleus serves as the other focus. The radius and the energy of the $C 2 s p^{3}$ shell are unchanged with bond formation. The central paramagnetic force due to spin of each $\mathrm{C}-\mathrm{H}$ bond is provided by the spin-pairing force of the $\mathrm{CH}_{2}$ MO that has the symmetry of an $s$ orbital that superimposes with the $C 2 s p^{3}$ orbitals such that the corresponding angular momenta are unchanged.

The energies in the $\mathrm{CH}_{2}$ MO involve only each $\mathrm{C} 2 \mathrm{sp}^{3}$ and each H 1 s electron with the formation of each $\mathrm{C}-\mathrm{H}$ bond. The sum of the energies of the $\mathrm{H}_{2}$-type ellipsoidal MOs is matched to that of the $\mathrm{C} 2 s p^{3}$ shell. As in the cases of $\mathrm{OH}, \mathrm{H}_{2} \mathrm{O}$, $\mathrm{NH}, \mathrm{NH}_{2}, \mathrm{NH}_{3}$, and CH the linear combination of each $\mathrm{H}_{2}$-type ellipsoidal MO with the $\mathrm{C} 2 s p^{3} \mathrm{HO}$ must involve a $25 \%$ contribution from the $H_{2}$-type ellipsoidal MO to the $C 2 s p^{3} \mathrm{HO}$ in order to match potential, kinetic, and orbital energy relationships. Thus, the $\mathrm{CH}_{2}$ MO must comprise two $\mathrm{C}-\mathrm{H}$ bonds with each comprising $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO and a $C 2 s p^{3} \mathrm{HO}$ :

$$
\begin{equation*}
\left[1 \mathrm{C} 2 s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO}\right]+\left[1 \mathrm{C} 2 s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO}\right] \rightarrow \mathrm{CH}_{2} \mathrm{MO} \tag{13.494}
\end{equation*}
$$

The force balance of the $\mathrm{CH}_{2} \mathrm{MO}$ is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.494) and the energy matching condition between the hydrogen and $C 2 s p^{3} \mathrm{HO}$ components of the MO.

The force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ of the each $H_{2}$-type-ellipsoidal-MO component of the $\mathrm{CH}_{2} \mathrm{MO}$ in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $\mathrm{C}-\mathrm{H}$-bond MO to each focus $c^{\prime}$ is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $\mathrm{C}-\mathrm{H}$ bond MO. Since each of the two prolate spheroidal $\mathrm{C}-\mathrm{H}$-bond MOs comprises a $H_{2}$-type-ellipsoidal MO that transitions to the $C 2 s p^{3} \mathrm{HO}$, the energy $E\left(C, 2 s p^{3}\right)$ in Eq. (13.428) adds to that of the two corresponding $H_{2}$-type ellipsoidal MOs to give the total energy of the $\mathrm{CH}_{2} \mathrm{MO}$. From the energy equation and the relationship between the axes, the dimensions of the $\mathrm{CH}_{2}$ MO are solved.

The energy components of $V_{e}, V_{p}, T$, and $V_{m}$ are twice those of $C H$ corresponding to the two $C-H$ bonds. Since each prolate spheroidal $H_{2}$-type MO transitions to the $C 2 s p^{3} \mathrm{HO}$ and the energy of the $C 2 s p^{3}$ shell must remain constant and equal to the $E\left(C, 2 s p^{3}\right)$ given by Eq. (13.428), the total energy $E_{T}\left(\mathrm{CH}_{2}\right)$ of the $\mathrm{CH}_{2} \mathrm{MO}$ is given by the sum of the energies
of the orbitals corresponding to the composition of the linear combination of the $C 2 s p^{3} \mathrm{HO}$ and the two $\mathrm{H}_{2}$-type ellipsoidal MOs that forms the $\mathrm{CH}_{2} \mathrm{MO}$ as given by Eq. (13.494). Using Eq. (13.431), $E_{T}\left(\mathrm{CH}_{2}\right)$ is given by:

$$
\begin{equation*}
E_{T}\left(C H_{2}\right)=E_{T}+E\left(C, 2 s p^{3}\right)=-\frac{e^{2}}{4 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV} \tag{13.495}
\end{equation*}
$$

The two hydrogen atoms and the hybridized carbon atom can achieve an energy minimum as a linear combination of two $\mathrm{H}_{2}$ type ellipsoidal MOs each having the proton and the carbon nucleus as the foci. Hybridization gives rise to the $C 2 s p^{3}$ HO-shell Coulombic energy $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ given by Eq. (13.425). To meet the equipotential condition of the union of the $H_{2}$-type-ellipsoidal-MO and the $C 2 s p^{3} \mathrm{HO}$, the electron energies in Eq. (13.495) were normalized by the ratio of 14.82575 eV , the magnitude of $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ given by Eq. (13.425), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). The factor given by Eq. (13.430) normalized the energies to match that of the Coulombic energy alone to meet the energy matching condition of each $C-H$-bond MO under the influence of the proton and the $C$ nucleus. Each $C-H$-bond MO comprises the same $C 2 s p^{3}$ shell having its energy normalized to that of the Coulombic energy between the electron and a charge of $+e$ at the carbon focus of the $\mathrm{CH}_{2} \mathrm{MO}$. Thus, the energy of the $\mathrm{CH}_{2} \mathrm{MO}$ is also given by the sum of that of the two $H_{2}$-type ellipsoidal MOs given by Eq. (11.212) minus the Coulombic energy, $E_{\text {Coulomb }}(H)=-13.605804 \mathrm{eV}$, of the redundant $+e$ of the linear combination:

$$
\begin{align*}
E_{T}\left(2 H_{2}-H\right) & =-\frac{e^{2}}{4 \pi \varepsilon_{0} a_{0}}\left[\left(2 \sqrt{2}-\sqrt{2}+\frac{\sqrt{2}}{2}\right) \ln \frac{\sqrt{2}+1}{\sqrt{2}-1}-\sqrt{2}\right]-E_{\text {Coulomb }}(H) \\
& =2(-31.63536831 \mathrm{eV})-(-13.605804 \mathrm{eV})  \tag{13.496}\\
& =-49.66493 \mathrm{eV}
\end{align*}
$$

$E_{T}\left(\mathrm{CH}_{2}\right)$ given by Eq. (13.495) is set equal to two times the energy of the $H_{2}$-type ellipsoidal MO minus the Coulombic energy of $H$ given by Eq. (13.496):

$$
\begin{align*}
E_{T}\left(C H_{2}\right) & =-\frac{e^{2}}{4 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV}  \tag{13.497}\\
& =-49.66493 \mathrm{eV}
\end{align*}
$$

From the energy relationship given by Eq. (13.497) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the $\mathrm{CH}_{2} \mathrm{MO}$ can be solved.

Substitution of Eq. (13.60) into Eq. (13.497) gives:

$$
\begin{equation*}
\frac{e^{2}}{4 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right]=e 35.03004 \tag{13.498}
\end{equation*}
$$

The most convenient way to solve Eq. (13.498) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is

$$
\begin{equation*}
a=1.64010 a_{0}=8.67903 \times 10^{-11} \mathrm{~m} \tag{13.499}
\end{equation*}
$$

Substitution of Eq. (13.499) into Eq. (13.60) gives:

$$
\begin{equation*}
c^{\prime}=1.04566 a_{0}=5.53338 \times 10^{-11} \mathrm{~m} \tag{13.500}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.500) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.09132 a_{0}=1.10668 \times 10^{-10} \mathrm{~m} \tag{13.501}
\end{equation*}
$$

The experimental bond distance is [38]:

$$
\begin{equation*}
2 c^{\prime}=1.111 \times 10^{-10} \mathrm{~m} \tag{13.502}
\end{equation*}
$$

Substitution of Eqs. (13.499-13.500) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=1.26354 a_{0}=6.68635 \times 10^{-11} \mathrm{~m} \tag{13.503}
\end{equation*}
$$

Substitution of Eqs. (13.499-13.500) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.63756 \tag{13.504}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $C$ atom comprise the foci of each $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of each $H_{2}$-type ellipsoidal MO and the $C 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95), (13.261-
13.270), and (13.440-13.448). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{2 s p^{3}}=0.91771 a_{0}$ is the radius of the $C 2 s p^{3}$ shell. Substitution of Eqs. (13.499-13.500) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=84.54^{\circ} \tag{13.505}
\end{equation*}
$$

Then, the angle $\theta_{C 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C 2 s p^{3} H O}=180^{\circ}-84.54^{\circ}=95.46^{\circ} \tag{13.506}
\end{equation*}
$$

as shown in Figure 13.9. The parametric angle $\theta_{\mathrm{H}_{2} \mathrm{MO}}$ given by Eqs. (13.442-13.443), (13.503), and (13.506) is:

$$
\begin{equation*}
\theta_{H_{2} M O}=46.30^{\circ} \tag{13.507}
\end{equation*}
$$

Then, the distance $d_{\mathrm{H}_{2} \mathrm{MO}}$ along the internuclear axis from the origin of $\mathrm{H}_{2}$-type ellipsoidal MO to the point of intersection of the orbitals given by Eqs. (13.445), (13.499), and (13.507) is:

$$
\begin{align*}
d_{H_{2} M O} & =1.13305 a_{0}  \tag{13.508}\\
& =5.99585 \times 10^{-11} \mathrm{~m}
\end{align*}
$$

The distance $d_{C 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals given by Eqs. (13.447), (13.500), and (13.508) is:

$$
\begin{align*}
d_{C 2 s p^{3} H O} & =0.08739 a_{0}  \tag{13.509}\\
& =4.62472 \times 10^{-12} \mathrm{~m}
\end{align*}
$$

As shown in Eq. (13.494), the uniform charge-density in the $C 2 s p^{3} \mathrm{HO}$ is increased by a factor of 0.25 and the $H$-atom density is decreased by a factor of 0.25 for by each $\mathrm{C}-\mathrm{H}$ bond. Using the orbital composition of $\mathrm{CH}_{2}$ (Eq. (13.494)), the radii of $C 1 s=0.17113 a_{0}$ (Eq. (10.51)) and $C 2 s p^{3}=0.91771 a_{0}$ (Eq. (13.424)) shells, and the parameters of the $\mathrm{CH}_{2}$ MO given by Eqs. (13.3-13.4), (13.499-13.501), and (13.503-13.509), the charge-density of the $\mathrm{CH}_{2} \mathrm{MO}$ comprising the linear combination of two $C-H$-bond MOs is shown in Figure 13.11. Each $C-H$-bond MO comprises a $H_{2}$-type ellipsoidal MO and a $C 2 s p^{3}$ HO having the dimensional diagram shown in Figure 13.9.

Figure 13.11. $\mathrm{CH}_{2} \mathrm{MO}$ comprising the linear combination of two $\mathrm{C}-H$-bond MOs. Each $\mathrm{C}-H$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and a $C 2 s p^{3} \mathrm{HO}$ with a relative charge-density of 0.75 to 1.25 ; otherwise, the $C 2 s p^{3}$ HO shell is unchanged. (A) Color scale, translucent view of the charge-density of the $\mathrm{CH}_{2} \mathrm{MO}$ from the top. For each $\mathrm{C}-\mathrm{H}$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C 2 s p^{3} \mathrm{HO}$, the $C 2 s p^{3} \mathrm{HO}$ shell, $C 1 s$ shell, and the nuclei (red, not to scale) are shown. (B) Cut-away view showing the inner most $C 1 s$ shell, and moving radially, the $C 2 s p^{3}$ shell, and the $H_{2}$-type ellipsoidal MO that transitions to the $C 2 s p^{3} \mathrm{HO}$ for each $C-H$ bond. Bisector current not shown.

## ENERGIES OF $\mathrm{CH}_{2}$

The energies of $\mathrm{CH}_{2}$ are two times those of CH and are given by the substitution of the semiprincipal axes (Eqs. (13.499$13.500)$ and (13.503)) into the energy equations Eq. (13.495) and (Eqs. (13.449-13.452)) that are multiplied by two:

$$
\begin{align*}
& V_{e}=(0.91771) \frac{-2 e^{2}}{4 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-72.03287 \mathrm{eV}  \tag{13.510}\\
& V_{p}=\frac{e^{2}}{4 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=26.02344 \mathrm{eV}  \tag{13.511}\\
& T=(0.91771) \frac{\hbar^{2}}{m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=21.95990 \mathrm{eV}  \tag{13.512}\\
& V_{m}=(0.91771) \frac{-\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-10.97995 \mathrm{eV}  \tag{13.513}\\
& E_{T}\left(C H_{2}\right)=-\frac{e^{2}}{4 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV}=-49.66437 \mathrm{eV} \tag{13.514}
\end{align*}
$$

where $E_{T}\left(\mathrm{CH}_{2}\right)$ is given by Eq. (13.495) which is reiteratively matched to Eq. (13.496) within five-significant-figure round-off error.

## VIBRATION OF $\mathrm{CH}_{2}$

The vibrational energy levels of $\mathrm{CH}_{2}$ may be solved as two equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [2] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERMS OF ${ }^{12} \mathrm{CH}_{2}$

The reentrant oscillation of hybridized orbitals in the transition state is not coupled. Therefore, the equations of the radiation reaction force of dihydrogen and dideuterium carbide are the same as those of the corresponding hydrogen carbide radicals with the substitution of the dihydrogen and dideuterium carbide parameters. Using Eqs. (11.136) and (13.140-13.142), the angular frequency of the reentrant oscillation in the transition state is

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=2.52077 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{13.515}
\end{equation*}
$$

where $b$ is given by Eq. (13.503). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 2.52077 \times 10^{16} \mathrm{rad} / \mathrm{s}=16.59214 \mathrm{eV} \tag{13.516}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each $H_{2}$-type MO, for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.516) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of each of the two bonds for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-31.63537 \mathrm{eV} \sqrt{\frac{2 e(16.59214 \mathrm{eV})}{m_{e} c^{2}}}=-0.25493 \mathrm{eV} \tag{13.517}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of $\mathrm{CH}_{2}$ due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.517) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of each $C-H$ bond. Using $\omega_{e}$ given by Eq. (13.458) for $\bar{E}_{\text {Kvib }}$ of the transition state having two independent bonds, $\bar{E}^{\prime}{ }_{\text {osc }}\left({ }^{12} \mathrm{CH}_{2}\right)$ per bond is:

$$
\begin{align*}
& \bar{E}_{o s c}^{\prime}\left({ }^{12} \mathrm{CH}_{2}\right)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.518}\\
& \bar{E}_{o s c}^{\prime}\left({ }^{12} \mathrm{CH}_{2}\right)=-0.25493 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})=-0.07727 \mathrm{eV} \tag{13.519}
\end{align*}
$$

Given that the vibration and reentrant oscillation is for two $\mathrm{C}-\mathrm{H}$ bonds, $\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{2}\right)$, is:

$$
\begin{align*}
\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{2}\right) & =2\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)  \tag{13.520}\\
& =2\left(-0.25493 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})\right)=-0.15454 \mathrm{eV}
\end{align*}
$$

## TOTAL AND BOND ENERGIES OF ${ }^{12} \mathrm{CH}_{2}$

$E_{T+o s c}\left({ }^{12} \mathrm{CH}_{2}\right)$, the total energy of the ${ }^{12} \mathrm{CH}_{2}$ radical including the Doppler term, is given by the sum of $E_{T}\left(\mathrm{CH}_{2}\right)$ (Eq. (13.497)) and $\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{2}\right)$ given by Eq. (13.520).

$$
\begin{align*}
E_{T+o s c}\left(\mathrm{CH}_{2}\right)= & V_{e}+T+V_{m}+V_{p}+E\left(\mathrm{C}, 2 s p^{3}\right)+\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{2}\right)  \tag{13.521}\\
= & E_{T}\left(\mathrm{CH}_{2}\right)+\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& \left(\left(\frac{-e^{2}}{4 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV}\right)\right.  \tag{13.522}\\
E_{T+o s c}\left({ }^{12} \mathrm{CH}_{2}\right)= & \left\{\begin{array}{l}
\left.-2(31.63536831 \mathrm{eV}) \sqrt{\frac{\frac{3}{\frac{e^{2}}{4} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}}{m_{e}}}-\frac{1}{m_{e} c^{2}} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{array}\right\} \\
= & -49.66493 \mathrm{eV}-2\left(0.25493 \mathrm{eV}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{align*}
$$

From Eqs. (13.518-13.522), the total energy of ${ }^{12} \mathrm{CH}_{2}$ is:

$$
\begin{align*}
E_{T+o s c}\left({ }^{12} \mathrm{CH}_{2}\right) & =-49.66493 \mathrm{eV}+\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =-49.66493 \mathrm{eV}-2\left(0.25493 \mathrm{eV}-\frac{1}{2}(0.35532 \mathrm{eV})\right)=-49.81948 \mathrm{eV} \tag{13.523}
\end{align*}
$$

where $\omega_{e}$ given by Eq. (13.458) was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
${ }^{12} \mathrm{CH}_{2}$ has the same electronic configuration as ${ }^{14} \mathrm{NH}$. The dissociation of the bond of the dihydrogen carbide radical forms a free hydrogen atom with one unpaired electron and a $C 2 s p^{3} \mathrm{HO}$ with three unpaired electrons as shown in Eq. (13.422) wherein the magnetic moments cannot all cancel. Thus, the bond dissociation of ${ }^{12} \mathrm{CH}_{2}$ gives rise to ${ }^{12} \mathrm{CH}$ with the same electronic configuration as $N$ as given by Eq. (10.134). The $N$ configuration is more stable than $H$ as shown in Eqs. (10.14110.143). The lowering of the energy of the reactants decreases the bond energy. The total energy of carbon is reduced by the energy in the field of the two magnetic dipoles given by Eq. (7.46) and Eq. (13.424).

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{2 s p^{3}}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.91771 a_{0}\right)^{3}}=0.14803 \mathrm{eV} \tag{13.524}
\end{equation*}
$$

The $\mathrm{CH}_{2}$ bond dissociation energy, $E_{D}\left({ }^{12} \mathrm{CH}_{2}\right)$, is given by the sum of the total energies of the CH radical and the hydrogen atom minus the sum of $E_{T+o s c}\left({ }^{12} \mathrm{CH}_{2}\right)$ and $E$ (magnetic) :

$$
\begin{equation*}
E_{D}\left({ }^{12} \mathrm{CH}_{2}\right)=E\left({ }^{12} \mathrm{CH}\right)+E(H)-E_{T+o s c}\left({ }^{12} \mathrm{CH}_{2}\right)-E(\text { magnetic }) \tag{13.525}
\end{equation*}
$$

where $E_{T}\left({ }^{12} \mathrm{CH}\right)$ is given by the sum of the energies of the $C 2 s p^{3} \mathrm{HO}, E\left(C, 2 s p^{3}\right)$ given by Eq. (13.428), $E_{D}(H)$ given by Eq. (13.154), and the negative of the bond energy of ${ }^{12} \mathrm{CH}$ given by Eq. (13.489):

$$
\begin{equation*}
E\left({ }^{12} \mathrm{CH}\right)=-13.59844 \mathrm{eV}-14.63489 \mathrm{eV}-3.47 \mathrm{eV}=-31.70333 \mathrm{eV} \tag{13.526}
\end{equation*}
$$

Thus, the ${ }^{12} \mathrm{CH}_{2}$ bond dissociation energy, $E_{D}\left({ }^{12} \mathrm{CH}_{2}\right)$, given by Eqs. (13.154), and (13.523-13.526) is:

$$
\begin{align*}
E_{D}\left({ }^{12} \mathrm{CH}_{2}\right) & =-(31.70333 \mathrm{eV}+13.59844 \mathrm{eV})-\left(E_{T+o s c}\left({ }^{12} \mathrm{CH}_{2}\right)+E(\text { magnetic })\right)  \tag{13.527}\\
& =-45.30177 \mathrm{eV}-(-49.81948 \mathrm{eV}+0.14803 \mathrm{eV})=4.36968 \mathrm{eV}
\end{align*}
$$

The experimental ${ }^{12} \mathrm{CH}_{2}$ bond dissociation energy is [39]:

$$
\begin{equation*}
E_{D}\left({ }^{12} \mathrm{CH}_{2}\right)=4.33064 \mathrm{eV} \tag{13.528}
\end{equation*}
$$

## BOND ANGLE OF ${ }^{12} \mathrm{CH}_{2}$

The $\mathrm{CH}_{2}$ MO comprises a linear combination of two $\mathrm{C}-\mathrm{H}$-bond MOs. Each $\mathrm{C}-\mathrm{H}$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and the $C 2 s p^{3} \mathrm{HO}$ with a relative charge density of 0.75 to 1.25 ; otherwise, the $C 2 s p^{3}$ shell is unchanged. A bond is also possible between the two H atoms of the $C-H$ bonds. Such $H-H$ bonding would decrease the $C-H$ bond strength since electron density would be shifted from the $C-H$ bonds to the $H-H$ bond. Thus, the bond angle between the two $\mathrm{C}-\mathrm{H}$ bonds is determined by the condition that the total energy of the $\mathrm{H}_{2}$-type ellipsoidal MO between the terminal $H$ atoms of the $C-H$ bonds is zero. From Eqs. (11.79) and (13.228), the distance from the origin to each focus of the $H-H$ ellipsoidal MO is

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 2 a}}=\sqrt{\frac{a a_{0}}{2}} \tag{13.529}
\end{equation*}
$$

The internuclear distance from Eq. (13.229) is:

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{\frac{a a_{0}}{2}} \tag{13.530}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal $H-H$ MO $b=c$ is given by Eq. (13.62).
The bond angle of $\mathrm{CH}_{2}$ is derived by using the orbital composition and an energy matching factor as in the case with $\mathrm{NH}_{2}$ and $\mathrm{NH}_{3}$. Since the two $\mathrm{H}_{2}$-type ellipsoidal MOs comprise $75 \%$ of the H electron density of $\mathrm{H}_{2}$ and the energy of each $H_{2}$-type ellipsoidal MO is matched to that of the $C 2 s p^{3} \mathrm{HO}$; the component energies and the total energy $E_{T}$ of the $H-H$ bond are given by Eqs. (13.67-13.73) except that $V_{e}, T$, and $V_{m}$ are corrected for the hybridization-energy-matching factor of 0.91771 given by Eq. (13.430). Substitution of Eq. (13.529) into Eq. (13.233) with the hybridization factor gives:

$$
0=\left[\begin{array}{l}
\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left[(0.91771)^{-1}\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right]\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{\left(2.75 e^{2}\right.}{4 \pi \varepsilon_{0} a^{3}}} \frac{m_{e}}{m_{e} c^{2}}}{}}\right]  \tag{13.531}\\
+\frac{1}{2} \hbar \sqrt{\frac{\frac{0.75 e^{2}}{8 \pi \varepsilon_{0} a^{3}}-\frac{e^{2}}{8 \pi \varepsilon_{0}\left(a+c^{\prime}\right)^{3}}}{0.5 m_{p}}}
\end{array}\right]
$$

From the energy relationship given by Eq. (13.531) and the relationship between the axes given by Eqs. (13.529-13.530) and (13.62-13.63), the dimensions of the $H-H$ MO can be solved.

The most convenient way to solve Eq. (13.531) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a=5.1500 a_{0}=2.7253 \times 10^{-10} \mathrm{~m} \tag{13.532}
\end{equation*}
$$

Substitution of Eq. (13.532) into Eq. (13.529) gives:

$$
\begin{equation*}
c^{\prime}=1.6047 a_{0}=8.4916 \times 10^{-11} \mathrm{~m} \tag{13.533}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.533) by two is:

$$
\begin{equation*}
2 c^{\prime}=3.2094 a_{0}=1.6983 \times 10^{-10} \mathrm{~m} \tag{13.534}
\end{equation*}
$$

Substitution of Eqs. (13.532-13.533) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=4.8936 a_{0}=2.5896 \times 10^{-10} \mathrm{~m} \tag{13.535}
\end{equation*}
$$

Substitution of Eqs. (13.532-13.533) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.3116 \tag{13.536}
\end{equation*}
$$

Using, $2 c^{\prime}{ }_{H-H}$ (Eq. (13.534)), the distance between the two $H$ atoms when the total energy of the corresponding MO is zero (Eq. (13.531)), and $2{c^{\prime}}_{C-H}$ (Eq. (13.501)), the internuclear distance of each $C-H$ bond, the corresponding bond angle can be determined from the law of cosines. Using, Eq. (13.242), the bond angle $\theta$ between the $C-H$ bonds is:

$$
\begin{equation*}
\theta=\cos ^{-1}\left(\frac{2(2.09132)^{2}-(3.2094)^{2}}{2(2.09132)^{2}}\right)=\cos ^{-1}(-0.1775)=100.22^{\circ} \tag{13.537}
\end{equation*}
$$

The experimental angle between the $C-H$ bonds is [38]:

$$
\begin{equation*}
\theta=102.4^{\circ} \tag{13.538}
\end{equation*}
$$

The results of the determination of bond parameters of $\mathrm{CH}_{2}$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## METHYL RADICAL ( $\mathrm{CH}_{3}$ )

The methyl radical $\mathrm{CH}_{3}$ is formed by the reaction of a hydrogen atom with a dihydrogen carbide radical:

$$
\begin{equation*}
\mathrm{CH}_{2}+\mathrm{H} \rightarrow \mathrm{CH}_{3} \tag{13.539}
\end{equation*}
$$

$\mathrm{CH}_{3}$ can be solved using the same principles as those used to solve $\mathrm{NH}_{3}$ with the exception that the carbon $2 s$ and $2 p$ shells hybridize to form a single $2 s p^{3}$ shell as an energy minimum. Three diatomic molecular orbitals (MOs) developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section serve as basis functions in a linear combination with three carbon $2 s p^{3}$ hybridized orbitals (HOs) to form the MO of $\mathrm{CH}_{3}$. The solution is very similar to that of $\mathrm{CH}_{2}$ except that there are three CH bonds in $\mathrm{CH}_{3}$.

## FORCE BALANCE OF $\mathrm{CH}_{3}$

$\mathrm{CH}_{3}$ comprises three chemical bonds between carbon and hydrogen atoms. Each $\mathrm{C}-\mathrm{H}$ bond comprises two spin-paired electrons with one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom. Each $H$-atom electron forms an $H_{2}$-type ellipsoidal MO with an unpaired $C$-atom electron. However, such a bond is not possible with the outer two $C$ electrons in their ground state since the resulting $H_{2}$-type ellipsoidal MO would have a shorter internuclear distance than the radius of the carbon $2 p$ shell which is not energetically stable, and only two electrons are unpaired. Thus, when bonding the carbon $2 s$ and $2 p$ shells hybridize to form a single $2 s p^{3}$ shell as an energy minimum. The electron configuration and the energy, $E\left(C, 2 s p^{3}\right)$, of the $C 2 s p^{3}$ shell is given by Eqs. (13.422), and (13.428), respectively.

For each $C-H$ bond, a $C 2 s p^{3}$ electron combines with the $H 1 s$ electron to form a molecular orbital. The proton of the $H$ atom and the nucleus of the $C$ atom are along each internuclear axis and serve as the foci. As in the case of $H_{2}$, each of the three $C-H$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $C 2 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C 2 s p^{3}$ shell since it is energetically unfavorable. Thus, each MO surface comprises a prolate spheroid at the $H$ proton that is continuous with the $C 2 s p^{3}$ shell at the $C$ atom whose nucleus serves as the other focus. The radius and the energy of the $C 2 s p^{3}$ shell are unchanged with bond formation. The central paramagnetic force due to spin of each $\mathrm{C}-\mathrm{H}$ bond is provided by the spin-pairing force of the $\mathrm{CH}_{3} \mathrm{MO}$ that has the symmetry of an $s$ orbital that superimposes with the $C 2 s p^{3}$ orbitals such that the corresponding angular momenta are unchanged.

The energies in the $\mathrm{CH}_{3}$ MO involve only each $\mathrm{C} 2 s p^{3}$ and each $H 1 s$ electron with the formation of each $\mathrm{C}-\mathrm{H}$ bond. The sum of the energies of the $\mathrm{H}_{2}$-type ellipsoidal MOs is matched to that of the $\mathrm{C} 2 \mathrm{sp}{ }^{3}$ shell. As in the cases with of OH , $\mathrm{H}_{2} \mathrm{O}, \mathrm{NH}, \mathrm{NH}_{2}, \mathrm{NH}_{3}, \mathrm{CH}$, and $\mathrm{CH}_{2}$ the linear combination of each $\mathrm{H}_{2}$-type ellipsoidal MO with the $\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO}$ must involve a $25 \%$ contribution from the $H_{2}$-type ellipsoidal MO to the $C 2 s p^{3} \mathrm{HO}$ in order to match potential, kinetic, and orbital energy relationships. Thus, the $\mathrm{CH}_{3}$ MO must comprise three $\mathrm{C}-\mathrm{H}$ bonds with each comprising $75 \%$ of a $H_{2}$-type ellipsoidal MO and a $C 2 s p^{3} \mathrm{HO}:$

$$
\begin{equation*}
3\left[1 \mathrm{C}_{2} s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO}\right] \rightarrow \mathrm{CH}_{3} \mathrm{MO} \tag{13.540}
\end{equation*}
$$

The force balance of the $\mathrm{CH}_{3} \mathrm{MO}$ is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.540) and the energy matching condition between the hydrogen and $C 2 s p^{3} \mathrm{HO}$ components of the MO.

The force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ of each $H_{2}$-type-ellipsoidal-MO component of the $\mathrm{CH}_{3}$ MO in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus $c^{\prime}$ is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $C-H$-bond MO. Since each of the three prolate spheroidal $C-H$-bond MOs comprises a $H_{2}$-type-ellipsoidal MO that transitions to the $C 2 s p^{3} \mathrm{HO}$, the energy $E\left(C, 2 s p^{3}\right)$ in Eq. (13.428) adds to that of the three corresponding $H_{2}$-type ellipsoidal MOs to give the total energy of the $\mathrm{CH}_{3} \mathrm{MO}$. From the energy equation and the relationship between the axes, the dimensions of the $\mathrm{CH}_{3} \mathrm{MO}$ are solved.

The energy components of $V_{e}, V_{p}, T$, and $V_{m}$ are three times those of $C H$ corresponding to the three $C-H$ bonds. Since each prolate spheroidal $H_{2}$-type MO transitions to the $C 2 s p^{3} \mathrm{HO}$ and the energy of the $C 2 s p^{3}$ shell must remain constant and equal to the $E\left(C, 2 s p^{3}\right)$ given by Eq. (13.428), the total energy $E_{T}\left(\mathrm{CH}_{3}\right)$ of the $\mathrm{CH}_{3} \mathrm{MO}$ is given by the sum of the
energies of the orbitals corresponding to the composition of the linear combination of the $\mathrm{C} 2 s p^{3} \mathrm{HO}$ and the three $\mathrm{H}_{2}$-type ellipsoidal MOs that forms the $\mathrm{CH}_{3} \mathrm{MO}$ as given by Eq. (13.540). Using Eq. (13.431), $E_{T}\left(\mathrm{CH}_{3}\right)$ is given by:

$$
\begin{align*}
E_{T}\left(C H_{3}\right) & =E_{T}+E\left(C, 2 s p^{3}\right) \\
& =-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV} \tag{13.541}
\end{align*}
$$

The three hydrogen atoms and the hybridized carbon atom can achieve an energy minimum as a linear combination of three $\mathrm{H}_{2}$ type ellipsoidal MOs each having the proton and the carbon nucleus as the foci. Hybridization gives rise to the $C 2 s p^{3}$ HO-shell Coulombic energy $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ given by Eq. (13.425). To meet the equipotential condition of the union of the $H_{2}$-type-ellipsoidal-MO and the $C 2 s p^{3}$ HO, the electron energies in Eqs. (13.431), (13.495), and (13.541) were normalized by the ratio of 14.82575 eV , the magnitude of $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ given by Eq. (13.425), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.224). The factor given by Eq. (13.430) normalized the energies to match that of the Coulombic energy alone to meet the energy matching condition of each $C-H$-bond MO under the influence of the proton and the $C$ nucleus. Each $C-H$-bond MO comprises the same $C 2 s p^{3}$ shell having its energy normalized to that of the Coulombic energy between the electron and a charge of $+e$ at the carbon focus of the $\mathrm{CH}_{3} \mathrm{MO}$. Thus, the energy of the $\mathrm{CH}_{3} \mathrm{MO}$ is also given by the sum of that of the three $\mathrm{H}_{2}$-type ellipsoidal MOs given by Eq. (11.212) minus two times the Coulombic energy, $E_{\text {Coulomb }}(H)=-13.605804 \mathrm{eV}$, of the two redundant $+e$ 's of the linear combination:

$$
\begin{align*}
E_{T}\left(3 H_{2}-2 H\right) & =-\frac{3 e^{2}}{8 \pi \varepsilon_{0} a_{0}}\left[\left(2 \sqrt{2}-\sqrt{2}+\frac{\sqrt{2}}{2}\right) \ln \frac{\sqrt{2}+1}{\sqrt{2}-1}-\sqrt{2}\right]-2 E_{\text {Coulomb }}(H)  \tag{13.542}\\
& =3(-31.63536831 \mathrm{eV})-2(-13.605804 \mathrm{eV})=-67.69450 \mathrm{eV}
\end{align*}
$$

$E_{T}\left(\mathrm{CH}_{3}\right)$ given by Eq. (13.541) is set equal to three times the energy of the $H_{2}$-type ellipsoidal MO minus two times the Coulombic energy of $H$ given by Eq. (13.542).

$$
\begin{align*}
E_{T}\left(C H_{3}\right) & =-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV}  \tag{13.543}\\
& =-67.69450 \mathrm{eV}
\end{align*}
$$

From the energy relationship given by Eq. (13.543) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the $\mathrm{CH}_{3} \mathrm{MO}$ can be solved.

Substitution of Eq. (13.60) into Eq. (13.543) gives:

$$
\begin{equation*}
\frac{3 e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right]=e 53.05961 \tag{13.544}
\end{equation*}
$$

The most convenient way to solve Eq. (13.544) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is

$$
\begin{equation*}
a=1.62893 a_{0}=8.61990 \times 10^{-11} \mathrm{~m} \tag{13.545}
\end{equation*}
$$

Substitution of Eq. (13.545) into Eq. (13.60) gives:

$$
\begin{equation*}
c^{\prime}=1.04209 a_{0}=5.51450 \times 10^{-11} \mathrm{~m} \tag{13.546}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.546) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.08418 a_{0}=1.10290 \times 10^{-10} \mathrm{~m} \tag{13.547}
\end{equation*}
$$

The experimental bond distance is [38]:

$$
\begin{equation*}
2 c^{\prime}=1.079 \times 10^{-10} \mathrm{~m} \tag{13.548}
\end{equation*}
$$

Substitution of Eqs. (13.545-13.546) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=1.25198 a_{0}=6.62518 \times 10^{-11} \mathrm{~m} \tag{13.549}
\end{equation*}
$$

Substitution of Eqs. (13.545-13.546) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.63974 \tag{13.550}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $C$ atom comprise the foci of each $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of each $H_{2}$-type ellipsoidal MO and the $C 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95), (13.26113.270), and (13.434-13.442). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{2 s p^{3}}=0.91771 a_{0}$ is the radius of the $C 2 s p^{3}$ shell. Substitution of Eqs. (13.545-13.546) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=85.65^{\circ} \tag{13.551}
\end{equation*}
$$

Then, the angle $\theta_{C 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C 2 s p^{3} H O}=180^{\circ}-85.65^{\circ}=94.35^{\circ} \tag{13.552}
\end{equation*}
$$

as shown in Figure 13.9. The parametric angle $\theta_{\mathrm{H}_{2} \mathrm{MO}}$ given by Eqs. (13.442-13.443), (13.549), and (13.552) is:

$$
\begin{equation*}
\theta_{H_{2} M O}=46.96^{\circ} \tag{13.553}
\end{equation*}
$$

Then, the distance $d_{\mathrm{H}_{2} M O}$ along the internuclear axis from the origin of $\mathrm{H}_{2}$-type ellipsoidal MO to the point of intersection of the orbitals given by Eqs. (13.445), (13.545), and (13.553) is:

$$
\begin{align*}
d_{H_{2} M O} & =1.11172 a_{0}  \tag{13.554}\\
& =5.88295 \times 10^{-11} \mathrm{~m}
\end{align*}
$$

The distance $d_{C 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals given by Eqs. (13.447), (13.546), and (13.554) is:

$$
\begin{equation*}
d_{C 2 s p^{3} H O}=0.06963 a_{0}=3.68457 \times 10^{-12} \mathrm{~m} \tag{13.555}
\end{equation*}
$$

As shown in Eq. (13.540), the uniform charge-density in the $C 2 s p^{3} \mathrm{HO}$ is increased by a factor of 0.25 and the $H$-atom density is decreased by a factor of 0.25 for by each $\mathrm{C}-\mathrm{H}$ bond. Using the orbital composition of $\mathrm{CH}_{3}$ (Eq. (13.540)), the radii of $C 1 s=0.17113 a_{0}$ (Eq. (10.51)) and $C 2 s p^{3}=0.91771 a_{0}$ (Eq. (13.424)) shells, and the parameters of the $\mathrm{CH}_{3}$ MO given by Eqs. (13.3-13.4), (13.545-13.547), and (13.549-13.555), the charge-density of the $\mathrm{CH}_{3} \mathrm{MO}$ comprising the linear combination of three $C-H$-bond MOs is shown in Figure 13.12. Each $C-H$-bond MO comprises a $H_{2}$-type ellipsoidal MO and a $C 2 s p^{3}$ HO having the dimensional diagram shown in Figure 13.9.

Figure 13.12. $\mathrm{CH}_{3} \mathrm{MO}$ comprising the linear combination of three $\mathrm{C}-\mathrm{H}$-bond MOs. Each $\mathrm{C}-\mathrm{H}$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and a $C 2 s p^{3} \mathrm{HO}$ with a relative charge-density of 0.75 to 1.25 ; otherwise, the $C 2 s p^{3} \mathrm{HO}$ shell is unchanged. (A) Color scale, translucent view of the charge-density of the $\mathrm{CH}_{3} \mathrm{MO}$ from the top. For each $C-H$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C 2 s p^{3} \mathrm{HO}$, the $C 2 s p^{3} \mathrm{HO}$ shell, $C 1 s$ shell, and the nuclei (red, not to scale) are shown. (B) Cut-away view showing the inner most $C 1 s$ shell, and moving radially, the $C 2 s p^{3}$ shell, and the $H_{2}$-type ellipsoidal MO that transitions to the $C 2 s p^{3} \mathrm{HO}$ for each $C-H$ bond. Bisector current not shown. (C)-(E) Color scale, bottom, top, and side-on translucent views of the charge-density of the $\mathrm{CH}_{3} \mathrm{MO}$, respectively.

## ENERGIES OF $\mathrm{CH}_{3}$

The energies of $\mathrm{CH}_{3}$ are three times those of CH and are given by the substitution of the semiprincipal axes (Eqs. (13.54513.546 ) and (13.549)) into the energy equations Eq. (13.541) and (Eqs. (13.449-13.452)) that are multiplied by three:

$$
\begin{align*}
& V_{e}=3(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-108.94944 \mathrm{eV}  \tag{13.556}\\
& V_{p}=\frac{3 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=39.16883 \mathrm{eV}  \tag{13.557}\\
& T=3(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=33.44213 \mathrm{eV}  \tag{13.558}\\
& V_{m}=3(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-16.72107 \mathrm{eV}  \tag{13.559}\\
& E_{T}\left(\mathrm{CH}_{3}\right)=-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV}=-67.69444 \mathrm{eV}
\end{align*}
$$

where $E_{T}\left(\mathrm{CH}_{3}\right)$ is given by Eq. (13.541) which is reiteratively matched to Eq. (13.542) within five-significant-figure-round-offerror.

## VIBRATION OF $\mathrm{CH}_{3}$

The vibrational energy levels of $\mathrm{CH}_{3}$ may be solved as three equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [2] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERMS OF ${ }^{12} \mathrm{CH}_{3}$

The reentrant oscillation of hybridized orbitals in the transition state is not coupled. Therefore, the equations of the radiation reaction force of methyl radical are the same as those of the corresponding hydrogen carbide radicals with the substitution of the methyl radical parameters. Using Eqs. (11.136) and (13.140-13.142), the angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=2.55577 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{13.561}
\end{equation*}
$$

where $b$ is given by Eq. (13.549). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 2.55577 \times 10^{16} \mathrm{rad} / \mathrm{s}=16.82249 \mathrm{eV} \tag{13.562}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each $H_{2}$-type MO, for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.562) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$
\begin{align*}
\bar{E}_{D} & \cong E_{h v} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}  \tag{13.563}\\
& =-31.63537 \mathrm{eV} \sqrt{\frac{2 e(16.82249 \mathrm{eV})}{m_{e} c^{2}}}=-0.25670 \mathrm{eV}
\end{align*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of $\mathrm{CH}_{3}$ due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.563) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of each $C-H$ bond. Using $\omega_{e}$ given by Eq. (13.458) for $\bar{E}_{\text {Kvib }}$ of the transition state having three independent bonds, $\bar{E}_{\text {osc }}^{\prime}\left({ }^{12} \mathrm{CH}_{3}\right)$ per bond is

$$
\begin{equation*}
\bar{E}_{o s c}^{\prime}\left({ }^{12} \mathrm{CH}_{3}\right)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}} \tag{13.564}
\end{equation*}
$$

$$
\begin{equation*}
\bar{E}_{o s c}^{\prime}\left({ }^{12} \mathrm{CH}_{3}\right)=-0.25670 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})=-0.07904 \mathrm{eV} \tag{13.565}
\end{equation*}
$$

Given that the vibration and reentrant oscillation is for three $\mathrm{C}-\mathrm{H}$ bonds, $\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{3}\right)$, is:

$$
\begin{align*}
\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{3}\right) & =3\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)  \tag{13.566}\\
& =3\left(-0.25670 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})\right)=-0.23711 \mathrm{eV}
\end{align*}
$$

## TOTAL AND BOND ENERGIES OF ${ }^{12} \mathrm{CH}_{3}$

$E_{T+o s c}\left({ }^{12} \mathrm{CH}_{3}\right)$, the total energy of the ${ }^{12} \mathrm{CH}_{3}$ radical including the Doppler term, is given by the sum of $E_{T}\left(\mathrm{CH}_{3}\right)$ (Eq. (13.543)) and $\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{3}\right)$ given by Eq. (13.566).

$$
\begin{align*}
E_{T+o s c}\left(\mathrm{CH}_{3}\right)= & V_{e}+T+V_{m}+V_{p}+E\left(\mathrm{C}, 2 s p^{3}\right)+\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{3}\right)=E_{T}\left(\mathrm{CH}_{3}\right)+\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{3}\right)  \tag{13.567}\\
E_{T+o s c}\left({ }^{12} \mathrm{CH}_{3}\right) & =\left\{\begin{array}{l}
\left(\frac{-3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV}\right) \\
-3(31.63536831 \mathrm{eV}) \sqrt{\frac{\frac{3}{\frac{3}{4} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}}{m_{e}}}-\frac{1}{m_{e} c^{2}} \hbar \sqrt{\frac{k}{\mu}}
\end{array}\right)  \tag{13.568}\\
& =-67.69450 \mathrm{eV}-3\left(0.25670 \mathrm{eV}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{align*}
$$

From Eqs. (13.564-13.568), the total energy of ${ }^{12} \mathrm{CH}_{3}$ is:

$$
\begin{align*}
E_{T+o s c}\left({ }^{12} \mathrm{CH}_{3}\right) & =-67.69450 \mathrm{eV}+\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{3}\right) \\
& =-67.69450 \mathrm{eV}-3\left(0.25670 \mathrm{eV}-\frac{1}{2}(0.35532 \mathrm{eV})\right)  \tag{13.569}\\
& =-67.93160 \mathrm{eV}
\end{align*}
$$

where $\omega_{e}$ given by Eq. (13.458) was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The $\mathrm{CH}_{3}$ bond dissociation energy, $\mathrm{E}_{\mathrm{D}}\left({ }^{12} \mathrm{CH}_{3}\right)$, is given by the sum of the total energies of the $\mathrm{CH}_{2}$ radical and the hydrogen atom minus $E_{T+o s c}\left({ }^{12} \mathrm{CH}_{3}\right)$ :

$$
\begin{equation*}
E_{D}\left({ }^{12} \mathrm{CH}_{3}\right)=E\left({ }^{12} \mathrm{CH}_{2}\right)+E(H)-E_{T+o s c}\left({ }^{12} \mathrm{CH}_{3}\right) \tag{13.570}
\end{equation*}
$$

where $E_{T}\left({ }^{12} \mathrm{CH}_{2}\right)$ is given by the sum of the energies of the $C 2 s p^{3} \mathrm{HO}, E\left(C, 2 s p^{3}\right)$ given by Eq. (13.428), $2 E_{D}(H)$ given by Eq. (13.154), and the negative of the bond energies of ${ }^{12} \mathrm{CH}$ given by Eq. (13.489) and ${ }^{12} \mathrm{CH}_{2}$ given by Eq. (13.528):

$$
\begin{align*}
E\left({ }^{12} \mathrm{CH}_{2}\right) & =2(-13.59844 \mathrm{eV})-14.63489 \mathrm{eV}-3.47 \mathrm{eV}-4.33064 \mathrm{eV}  \tag{13.571}\\
& =-49.63241 \mathrm{eV}
\end{align*}
$$

Thus, the ${ }^{12} \mathrm{CH}_{3}$ bond dissociation energy, $E_{D}\left({ }^{12} \mathrm{CH}_{3}\right)$, given by Eqs. (13.154), and (13.569-13.571) is:

$$
\begin{align*}
E_{D}\left({ }^{12} \mathrm{CH}_{3}\right) & =+(-49.63241 \mathrm{eV}-13.59844 \mathrm{eV})-E_{T+o s c}\left({ }^{12} \mathrm{CH}_{3}\right) \\
& =-63.23085 \mathrm{eV}-(-67.93160 \mathrm{eV})  \tag{13.572}\\
& =4.70075 \mathrm{eV}
\end{align*}
$$

The experimental ${ }^{12} \mathrm{CH}_{3}$ bond dissociation energy is [40]

$$
\begin{equation*}
E_{D}\left({ }^{12} \mathrm{CH}_{3}\right)=4.72444 \mathrm{eV} \tag{13.573}
\end{equation*}
$$

## BOND ANGLE OF ${ }^{12} \mathrm{CH}_{3}$

Consider the case that all of the MOs can participate in a superposition involving bonding of the terminal atoms. Then, solving for $2 c_{H-H}^{\prime}=3.61109 a_{0}$, the distance between any adjacent two $H$ atoms when the total energy of the corresponding MO is zero given by Eq. (13.531) with the replacement of the hybridization factor and energy terms with $(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right)$ of Eq. (13.568), and $2 c^{\prime}{ }_{C-H}$, the internuclear distance of each $C-H$ bond (Eq. (13.547)), the corresponding bond angle can be determined from the law of cosines. Using Eq. (13.537), the bond angle $\theta$ between the $C-H$ bonds is:

$$
\begin{equation*}
\theta=\cos ^{-1}\left(\frac{2(2.08418)^{2}-(3.61109)^{2}}{2(2.08418)^{2}}\right)=\cos ^{-1}(-0.50099)=120^{\circ} \tag{13.574}
\end{equation*}
$$

which is in agreement with $D_{3 h}$ symmetry [38].
The $\mathrm{CH}_{3}$ radical has a pyramidal structure with the carbon atom along the z -axis at the apex and the hydrogen atoms at the base in the xy-plane. The distance $d_{\text {origin-H }}$ from the origin to the nucleus of a hydrogen atom given by Eqs. (13.534) and (13.412) is:

$$
\begin{equation*}
d_{\text {origin-H }}=2.0848 a_{0} \tag{13.575}
\end{equation*}
$$

The height along the z-axis of the pyramid from the origin to the $C$ nucleus is $d_{\text {height }}$ given by Eqs. (13.414), (13.547), and (13.575) is:

$$
\begin{equation*}
d_{\text {height }}=0 a_{0} \tag{13.576}
\end{equation*}
$$

The angle $\theta_{v}$ of each $C-H$ bond from the z-axis given by Eqs. (13.416), (13.575), and (13.576) is:
$\theta_{v}=90^{\circ}$
The $\mathrm{CH}_{3} \mathrm{MO}$ shown in Figure 13.12 was rendered using these parameters.
The results of the determination of bond parameters of $\mathrm{CH}_{3}$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## METHANE MOLECULE ( $\mathrm{CH}_{4}$ )

The methane molecule $\mathrm{CH}_{4}$ is formed by the reaction of a hydrogen atom with a methyl radical:

$$
\begin{equation*}
\mathrm{CH}_{3}+\mathrm{H} \rightarrow \mathrm{CH}_{4} \tag{13.578}
\end{equation*}
$$

$\mathrm{CH}_{4}$ can be solved using the same principles as those used to solve and $\mathrm{CH}_{3}$ wherein the carbon $2 s$ and $2 p$ shells hybridize to form a single $2 s p^{3}$ shell as an energy minimum. Four diatomic molecular orbitals (MOs) developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section serve as basis functions in a linear combination with four carbon $2 s p^{3}$ hybridized orbitals (HOs) to form the MO of $\mathrm{CH}_{4}$. The solution is very similar to that of $\mathrm{CH}_{3}$ except that there are four CH bonds in $\mathrm{CH}_{4}$. Methane is the simplest hydrocarbon that can be solved using the results for $\mathrm{CH}_{3}$. From the solution of $\mathrm{CH}_{2}$ as well as $\mathrm{CH}_{3}$, more complex hydrocarbons can be solved using these radicals as basis elements with bonding between the $C 2 s p^{3}$ hybridized carbons.

## FORCE BALANCE OF $\mathrm{CH}_{4}$

$\mathrm{CH}_{4}$ comprises four chemical bonds between carbon and hydrogen atoms. Each $\mathrm{C}-\mathrm{H}$ bond comprises two spin-paired electrons with one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom. Each $H$-atom electron forms a $\mathrm{H}_{2}$-type ellipsoidal MO with an unpaired C -atom electrons. However, such a bond is not possible with the outer two $C$ electrons in their ground state since the resulting $H_{2}$-type ellipsoidal MO would have a shorter internuclear distance than the radius of the carbon $2 p$ shell which is not energetically stable, and only two electrons are unpaired. Thus, when bonding the carbon $2 s$ and $2 p$ shells hybridize to form a single $2 s p^{3}$ shell as an energy minimum. The electron configuration and the energy, $E\left(C, 2 s p^{3}\right)$, of the $C 2 s p^{3}$ shell is given by Eqs. (13.422), and (13.428), respectively.

For each $C-H$ bond, a $C 2 s p^{3}$ electron combines with the $H 1 s$ electron to form a molecular orbital. The proton of the $H$ atom and the nucleus of the $C$ atom are along each internuclear axis and serve as the foci. As in the case of $H_{2}$, each of the four $C-H$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into the $C 2 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C 2 s p^{3}$ shell since it is energetically unfavorable. Thus, each MO surface comprises a prolate spheroid at the $H$ proton that can be solved as being continuous with the $C 2 s p^{3}$ shell at the $C$ atom whose nucleus
serves as the other focus. The radius and the energy of the $C 2 s p^{3}$ shell are unchanged with bond formation. The central paramagnetic force due to spin of each $\mathrm{C}-\mathrm{H}$ bond is provided by the spin-pairing force of the $\mathrm{CH}_{4} \mathrm{MO}$ that has the symmetry of an $s$ orbital that superimposes with the $C 2 s p^{3}$ orbitals such that the corresponding angular momenta are unchanged.

The energies in the $\mathrm{CH}_{4}$ MO involve only each $C 2 s p^{3}$ and each $H 1 s$ electron with the formation of each $C-H$ bond. The sum of the energies of the $\mathrm{H}_{2}$-type ellipsoidal MOs is matched to that of the $\mathrm{C} 2 \mathrm{sp}{ }^{3}$ shell. As in the cases of $\mathrm{OH}, \mathrm{H}_{2} \mathrm{O}$, $\mathrm{NH}, \mathrm{NH}_{2}, \mathrm{NH}_{3}, \mathrm{CH}, \mathrm{CH}_{2}$, and $\mathrm{CH}_{3}$ the $\mathrm{CH}_{4}$ MO must comprise four $\mathrm{C}-\mathrm{H}$ bonds with each having $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO and a $C 2 s p^{3} \mathrm{HO}$ in a linear combination in order to match potential, kinetic, and orbital energy relationships:

$$
\begin{equation*}
4\left[1 \mathrm{C} 2 s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO}\right] \rightarrow \mathrm{CH}_{4} \mathrm{MO} \tag{13.579}
\end{equation*}
$$

The force balance of the $\mathrm{CH}_{4} \mathrm{MO}$ is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.579) and the energy matching condition between the hydrogen and $C 2 s p^{3} \mathrm{HO}$ components of the MO.

The force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ of the each $H_{2}$-type-ellipsoidal-MO component of the $\mathrm{CH}_{4} \mathrm{MO}$ in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus $c^{\prime}$ is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $\mathrm{C}-\mathrm{H}-$ bond MO. Since each of the four prolate spheroidal $C-H$-bond MOs comprises a $H_{2}$-type-ellipsoidal MO that transitions to the $C 2 s p^{3} \mathrm{HO}$, the energy $E\left(C, 2 s p^{3}\right)$ in Eq. (13.428) adds to that of the four corresponding $H_{2}$-type ellipsoidal MOs to give the total energy of the $\mathrm{CH}_{4} \mathrm{MO}$. From the energy equation and the relationship between the axes, the dimensions of the $\mathrm{CH}_{4}$ MO are solved.

The energy components of $V_{e}, V_{p}, T$, and $V_{m}$ are four times those of $C H$ corresponding to the four $C-H$ bonds. Since each prolate spheroidal $H_{2}$-type MO transitions to the $C 2 s p^{3} \mathrm{HO}$ and the energy of the $C 2 s p^{3}$ shell must remain constant and equal to the $E\left(C, 2 s p^{3}\right)$ given by Eq. (13.428), the total energy $E_{T}\left(\mathrm{CH}_{4}\right)$ of the $\mathrm{CH}_{4} \mathrm{MO}$ is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $\mathrm{C} 2 s p^{3} \mathrm{HO}$ and the four $\mathrm{H}_{2}$-type ellipsoidal MOs that forms the $\mathrm{CH}_{4} \mathrm{MO}$ as given by Eq. (13.579). Using Eq. (13.431), $E_{T}\left(\mathrm{CH}_{4}\right)$ is given by:

$$
\begin{equation*}
E_{T}\left(C H_{4}\right)=E_{T}+E\left(C, 2 s p^{3}\right)=-\frac{4 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV} \tag{13.580}
\end{equation*}
$$

The four hydrogen atoms and the hybridized carbon atom can achieve an energy minimum as a linear combination of four $\mathrm{H}_{2}$ type ellipsoidal MOs each having the proton and the carbon nucleus as the foci. Hybridization gives rise to the $C 2 s p^{3}$ HO-shell Coulombic energy $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ given by Eq. (13.435). To meet the equipotential condition of the union of the $H_{2}$-type-ellipsoidal-MO and the $C 2 s p^{3} \mathrm{HO}$, the electron energies in Eqs. (13.431), (13.495), (13.541), and (13.580) were normalized by the ratio of 14.82575 eV , the magnitude of $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ given by Eq. (13.425), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). The factor given by Eq. (13.430) normalized the energies to match that of the Coulombic energy alone to meet the energy matching condition of each $C-H$-bond MO under the influence of the proton and the $C$ nucleus. Each $C-H$-bond MO comprises the same $C 2 s p^{3}$ shell having its energy normalized to that of the Coulombic energy between the electron and a charge of $+e$ at the carbon focus of the $\mathrm{CH}_{4} \mathrm{MO}$. Thus, the energy of the $\mathrm{CH}_{4} \mathrm{MO}$ is also given by the sum of that of the four $\mathrm{H}_{2}$-type ellipsoidal MOs given by Eq. (11.212) minus three times the Coulombic energy, $E_{\text {Coulomb }}(H)=-13.605804 \mathrm{eV}$, of the three redundant $+e$ 's of the linear combination:

$$
\begin{align*}
E_{T}\left(4 H_{2}-3 H\right) & =-\frac{4 e^{2}}{8 \pi \varepsilon_{0} a_{0}}\left[\left(2 \sqrt{2}-\sqrt{2}+\frac{\sqrt{2}}{2}\right) \ln \frac{\sqrt{2}+1}{\sqrt{2}-1}-\sqrt{2}\right]-3 E_{\text {Coulomb }}(H) \\
& =4(-31.63536831 \mathrm{eV})-3(-13.605804 \mathrm{eV})  \tag{13.581}\\
& =-85.72406 \mathrm{eV}
\end{align*}
$$

$E_{T}\left(\mathrm{CH}_{4}\right)$ given by Eq. (13.580) is set equal to four times the energy of the $H_{2}$-type ellipsoidal MO minus three times the Coulombic energy of $H$ given by Eq. (13.581):

$$
\begin{equation*}
E_{T}\left(C H_{4}\right)=-\frac{4 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV}=-85.72406 \mathrm{eV} \tag{13.582}
\end{equation*}
$$

From the energy relationship given by Eq. (13.582) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the $\mathrm{CH}_{4} \mathrm{MO}$ can be solved.

> Substitution of Eq. (13.60) into Eq. (13.543) gives:

$$
\begin{equation*}
\frac{4 e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right]=e 71.08917 \tag{13.583}
\end{equation*}
$$

The most convenient way to solve Eq. (13.583) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is

$$
\begin{equation*}
a=1.62340 a_{0}=8.59066 \times 10^{-11} \mathrm{~m} \tag{13.584}
\end{equation*}
$$

Substitution of Eq. (13.584) into Eq. (13.60) gives:

$$
\begin{equation*}
c^{\prime}=1.04032 a_{0}=5.50514 \times 10^{-11} \mathrm{~m} \tag{13.585}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.585) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.08064 a_{0}=1.10103 \times 10^{-10} \mathrm{~m} \tag{13.586}
\end{equation*}
$$

The experimental bond distance is [41]:

$$
\begin{equation*}
2 c^{\prime}=1.087 \times 10^{-10} \mathrm{~m} \tag{13.587}
\end{equation*}
$$

Substitution of Eqs. (13.584-13.585) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=1.24626 a_{0}=6.59492 \times 10^{-11} \mathrm{~m} \tag{13.588}
\end{equation*}
$$

Substitution of Eqs. (13.584-13.585) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.64083 \tag{13.589}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $C$ atom comprise the foci of each $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of each $H_{2}$-type ellipsoidal MO and the $C 2 s p^{3} \mathrm{HO}$ in the absence of the other three are given by Eqs. (13.84-13.95), (13.261-13.270), (13.434-13.442), and (13.551-13.555). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{2 s p^{3}}=0.91771 a_{0}$ is the radius of the $C 2 s p^{3}$ shell. Substitution of Eqs. (13.584-13.585) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=86.20^{\circ} \tag{13.590}
\end{equation*}
$$

Then, the angle $\theta_{C 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C 2 s p^{3} H O}=180^{\circ}-86.20^{\circ}=93.80^{\circ} \tag{13.591}
\end{equation*}
$$

as shown in Figure 13.9. The parametric angle $\theta_{\mathrm{H}_{2} \mathrm{MO}}$ given by Eqs. (13.442-13.443), (13.588), and (13.591) is:

$$
\begin{equation*}
\theta_{\mathrm{H}_{2} M O}=47.29^{\circ} \tag{13.592}
\end{equation*}
$$

Then, the distance $d_{\mathrm{H}_{2} \mathrm{MO}}$ along the internuclear axis from the origin of $\mathrm{H}_{2}$-type ellipsoidal MO to the point of intersection of the orbitals given by Eqs. (13.445), (13.584), and (13.592) is:

$$
\begin{equation*}
d_{H_{2} M O}=1.10121 a_{0}=5.82734 \times 10^{-11} \mathrm{~m} \tag{13.593}
\end{equation*}
$$

The distance $d_{C 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals given by Eqs. (13.447), (13.585), and (13.593) is:

$$
\begin{equation*}
d_{C 2 s p^{3} H O}=0.06089 a_{0}=3.22208 \times 10^{-12} \mathrm{~m} \tag{13.594}
\end{equation*}
$$

The $\mathrm{H}_{2}$-type ellipsoidal MOs do not actually directly contact the $\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO}$. As discussed in the Force Balance of $\mathrm{H}_{2} \mathrm{O}$ section, with the addition of the fourth $\mathrm{C}-\mathrm{H}$ bond, the $\mathrm{H}_{2}$-type ellipsoidal MOs may linearly combine to form a continuous two-dimensional surface of equipotential equivalent to that of the MOs if they did contact the $C 2 s p^{3} \mathrm{HO}$. However, Eqs. (13.579-13.580) must hold based on conservation of momentum and the potential, kinetic, and total energy relationships. In order that there is current continuity given the constraints of Eqs. (13.579-13.580), the existence of a self-contained, continuouscurrent, linear-combination of the $H_{2}$-type ellipsoidal MOs requires that electrons are divisible between the combination $\mathrm{H}_{2}$ type MO and the $C 2 s p^{3} \mathrm{HO}$. This is not possible.

Thus, at the points of intersection of the $\mathrm{H}_{2}$-type MOs of methane symmetry, and in similar geometries such as that of $\mathrm{CH}_{3}$, representative of the general case, electron indivisibility, current continuity, and conservation of energy and angular momentum require that the current between the $C 2 s p^{3}$ shell and points of mutual contact is projected onto and flows along the radial vector to the surface of $C 2 s p^{3}$ shell. This current designated the bisector current (BC) meets the C2sp surface and does not travel to distances shorter than its radius.

Moreover, an energy minimum is obtained when the $H$-atom charge-density of each $C-H$-bond MO is decreased by a factor of 0.25 with a corresponding 0.25 increase in that of the three other $C-H$-bond MOs. In this case, the angular momentum components of the transferred current mutually cancel. The geometry of the equivalent bonds is tetrahedral. The symmetry point group is $T_{d}$. This geometry is equivalent to the indistinguishable bonds positioned uniformly on a spherical surface or also at the apexes of a cube. The predicted angle $\theta$ between the $C-H$ bonds is:

$$
\begin{equation*}
\theta=109.5^{\circ} \tag{13.595}
\end{equation*}
$$

The experimental bond angle is [41]:

$$
\begin{equation*}
\theta=109.5^{\circ} \tag{13.596}
\end{equation*}
$$

The polar angle $\phi$ at which the $H_{2}$-type ellipsoidal MOs intersect is given by the bisector of the angle $\theta$ between the $C-H$ bonds:

$$
\begin{equation*}
\phi=\frac{109.5}{2}=54.75^{\circ} \tag{13.597}
\end{equation*}
$$

With the carbon nucleus defined as the origin and one of the $C-H$ bonds defined as the positive x -axis, the polar-coordinate angle of the intersection occurs at:

$$
\begin{equation*}
\phi^{\prime}=54.75^{\circ}+180^{\circ}=234.75^{\circ} \tag{13.598}
\end{equation*}
$$

The polar radius $r_{i}$ at this angle is given by Eqs. (13.84-13.85):

$$
\begin{equation*}
r_{i}=\left(a-c^{\prime}\right) \frac{1+\frac{c^{\prime}}{a}}{1+\frac{c^{\prime}}{a} \cos \phi^{\prime}} \tag{13.599}
\end{equation*}
$$

Substitution of Eqs. (13.584-13.585) and (13.589) into Eq. (13.599) gives:

$$
\begin{equation*}
r_{i}=1.52223 a_{0}=8.05530 \times 10^{-11} \mathrm{~m} \tag{13.600}
\end{equation*}
$$

Using the orbital composition of $\mathrm{CH}_{4}$ (Eq. (13.579)), the radii of $C 1 s=0.17113 a_{0}$ (Eq. (10.51)) and $C 2 s p^{3}=0.91771 a_{0}$ (Eq. (13.424)) shells, and the parameters of the $\mathrm{CH}_{4} \mathrm{MO}$ given by Eqs. (13.3-13.4), (13.584-13.586), and (13.588-13.600), the charge-density of the $\mathrm{CH}_{4} \mathrm{MO}$ comprising the linear combination of four $\mathrm{C}-\mathrm{H}$-bond MOs is shown in Figure 13.13. Each $C-H$-bond MO having the dimensional diagram shown in Figure 13.9 comprises a $H_{2}$-type ellipsoidal MO and a $C 2 s p^{3} \mathrm{HO}$ according to Eq. (13.579). But, based on the $T_{d}$ symmetry of the $H_{2}$-type MOs, the charge is distributed 1:1 between the $H_{2}$ type MOs and the $C 2 s p^{3}$ shell.

Figure 13.13. $\mathrm{CH}_{4} \mathrm{MO}$ comprising the linear combination of four $\mathrm{C}-\mathrm{H}$-bond MOs formed by the superposition of a $\mathrm{H}_{2}$ type ellipsoidal MO and a $\mathrm{C} 2 s p^{3} \mathrm{HO}$. (A) Color scale, translucent view of the charge-density of the $\mathrm{CH}_{4} \mathrm{MO}$. The combined surface of the four $H_{2}$-type ellipsoidal MOs from each $C-H$ bond that surrounds the $C 2 s p^{3} \mathrm{HO}$, the $C 2 s p^{3} \mathrm{HO}$ shell, $C 1 s$ shell, and the nuclei (red, not to scale) are shown. (B) Off-center cut-away view showing the complete inner most $C 1 s$ shell, and moving radially, the $C 2 s p^{3}$ shell, and the $H_{2}$-type ellipsoidal MOs that surround the $C 2 s p^{3}$ HO. Bisector current not shown. (C) Opaque view. (D)-(E) Additional translucent views.

## ENERGIES OF $\mathrm{CH}_{4}$

The energies of $\mathrm{CH}_{4}$ are four times those of CH and are given by the substitution of the semiprincipal axes (Eqs. (13.58413.585 ) and (13.588)) into the energy equations Eq. (13.580) and (Eqs. (13.449-13.452)) that are multiplied by four:

$$
\begin{align*}
& V_{e}=4(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-145.86691 \mathrm{eV}  \tag{13.601}\\
& V_{p}=\frac{4 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=52.31390 \mathrm{eV}  \tag{13.602}\\
& T=4(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=44.92637 \mathrm{eV}  \tag{13.603}\\
& V_{m}=4(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-22.46318 \mathrm{eV}  \tag{13.604}\\
& E_{T}\left(C H_{4}\right)=-\frac{4 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV}  \tag{13.605}\\
& \quad=-85.72472 \mathrm{eV}
\end{align*}
$$

where $E_{T}\left(\mathrm{CH}_{4}\right)$ is given by Eq. (13.580) which is reiteratively matched to Eq. (13.581) within five-significant-figure round-off error.

## VIBRATION OF $\mathrm{CH}_{4}$

The vibrational energy levels of $\mathrm{CH}_{4}$ may be solved as four equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [2] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERMS OF ${ }^{12} \mathrm{CH}_{4}$

The reentrant oscillation of hybridized orbitals in the transition state is not coupled. Therefore, the equations of the radiation reaction force of methane are the same as those of $\mathrm{OH}, \mathrm{CH}, \mathrm{CH}_{2}$, and $\mathrm{CH}_{3}$ with the substitution of the methane parameters. Using Eqs. (11.136) and (13.140-13.142), the angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=2.57338 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{13.606}
\end{equation*}
$$

where $b$ is given by Eq. (13.588). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 2.57338 \times 10^{16} \mathrm{rad} / \mathrm{s}=16.93841 \mathrm{eV} \tag{13.607}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each $H_{2}$-type MO, for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.607) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of each of the four bonds for the reentrant orbit:

$$
\begin{align*}
\bar{E}_{D} & \cong E_{h v} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}} \\
& =-31.63537 \mathrm{eV} \sqrt{\frac{2 e(16.93841 \mathrm{eV})}{m_{e} c^{2}}}=-0.25758 \mathrm{eV} \tag{13.608}
\end{align*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of $\mathrm{CH}_{4}$ due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.608) and $\bar{E}_{K v i b}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of each $C-H$ bond. Using $\omega_{e}$ given by Eq. (13.458) for $\bar{E}_{\text {Kvib }}$ of the transition state having four independent bonds, $\bar{E}^{\prime}{ }_{o s c}\left({ }^{12} \mathrm{CH}_{4}\right)$ per bond is:

$$
\begin{align*}
& \bar{E}_{\text {osc }}^{\prime}\left({ }^{12} \mathrm{CH}_{4}\right)=\bar{E}_{D}+\bar{E}_{\text {Kvib }}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.609}\\
& \bar{E}_{o s c}^{\prime}\left({ }^{12} \mathrm{CH}_{4}\right)=-0.25758 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})=-0.07992 \mathrm{eV} \tag{13.610}
\end{align*}
$$

The reentrant orbit for the binding of a hydrogen atom to a $\mathrm{CH}_{3}$ radical involves four $\mathrm{C}-\mathrm{H}$ bonds. Since the vibration and reentrant oscillation is along four bonds, $\bar{E}_{\text {osc }}$ for ${ }^{12} \mathrm{CH}_{4}, \bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{4}\right)$, is:

$$
\begin{align*}
\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{4}\right) & =4\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)  \tag{13.611}\\
& =4\left(-0.25758 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})\right)=-0.31967 \mathrm{eV}
\end{align*}
$$

## TOTAL AND BOND ENERGIES OF ${ }^{12} \mathrm{CH}_{4}$

$E_{T+o s c}\left({ }^{12} \mathrm{CH}_{4}\right)$, the total energy of the ${ }^{12} \mathrm{CH}_{4}$ radical including the Doppler term, is given by the sum of $E_{T}\left(\mathrm{CH}_{4}\right)$ (Eq. (13.582)) and $\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{4}\right)$ given by Eq. (13.611).

$$
\begin{align*}
& E_{T+\text { osc }}\left(\mathrm{CH}_{4}\right)=V_{e}+T+V_{m}+V_{p}+E\left(\mathrm{C}, 2 s p^{3}\right)+\bar{E}_{\text {osc }}\left({ }^{(12} \mathrm{CH}_{4}\right)=E_{T}\left(\mathrm{CH}_{4}\right)+\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{4}\right)  \tag{13.612}\\
& E_{T+\text { osc } c}\left({ }^{12} \mathrm{CH}_{4}\right)=\left\{\begin{array}{l}
\left(\frac{-4 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.63489 \mathrm{eV}\right) \\
-4(31.63536831 \mathrm{eV}) \sqrt{\frac{2 \hbar \sqrt{\frac{3}{\frac{3}{4} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}}}{m_{e}}}-\frac{1}{m_{e} c^{2}} \hbar \sqrt{\frac{k}{\mu}}
\end{array}\right\}  \tag{13.613}\\
& =-85.72406 \mathrm{eV}-4\left(0.25758 \mathrm{eV}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{align*}
$$

From Eqs. (13.609-13.613), the total energy of ${ }^{12} \mathrm{CH}_{4}$ is:

$$
\begin{align*}
E_{T+o s c}\left({ }^{12} \mathrm{CH}_{4}\right) & =-85.72406 \mathrm{eV}+\bar{E}_{\text {osc }}\left({ }^{12} \mathrm{CH}_{4}\right) \\
& =-85.72406 \mathrm{eV}-4\left(0.25758 \mathrm{eV}-\frac{1}{2}(0.35532 \mathrm{eV})\right)=-86.04373 \mathrm{eV} \tag{13.614}
\end{align*}
$$

where $\omega_{e}$ given by Eq. (13.458) was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The $\mathrm{CH}_{4}$ bond dissociation energy, $E_{D}\left({ }^{12} \mathrm{CH}_{4}\right)$, is given by the sum of the total energies of the $\mathrm{CH}_{3}$ radical and the hydrogen atom minus $E_{T \text { tosc }}\left({ }^{12} \mathrm{CH}_{4}\right)$ :

$$
\begin{equation*}
E_{D}\left({ }^{12} \mathrm{CH}_{4}\right)=E\left({ }^{12} \mathrm{CH}_{3}\right)+E(H)-E_{T+\text { osc }}\left({ }^{12} \mathrm{CH}_{4}\right) \tag{13.615}
\end{equation*}
$$

where $E_{T}\left({ }^{12} \mathrm{CH}_{3}\right)$ is given by the sum of the energies of the $C 2 s p^{3} \mathrm{HO}, E\left(C, 2 s p^{3}\right)$ given by Eq. (13.428), $3 E_{D}(H)$ given by Eq. (13.154), and the negative of the bond energies of ${ }^{12} \mathrm{CH}$ given by Eq. (13.489), ${ }^{12} \mathrm{CH}_{2}$ given by Eq. (13.528), and ${ }^{12} \mathrm{CH}_{3}$ given by Eq. (13.573):

$$
\begin{equation*}
E\left({ }^{12} \mathrm{CH}_{3}\right)=\binom{3(-13.59844 \mathrm{eV})-14.63489 \mathrm{eV}}{-3.47 \mathrm{eV}-4.33064 \mathrm{eV}-4.72444 \mathrm{eV}}=-67.95529 \mathrm{eV} \tag{13.616}
\end{equation*}
$$

Thus, the ${ }^{12} \mathrm{CH}_{4}$ bond dissociation energy, $E_{D}\left({ }^{(12} \mathrm{CH}_{4}\right)$, given by Eqs. (13.154), and (13.614-13.616) is:

$$
\begin{align*}
E_{D}\left({ }^{12} \mathrm{CH}_{4}\right) & =-(67.95529 \mathrm{eV}+13.59844 \mathrm{eV})-E_{T+\text { osc }}\left({ }^{12} \mathrm{CH}_{4}\right)  \tag{13.617}\\
& =-81.55373 \mathrm{eV}-(-86.04373 \mathrm{eV})=4.4900 \mathrm{eV}
\end{align*}
$$

The experimental ${ }^{12} \mathrm{CH}_{4}$ bond dissociation energy is [40] :

$$
\begin{equation*}
E_{D}\left({ }^{12} \mathrm{CH}_{4}\right)=4.48464 \mathrm{eV} \tag{13.618}
\end{equation*}
$$

The results of the determination of bond parameters of $\mathrm{CH}_{4}$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## NITROGEN MOLECULE

The nitrogen molecule can be formed by the reaction of two nitrogen atoms:

$$
\begin{equation*}
N+N \rightarrow N_{2} \tag{13.619}
\end{equation*}
$$

The bond in the nitrogen molecule comprises a $H_{2}$-type molecular orbital (MO) with two paired electrons. The force balance equation and radius $r_{7}$ of the $2 p$ shell of $N$ is derived in the Seven-Electron Atoms section. With the formation of the $H_{2}$-type MO by the contribution of a $2 p$ electron from each $N$ atom, a diamagnetic force arises between the remaining $2 p$ electrons and the $H_{2}$-type MO. This force from each $N$ causes the $H_{2}$-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the integer increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining $2 p$ electrons of each $N$ decrease the radius of the corresponding shell such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of $N_{2}$ is $1 s_{1}^{2} 1 s_{2}^{2} 2 s_{1}^{2} 2 s_{2}^{2} 2 p_{1}^{2} 2 p_{2}^{2} \sigma_{1,2}^{2}$ where the subscript designates the $N$ atom, 1 or $2, \sigma$ designates the $H_{2}$-type MO, and the orbital arrangement is:

Nitrogen is predicted to be diamagnetic in agreement with observations.

## FORCE BALANCE OF THE $2 p$ SHELL OF THE NITROGEN ATOMS OF THE NITROGEN MOLECULE

For each $N$ atom, force balance for the outermost $2 p$ electron of $N_{2}$ (electron 6) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 6 and the other $2 p$-shell as well as the $2 s$ shell electrons due to spin and orbital angular momentum. The forces used are derived in the Seven-Electron Atoms section. The central Coulomb force on the outer-most $2 p$ shell electron of $N_{2}$ (electron 6) due to the nucleus and the inner five electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{\text {ele }}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}} \mathbf{i}_{\mathbf{r}} \tag{13.621}
\end{equation*}
$$

for $r>r_{5}$. The $2 p$ shell possess an external electric field given by Eq. (10.92) for $r>r_{6}$. The energy is minimized with conservation of angular momentum. This condition is met when the diamagnetic force, $\mathbf{F}_{\text {diamagnetic }}$, of Eq. (10.82) due to the $p$ orbital contribution is the same as that of the reactant nitrogen atoms given by Eq. (10.136) with $r_{6}$ replacing $r_{7}$ :

$$
\begin{align*}
\mathbf{F}_{\text {diamagnetic }} & =-\left(\frac{1}{3}\right) \frac{\hbar^{2}}{4 m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \\
& =-\frac{\hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}} \mathbf{i}_{\mathbf{r}} \tag{13.622}
\end{align*}
$$

And, $\mathbf{F}_{\operatorname{mag} 2}$ corresponding to the conserved orbital angular momentum of the three orbitals is given by Eq. (10.89).

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 2}=\frac{1}{Z} \frac{3 \hbar^{2}}{m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.623}
\end{equation*}
$$

The electric field external to the $2 p$ shell given by Eq. (10.92) for $r>r_{6}$ gives rise to a second diamagnetic force,
$\mathbf{F}_{\text {diamagnetic 2 }}$, given by Eq. (10.93). $\mathbf{F}_{\text {diamagnetic } 2}$ due to the binding of the p-orbital electron having an electric field of +1 outside of its radius is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 2}=-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{m_{e} r_{6}^{4}} 10 \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.624}
\end{equation*}
$$

In addition, the contribution of a $2 p$ electron from each $N$ atom in the formation of the $\sigma$ MO gives rise to a paramagnetic force on the remaining two $2 p$ electrons that pair. The force, $\mathbf{F}_{\text {mag } 3}$, follows from Eq. (10.11) wherein the two radii are equal to $r_{6}$ and the direction is positive, central:

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 3}=\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathrm{r}} \tag{13.625}
\end{equation*}
$$

$\mathbf{F}_{\text {mag } 3}$ is present in additional diatomic molecules where its contribution minimizes the energy. This AO spin-pairing force reduces the radius directly to reduce the energy, and it can also cancel the contribution of the corresponding electron to $\mathbf{F}_{\text {diamagnetic }}$ to further reduce the energy.

The radius of the $2 p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.621)) and diamagnetic (Eqs. (13.622) and (13.624)), and paramagnetic (Eqs. (13.623) and (13.625)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{6}^{2}}{r_{6}}=\binom{\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}}-\frac{\hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)}+\frac{3 \hbar^{2}}{Z m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)}}{-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{6}^{4} m_{e}} 10 \sqrt{s(s+1)}+\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{s(s+1)}} \tag{13.626}
\end{equation*}
$$

Substitution of $v_{6}=\frac{\hbar}{m_{e} r_{6}}$ (Eq. (1.35)) and $s=\frac{1}{2}$ into Eq. (13.626) gives:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} r_{6}^{3}}-\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{\frac{3}{4}}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}}-\frac{\hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{3 \hbar^{2}}{Z m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}}-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{6}^{4} m_{e}} 10 \sqrt{\frac{3}{4}} \tag{13.627}
\end{equation*}
$$

The quadratic equation corresponding to Eq. (13.627) is:

$$
\begin{equation*}
r_{6}^{2}-\frac{\frac{\hbar^{2}}{m_{e}}\left(1-\frac{\sqrt{3}}{8}\right)}{\left(\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)^{2}} r_{6}-\frac{\frac{\hbar^{2}}{m_{e}}\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3} 10 \sqrt{\frac{3}{4}}}{\left(\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)}=0 \tag{13.628}
\end{equation*}
$$

The solution of Eq. (13.628) using the quadratic formula is:

$$
\begin{equation*}
r_{6}=\frac{a_{0}\left(1-\frac{\sqrt{3}}{8}\right)}{\left((Z-5)-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)} \pm a_{0} \sqrt{\left(\frac{1-\frac{\sqrt{3}}{8}}{\left(\frac{\left.(Z-5)-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}{\left(\frac{2}{2} \sqrt{3}\left(\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3}\right)\right.}\right.}\right)^{2}} \sqrt{2}, r_{3} \text { in units of } a_{0} \tag{13.629}
\end{equation*}
$$

The positive root of Eq. (13.629) must be taken in order that $r_{6}>0$. Substitution of $\frac{r_{3}}{a_{0}}=0.69385$ (Eq. (10.62) with $Z=7$ ) into Eq. (13.629) gives:

$$
\begin{equation*}
r_{6}=0.78402 a_{0} \tag{13.630}
\end{equation*}
$$

## ENERGIES OF THE $2 p$ SHELL OF THE NITROGEN ATOMS OF THE NITROGEN MOLECULE

The central forces on the $2 p$ shell of each $N$ are increased with the formation of the $\sigma \mathrm{MO}$, which reduces the shell's radius and increases its total energy. The Coulombic energy terms of the total energy of the two $N$ atoms at the new radius are calculated and added to the energy of the $\sigma$ MO to give the total energy of $N_{2}$. Then, the bond energy is determined from the total $N_{2}$ energy.

The radius $r_{7}$ of each nitrogen atom before bonding is given by Eq. (10.142).

$$
\begin{equation*}
r_{7}=0.93084 a_{0} \tag{13.631}
\end{equation*}
$$

Using the initial radius $r_{7}$ of each $N$ atom and the final radius $r_{6}$ of the $N 2 p$ shell of $N_{2}$ (Eq. (13.630)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_{T}\left(N_{2}, 2 p\right)$ of the Coulombic energy change of the $N 2 p$ electrons of both atoms is determined using Eq. (10.102).

$$
\begin{equation*}
E_{T}\left(N_{2}, 2 p\right)=-2 \sum_{n=4}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{6}}-\frac{1}{r_{7}}\right)=-2(13.60580 \mathrm{eV})(0.20118)(2+3)=-27.37174 \mathrm{eV} \tag{13.632}
\end{equation*}
$$

## FORCE BALANCE OF THE $\sigma$ MO OF THE NITROGEN MOLECULE

The $2 p$ shell gives rise to two diamagnetic forces on the $\sigma$ MO. As given for the hydrogen molecule in the Hydrogen-Type Molecules section, the $\sigma$ MO comprises two electrons, $\sigma$ electron 1 and $\sigma$ electron 2 , that are bound at $\xi=0$ as a equipotential prolate spheroidal MO by the central Coulombic field due to the nitrogen atoms at the foci and the spin pairing force on $\sigma$ electron 2 due to $\sigma$ electron 1 that initially has smaller semiprincipal axes. The spin-pairing force given in Eq. (11.200) is equal to one half the centrifugal force of the two electrons. The spin-pairing electron of the $\sigma$ MO is also repelled by the remaining $2 p$ electrons of each $N$ according to Lenz law, and the force is based on the total number of these electrons $n_{e}$ that interact with the binding $\sigma-\mathrm{MO}$ electron. This diamagnetic force $\mathbf{F}_{\text {diamagneticMO1 }}$ is of the same form as the molecular spinpairing force but in the opposite direction. The force follows from the derivations of Eqs. (10.219) and (11.200) which gives:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO1 }}=\frac{n_{e} \hbar^{2}}{4 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{13.633}
\end{equation*}
$$

In addition, there is a relativistically corrected Lorentz force $\mathbf{F}_{\text {diamagneticMO2 }}$ on the pairing electron of the $\sigma$ MO that follows from Eqs. (7.15) and (11.200):

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO2 }}=\frac{1}{Z} \frac{|L| \hbar}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{13.634}
\end{equation*}
$$

where $|L|$ is the magnitude of the angular momentum of each $N$ atom at a focus that is the source of the diamagnetism at the $\sigma$ MO.

The force balance equation for the $\sigma-\mathrm{MO}$ of the nitrogen molecule given by Eq. (11.200) and Eqs. (13.633-13.634) with $n_{e}=2$ and $|L|=\hbar$ is:

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(1+\frac{1}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{13.635}\\
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D-\frac{1}{Z} \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{13.636}\\
& \left(2+\frac{1}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D  \tag{13.637}\\
& a=\left(2+\frac{1}{Z}\right) a_{0} \tag{13.638}
\end{align*}
$$

Substitution of $Z=7$ into Eq. (13.638) gives:

$$
\begin{equation*}
a=2.14286 a_{0}=1.13395 \times 10^{-10} \mathrm{~m} \tag{13.639}
\end{equation*}
$$

Substitution of Eq. (13.639) into Eq. (11.79) is:

$$
\begin{equation*}
c^{\prime}=1.03510 a_{0}=5.47750 \times 10^{-11} \mathrm{~m} \tag{13.640}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.640) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.07020 a_{0}=1.09550 \times 10^{-10} \mathrm{~m} \tag{13.641}
\end{equation*}
$$

The experimental bond distance from Ref. [28] and Ref. [43] is:

$$
\begin{align*}
& 2 c^{\prime}=1.09769 \times 10^{-10} \mathrm{~m}  \tag{13.642}\\
& 2 c^{\prime}=1.094 \times 10^{-10} \mathrm{~m} \tag{13.643}
\end{align*}
$$

Substitution of Eqs. (13.639-13.640) into Eq. (11.80) is:

$$
\begin{equation*}
b=c=1.87628 a_{0}=9.92882 \times 10^{-11} \mathrm{~m} \tag{13.644}
\end{equation*}
$$

Substitution of Eqs. (13.639-13.640) into Eq. (11.67) is:

$$
\begin{equation*}
e=0.48305 \tag{13.645}
\end{equation*}
$$

Using the electron configuration of $N_{2}$ (Eq. (13.620)), the radii of the $N 1 s=0.14605 a_{0}$ (Eq. (10.51)), $N 2 s=0.69385 a_{0}$ (Eq. (10.62)), and $N 2 p=0.78402 a_{0}$ (Eq. (13.630)) shells and the parameters of the $\sigma \mathrm{MO}$ of $N_{2}$ given by Eqs. (13.3-13.4), (13.639-13.641), and (13.644-13.645), the dimensional diagram and charge-density of the $N_{2} \mathrm{MO}$ are shown in Figures 13.14 and 13.15 , respectively.

Despite the predictions of standard quantum mechanics that preclude the imaging of a molecular orbital, the full threedimensional structure of the outer molecular orbital of $N_{2}$ has been recently tomographically reconstructed [44]. The chargedensity surface observed is consistent with that shown in Figure 13.15. This result constitutes direct evidence that electrons are not point-particle probability waves that have no form until they are "collapsed to a point" by measurement. Rather they are physical, two-dimensional equipotential charge density surfaces.

Figure 13.14. The cross section of the $N_{2}$ MO showing the axes, $\sigma$ MO ( $H_{2}$-type ellipsoidal MO), with the $N 1 s, 2 s$, and $2 p$ atomic orbitals (AOs). Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $r_{6}$ : radius of the $N 2 p$ shell having two paired electrons.

Figure 13.15. $N_{2} \mathrm{MO}$ comprising the $\sigma \mathrm{MO}\left(\mathrm{H}_{2}\right.$-type MO) with N atoms at the foci that have each donated an electron to the $\sigma$ MO and have smaller radii and higher binding energies as a consequence. (A) Color scale, translucent view of the charge-density of the $N_{2}$ MO. (B) Off-center cutaway view showing the complete inner most $N 1 s$ shell, and moving radially, the $N 2 s$ shell, the $N 2 p$ shell, and the $\sigma$ prolate spheroidal MO that have the $N$ atoms as the foci.

## SUM OF THE ENERGIES OF THE $\sigma$ MO AND THE AOs OF THE NITROGEN MOLECULE

The energies of the $N_{2} \sigma$ MO are given by the substitution of the semiprincipal axes (Eqs. (13.639-13.640) and (13.644)) into the energy equations (Eqs. (11.207-11.212)) of $\mathrm{H}_{2}$ :

$$
\begin{align*}
& V_{e}=\frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-27.70586 \mathrm{eV}  \tag{13.646}\\
& V_{p}=\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=13.14446 \mathrm{eV}  \tag{13.647}\\
& T=\frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=6.46470 \mathrm{eV}  \tag{13.648}\\
& V_{m}=\frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-3.23235 \mathrm{eV}  \tag{13.649}\\
& E_{T}=V_{e}+T+V_{m}+V_{p} \tag{13.650}
\end{align*}
$$

Substitution of Eqs. (11.79) and (13.646-13.649) into Eq. (13.650) gives:

$$
\begin{aligned}
E_{T}\left(N_{2}, \sigma\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right) \\
& =-11.32906 \mathrm{eV}
\end{aligned}
$$

where $E_{T}\left(N_{2}, \sigma\right)$ is the total energy of the $\sigma$ MO of $N_{2}$. The sum, $E_{T}\left(N_{2}\right)$, of $E_{T}\left(N_{2}, 2 p\right)$, the $2 p(\mathrm{AO})$ contribution given by Eq. (13.632), and $E_{T}\left(N_{2}, \sigma\right)$, the $\sigma$ MO contribution given by Eq. (13.651) is:

$$
\begin{align*}
E_{T}\left(N_{2}\right) & =E_{T}\left(N_{2}, 2 p\right)+E_{T}\left(N_{2}, \sigma\right)  \tag{13.652}\\
& =-27.37174 \mathrm{eV}-11.32906 \mathrm{eV}=-38.70080 \mathrm{eV}
\end{align*}
$$

## VIBRATION OF $N_{2}$

The vibrational energy levels of $N_{2}$ may be solved by determining the Morse potential curve from the energy relationships for the transition from two $N$ atoms whose parameters are given by Eqs. (10.134-10.143) to the two $N$ atoms whose parameter $r_{6}$ is given by Eq. (13.630) and the $\sigma$ MO whose parameters are given by Eqs. (13.639-13.641) and (13.644-13.645). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K\&P) [15] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

## THE DOPPLER ENERGY TERMS OF THE NITROGEN MOLECULE

The equations of the radiation reaction force of nitrogen are the same as those of $H_{2}$ with the substitution of the nitrogen parameters. Using Eqs. (11.231-11.233), the angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{align*}
\omega & =\sqrt{\frac{e^{2}}{\frac{4 \pi \varepsilon_{0} a^{3}}{m_{e}}}}  \tag{13.653}\\
& =1.31794 \times 10^{16} \mathrm{rad} / \mathrm{s}
\end{align*}
$$

where $a$ is given by Eq. (13.639). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{align*}
\bar{E}_{K} & =\hbar \omega  \tag{13.654}\\
& =\hbar 1.31794 \times 10^{16} \mathrm{rad} / \mathrm{s}=8.67490 \mathrm{eV}
\end{align*}
$$

In Eq. (11.181), substitution of $E_{T}\left(N_{2}\right)$ for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.654) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of the reentrant orbit:

$$
\begin{align*}
\bar{E}_{D} & \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}  \tag{13.655}\\
& =-38.70080 \mathrm{eV} \sqrt{\frac{2 e(8.67490 \mathrm{eV})}{m_{e} c^{2}}}=-0.22550 \mathrm{eV}
\end{align*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $N_{2} \mathrm{MO}$ due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.655) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy. Using the experimental $N_{2}$ $\omega_{e}$ of $2358.57 \mathrm{~cm}^{-1}(0.29243 \mathrm{eV})$ [28] for $\bar{E}_{\text {Kvib }}$ of the transition state, $\bar{E}_{\text {osc }}\left(N_{2}\right)$ is:

$$
\begin{align*}
\bar{E}_{\text {osc }}\left(N_{2}\right) & =\bar{E}_{D}+\bar{E}_{\text {Kvib }}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.656}\\
\bar{E}_{\text {osc }}\left(N_{2}\right) & =-0.22550 \mathrm{eV}+\frac{1}{2}(0.29243 \mathrm{eV})  \tag{13.657}\\
& =-0.07929 \mathrm{eV}
\end{align*}
$$

## TOTAL AND BOND ENERGIES OF THE NITROGEN MOLECULE

$E_{T+o s c}\left(N_{2}\right)$, the total energy of $N_{2}$ including the Doppler term, is given by the sum of $E_{T}\left(N_{2}\right)$ (Eq. (13.652)) and $\bar{E}_{\text {osc }}\left(N_{2}\right)$ given by Eq. (13.657):

$$
\begin{align*}
E_{T+\text { osc }}\left(N_{2}\right) & =V_{e}+T+V_{m}+V_{p}+E_{T}\left(N_{2}, 2 p\right)+\bar{E}_{\text {osc }}\left(N_{2}\right) \\
& =E_{T}\left(N_{2}, \sigma\right)+E_{T}\left(N_{2}, 2 p\right)+\bar{E}_{\text {osc }}\left(N_{2}\right)=E_{T}\left(N_{2}\right)+\bar{E}_{\text {osc }}\left(N_{2}\right)  \tag{13.658}\\
E_{T+\text { osc }}\left(N_{2}\right) & =\left\{\begin{array}{l}
\left(\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right)-2 \sum_{n=4}^{\frac{5}{2}}\right) \\
\left(\frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{6}}-\frac{1}{r_{7}}\right)\right) \\
\left.1+\sqrt{\frac{e^{2}}{\frac{2 \pi \varepsilon_{0} a^{3}}{m_{e}}}}\right)+\frac{1}{m_{e} c^{2}} \hbar \sqrt{\frac{k}{\mu}}
\end{array}\right\}  \tag{13.659}\\
& =-38.70080 e V-0.22550 e V+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}
\end{align*}
$$

From Eqs. (13.656-13.659), the total energy of the $N_{2} \mathrm{MO}$ is:

$$
\begin{align*}
E_{T+o s c}\left(N_{2}\right) & =-38.70080 \mathrm{eV}+\bar{E}_{\text {osc }}\left(N_{2}\right) \\
& =-38.70080 \mathrm{eV}-0.22550 \mathrm{eV}+\frac{1}{2}(0.29243 \mathrm{eV})=-38.78009 \mathrm{eV} \tag{13.660}
\end{align*}
$$

where the experimental $\omega_{e}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The $N_{2}$ bond dissociation energy, $E_{D}\left(N_{2}\right)$, is given by the difference in the total energies of the two $N$ atoms and $E_{T+o s c}\left(N_{2}\right)$ :

$$
\begin{equation*}
E_{D}\left(N_{2}\right)=2 E(N)-E_{T+o s c}\left(N_{2}\right) \tag{13.661}
\end{equation*}
$$

where the energy of a nitrogen atom is [6] :

$$
\begin{equation*}
E(N)=-14.53414 \mathrm{eV} \tag{13.662}
\end{equation*}
$$

Thus, the $N_{2}$ bond dissociation energy, $E_{D}\left(N_{2}\right)$, given by Eqs. (13.660-13.662) is:

$$
\begin{equation*}
E_{D}\left(N_{2}\right)=-2(14.53414 \mathrm{eV})-E_{T+o s c}\left(N_{2}\right)=-29.06828 \mathrm{eV}-(-38.78009 \mathrm{eV})=9.71181 \mathrm{eV} \tag{13.663}
\end{equation*}
$$

The experimental $N_{2}$ bond dissociation energy from Ref. [43] and Ref. [45] is:

$$
\begin{align*}
& E_{D}\left(N_{2}\right)=9.756 \mathrm{eV}  \tag{13.664}\\
& E_{D}\left(N_{2}\right)=9.764 \mathrm{eV} \tag{13.665}
\end{align*}
$$

The results of the determination of bond parameters of $N_{2}$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## OXYGEN MOLECULE

The oxygen molecule can be formed by the reaction of two oxygen atoms:

$$
\begin{equation*}
\mathrm{O}+\mathrm{O} \rightarrow \mathrm{O}_{2} \tag{13.666}
\end{equation*}
$$

The bond in the oxygen molecule comprises a $H_{2}$-type molecular orbital (MO) with two paired electrons. The force balance equation and radius $r_{8}$ of the $2 p$ shell of $O$ is derived in the Eight-Electron Atoms section. With the formation of the $H_{2}$-type MO by the contribution of a $2 p$ electron from each $O$ atom, a diamagnetic force arises between the remaining $2 p$ electrons and the $H_{2}$-type MO. This force from each O causes the $\mathrm{H}_{2}$-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the integer increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining $2 p$ electrons of each $O$ decrease the radius of the corresponding shell such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of $O_{2}$ is $1 s_{1}^{2} 1 s_{2}^{2} 2 s_{1}^{2} 2 s_{2}^{2} 2 p_{1}^{3} 2 p_{2}^{3} \sigma_{1,2}^{2}$ where the subscript designates the $O$ atom, 1 or $2, \sigma$ designates the $H_{2}$-type MO, and the orbital arrangement is:

Oxygen is predicted to be paramagnetic in agreement with observations [42].

## FORCE BALANCE OF THE $2 p$ SHELL OF THE OXYGEN ATOMS OF THE OXYGEN MOLECULE

For each $O$ atom, force balance for the outermost $2 p$ electron of $O_{2}$ (electron 7) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 7 and the other $2 p$-shell as well as the $2 s$ shell electrons due to spin and orbital angular momentum. The forces used are derived in the Eight-Electron Atoms section. The central Coulomb force on the outer-most $2 p$ shell electron of $O_{2}$ (electron 7) due to the nucleus and the inner six electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{\text {ele }}=\frac{(Z-6) e^{2}}{4 \pi \varepsilon_{0} r_{7}^{2}} \mathbf{i}_{\mathbf{r}} \tag{13.668}
\end{equation*}
$$

for $r>r_{6}$. The $2 p$ shell possess an external electric field given by Eq. (10.92) for $r>r_{7}$. The energy is minimized with conservation of angular momentum. This condition is met when the magnetic forces are the same as those of the reactant oxygen atoms with $r_{7}$ replacing $r_{8}$. The diamagnetic force, $\mathbf{F}_{\text {diamagnetic }}$, of Eq. (10.82) due to the $p$-orbital contributions is given by Eq. (10.156):

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic }}=-\left(\frac{1}{3}+\frac{2}{3}\right) \frac{\hbar^{2}}{4 m_{e} r_{7}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}}=-\frac{3 \hbar^{2}}{12 m_{e} r_{7}^{2} r_{3}} \sqrt{\frac{3}{4}} \mathbf{i}_{\mathbf{r}} \tag{13.669}
\end{equation*}
$$

And, $\mathbf{F}_{\text {mag } 2}$ corresponding to the conserved spin and orbital angular momentum given by Eq. (10.157) is:

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 2}=\frac{1}{Z} \frac{2 \hbar^{2}}{m_{e} r_{7}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.670}
\end{equation*}
$$

The electric field external to the $2 p$ shell given by Eq. (10.92) for $r>r_{7}$ gives rise to a second diamagnetic force, $\mathbf{F}_{\text {diamagnetic 2 }}$, given by Eq. (10.93). $\mathbf{F}_{\text {diamagnetic } 2}$ due to the binding of the p-orbital electron having an electric field of +1 outside of its radius is :

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 2}=-\left[\frac{Z-7}{Z-6}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{m_{e} r_{7}^{4}} 10 \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.671}
\end{equation*}
$$

The radius of the $2 p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.688)) and diamagnetic (Eqs. (13.669) and (13.671)), and paramagnetic (Eq. (13.670)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{7}^{2}}{r_{7}}=\binom{\frac{(Z-6) e^{2}}{4 \pi \varepsilon_{0} r_{7}^{2}}-\frac{3 \hbar^{2}}{12 m_{e} r_{7}^{2} r_{3}} \sqrt{s(s+1)}+\frac{2 \hbar^{2}}{Z m_{e} r_{7}^{2} r_{3}} \sqrt{s(s+1)}}{-\left[\frac{Z-7}{Z-6}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{7}^{4} m_{e}} 10 \sqrt{s(s+1)}} \tag{13.672}
\end{equation*}
$$

Substitution of $v_{7}=\frac{\hbar}{m_{e} r_{7}}$ (Eq. (1.35)) and $s=\frac{1}{2}$ into Eq. (13.672) gives:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} r_{7}^{3}}=\frac{(Z-6) e^{2}}{4 \pi \varepsilon_{0} r_{7}^{2}}-\frac{3 \hbar^{2}}{12 m_{e} r_{7}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{2 \hbar^{2}}{Z m_{e} r_{7}^{2} r_{3}} \sqrt{\frac{3}{4}}-\left[\frac{Z-7}{Z-6}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{7}^{4} m_{e}} 10 \sqrt{\frac{3}{4}} \tag{13.673}
\end{equation*}
$$

The quadratic equation corresponding to Eq. (13.673) is:

$$
\begin{equation*}
r_{7}^{2}-\frac{\frac{\hbar^{2}}{m_{e}}}{\left(\frac{(Z-6) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{3}{12}-\frac{2}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)} r_{7}-\frac{\frac{\hbar^{2}}{m_{e}}\left[\frac{Z-7}{Z-6}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3} 10 \sqrt{\frac{3}{4}}}{\left(\frac{(Z-6) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{3}{12}-\frac{2}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)}=0 \tag{13.674}
\end{equation*}
$$

The solution of Eq. (13.674) using the quadratic formula is:

$$
\begin{equation*}
r_{7}=\frac{\sqrt{\left(\frac{a_{0}}{\left((Z-6)-\left(\frac{3}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}\right)^{2}}}{\left(\frac{\left.\left(\frac{3}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}{\left(\left(a_{0}\right)\right.} \sqrt{+\frac{20 \sqrt{3}\left(\left[\frac{Z-7}{Z-6}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3}\right)}{\left((Z-6)-\left(\frac{3}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}}\right.}, r_{3} \text { in units of } a_{0} \tag{13.675}
\end{equation*}
$$

The positive root of Eq. (13.675) must be taken in order that $r_{7}>0$. Substitution of $\frac{r_{3}}{a_{0}}=0.59020$ (Eq. (10.62) with $Z=8$ ) into Eq. (13.675) gives:

$$
\begin{equation*}
r_{7}=0.91088 a_{0} \tag{13.676}
\end{equation*}
$$

## ENERGIES OF THE $2 p$ SHELL OF THE OXYGEN ATOMS OF THE OXYGEN MOLECULE

The central forces on the $2 p$ shell of each $O$ are increased with the formation of the $\sigma \mathrm{MO}$, which reduces the shell's radius and increases its total energy. The Coulombic energy terms of the total energy of the two $O$ atoms at the new radius are calculated and added to the energy of the $\sigma$ MO to give the total energy of $O_{2}$. Then, the bond energy is determined from the total $O_{2}$ energy.

The radius $r_{8}$ of each oxygen atom before bonding is given by Eq. (10.162).

$$
\begin{equation*}
r_{8}=a_{0} \tag{13.677}
\end{equation*}
$$

Using the initial radius $r_{8}$ of each $O$ atom and the final radius $r_{7}$ of the $O 2 p$ shell of $O_{2}$ (Eq. (13.676)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_{T}\left(O_{2}, 2 p\right)$ of the Coulombic energy change of the $O 2 p$ electrons of both atoms is determined using Eq. (10.102):

$$
\begin{align*}
E_{T}\left(O_{2}, 2 p\right) & =-2 \sum_{n=4}^{6} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{7}}-\frac{1}{r_{8}}\right)  \tag{13.678}\\
& =-2(13.60580 \mathrm{eV})(0.09784)(2+3+4)=-23.96074 \mathrm{eV}
\end{align*}
$$

## FORCE BALANCE OF THE $\sigma$ MO OF THE OXYGEN MOLECULE

The force balance equation for the $\sigma$-MO of the oxygen molecule given by Eq. (11.200) and Eqs. (13.633-13.634) with $n_{e}=3$ and $|L|=\sqrt{\frac{3}{4}} \hbar$ is:

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(\frac{3}{2}+\frac{\sqrt{\frac{3}{4}}}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{13.679}\\
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D-\left(\frac{1}{2}+\frac{\sqrt{\frac{3}{4}}}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \tag{13.680}
\end{align*}
$$

$$
\begin{align*}
& \left(\frac{5}{2}+\frac{\sqrt{\frac{3}{4}}}{Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D  \tag{13.681}\\
& a=\left(\frac{5}{2}+\frac{\sqrt{\frac{3}{4}}}{Z}\right) a_{0} \tag{13.682}
\end{align*}
$$

Substitution of $Z=8$ into Eq. (13.682) gives:

$$
\begin{equation*}
a=2.60825 a_{0}=1.38023 \times 10^{-10} \mathrm{~m} \tag{13.683}
\end{equation*}
$$

Substitution of Eq. (13.683) into Eq. (11.79) is:

$$
\begin{equation*}
c^{\prime}=1.14198 a_{0}=6.04312 \times 10^{-11} \mathrm{~m} \tag{13.684}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.684) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.28397 a_{0}=1.20862 \times 10^{-10} \mathrm{~m} \tag{13.685}
\end{equation*}
$$

The experimental bond distance is [28]:

$$
\begin{equation*}
2 c^{\prime}=1.20752 \times 10^{-10} \mathrm{~m} \tag{13.686}
\end{equation*}
$$

Substitution of Eqs. (13.683-13.684) into Eq. (11.80) is:

$$
\begin{align*}
b & =c=2.34496 a_{0}  \tag{13.687}\\
& =1.24090 \times 10^{-10} \mathrm{~m}
\end{align*}
$$

Substitution of Eqs. (13.683-13.684) into Eq. (11.67) is:

$$
\begin{equation*}
e=0.43783 \tag{13.688}
\end{equation*}
$$

Using the electron configuration of $O_{2}$ (Eq. (13.667)), the radii of the $O 1 s=0.12739 a_{0}$ (Eq. (10.51)), $O 2 s=0.59020 a_{0}$ (Eq. (10.62)), and $O 2 p=0.91088 a_{0}$ (Eq. (13.676)) shells and the parameters of the $\sigma \mathrm{MO}$ of $O_{2}$ given by Eqs. (13.3-13.4), (13.68313.685), and (13.687-13.688), the dimensional diagram and charge-density of the $O_{2} \mathrm{MO}$ are shown in Figures 13.16 and 13.17, respectively.

Figure 13.16. The cross section of the $\mathrm{O}_{2}$ MO showing the axes, $\sigma$ MO ( $H_{2}$-type ellipsoidal MO), with the $O 1 s, 2 s$, and $2 p$ atomic orbitals (AOs). Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $r_{7}$ : radius of the $O 2 p$ shell having two paired electrons.

Figure 13.17. $O_{2} \mathrm{MO}$ comprising the $\sigma \mathrm{MO}\left(H_{2}\right.$-type MO) with $O$ atoms at the foci that have each donated an electron to the $\sigma \mathrm{MO}$ and have smaller radii and higher binding energies as a consequence. (A) Color scale, translucent view of the charge-density of the $O_{2}$ MO. (B) Off-center cutaway view showing the complete inner most $O 1 s$ shell, and moving radially, the $O 2 s$ shell, the $O 2 p$ shell, and the $\sigma$ prolate spheroidal MO that have the $O$ atoms as the foci.

## SUM OF THE ENERGIES OF THE $\sigma$ MO AND THE AOS OF THE OXYGEN MOLECULE

The energies of the $O_{2} \sigma$ MO are given by the substitution of the semiprincipal axes (Eqs. (13.683-13.684) and (13.687)) into the energy equations (Eqs. (11.207-11.212)) of $H_{2}$ :

$$
\begin{align*}
& V_{e}=\frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-22.37716 \mathrm{eV}  \tag{13.689}\\
& V_{p}=\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=11.91418 \mathrm{eV}  \tag{13.690}\\
& T=\frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=4.28968 \mathrm{eV}  \tag{13.691}\\
& V_{m}=\frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-2.14484 \mathrm{eV}  \tag{13.692}\\
& E_{T}=V_{e}+T+V_{m}+V_{p} \tag{13.693}
\end{align*}
$$

Substitution of Eqs. (11.79) and (13.689-13.692) into Eq. (13.693) gives:

$$
\begin{align*}
E_{T}\left(O_{2}, \sigma\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right)  \tag{13.694}\\
& =-8.31814 \mathrm{eV}
\end{align*}
$$

where $E_{T}\left(O_{2}, \sigma\right)$ is the total energy of the $\sigma$ MO of $O_{2}$. The sum, $E_{T}\left(O_{2}\right)$, of $E_{T}\left(O_{2}, 2 p\right)$, the $2 p$ AO contribution given by: Eq. (13.678), and $E_{T}\left(O_{2}, \sigma\right)$, the $\sigma$ MO contribution given by Eq. (13.694) is:

$$
\begin{equation*}
E_{T}\left(O_{2}\right)=E_{T}\left(O_{2}, 2 p\right)+E_{T}\left(O_{2}, \sigma\right)=-23.96074 \mathrm{eV}-8.31814 \mathrm{eV}=-32.27888 \mathrm{eV} \tag{13.695}
\end{equation*}
$$

## VIBRATION OF $\mathrm{O}_{2}$

The vibrational energy levels of $O_{2}$ may be solved by determining the Morse potential curve from the energy relationships for the transition from two $O$ atoms whose parameters are given by Eqs. (10.154-10.163) to the two $O$ atoms whose parameter $r_{7}$ is given by Eq. (13.676) and the $\sigma$ MO whose parameters are given by Eqs. (13.683-13.685) and (13.687-13.688). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K\&P) [15] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

## THE DOPPLER ENERGY TERMS OF THE OXYGEN MOLECULE

The equations of the radiation reaction force of oxygen are the same as those of $H_{2}$ with the substitution of the oxygen parameters. Using Eqs. (11.231-11.233), the angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}=9.81432 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{13.696}
\end{equation*}
$$

where $a$ is given by Eq. (13.683). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 9.81432 \times 10^{16} \mathrm{rad} / \mathrm{s}=6.45996 \mathrm{eV} \tag{13.697}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(O_{2}\right)$ for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.697) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h v} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-32.27888 \mathrm{eV} \sqrt{\frac{2 e(6.45996 \mathrm{eV})}{m_{e} c^{2}}}=-0.16231 \mathrm{eV} \tag{13.698}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $O_{2} \mathrm{MO}$ due to the reentrant orbit in the transition state corresponding to simple
harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.698) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy. Using the experimental $O_{2} \omega_{e}$ of $1580.19 \mathrm{~cm}^{-1}(0.19592 \mathrm{eV})$ [28] for $\bar{E}_{\text {Kvib }}$ of the transition state, $\bar{E}_{\text {osc }}\left(O_{2}\right)$ is:

$$
\begin{align*}
& \bar{E}_{o s c}\left(O_{2}\right)=\bar{E}_{D}+\bar{E}_{\text {Kvib }}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.699}\\
& \bar{E}_{o s c}\left(O_{2}\right)=-0.16231 \mathrm{eV}+\frac{1}{2}(0.19592 \mathrm{eV})=-0.06435 \mathrm{eV} \tag{13.700}
\end{align*}
$$

## TOTAL AND BOND ENERGIES OF THE OXYGEN MOLECULE

$E_{T+o s c}\left(O_{2}\right)$, the total energy of $O_{2}$ including the Doppler term, is given by the sum of $E_{T}\left(O_{2}\right)$ (Eq. (13.695)) and $\bar{E}_{\text {osc }}\left(O_{2}\right)$ given by Eq. (13.700):

$$
\left.\begin{array}{rl}
E_{T+\text { osc }}\left(O_{2}\right) & =V_{e}+T+V_{m}+V_{p}+E_{T}\left(O_{2}, 2 p\right)+\bar{E}_{\text {osc }}\left(O_{2}\right) \\
& =E_{T}\left(O_{2}, \sigma\right)+E_{T}\left(O_{2}, 2 p\right)+\bar{E}_{\text {osc }}\left(O_{2}\right) \\
& =E_{T}\left(O_{2}\right)+\bar{E}_{\text {osc }}\left(O_{2}\right) \\
E_{T+\text { osc }}\left(O_{2}\right) & =\left\{\begin{array}{l}
\left(\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right)-2 \sum_{n=4}^{6} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{7}}-\frac{1}{r_{8}}\right)\right) \\
\left(1+\sqrt{\left.\frac{e^{2}}{2 \hbar \sqrt{\frac{4 \pi \varepsilon_{0} a^{3}}{m_{e}}}}\right)+\frac{1}{m_{e} c^{2}} \hbar \sqrt{\frac{k}{\mu}}}\right) \\
\end{array}\right)  \tag{13.702}\\
& =-32.27888 e V-0.16231 e V+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}
\end{array}\right\}
$$

From Eqs. (13.699-13.702), the total energy of the $O_{2} \mathrm{MO}$ is:

$$
\begin{align*}
E_{T+o s c}\left(O_{2}\right) & =-32.27888 \mathrm{eV}+\bar{E}_{\text {osc }}\left(O_{2}\right) \\
& =-32.27888 \mathrm{eV}-0.16231 \mathrm{eV}+\frac{1}{2}(0.19592 \mathrm{eV})  \tag{13.703}\\
& =-32.34323 \mathrm{eV}
\end{align*}
$$

where the experimental $\omega_{e}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The $O_{2}$ bond dissociation energy, $E_{D}\left(O_{2}\right)$, is given by the difference in the total energies of the two $O$ atoms and $E_{T+o s c}\left(O_{2}\right)$ :

$$
\begin{equation*}
E_{D}\left(O_{2}\right)=2 E(O)-E_{T+o s c}\left(O_{2}\right) \tag{13.704}
\end{equation*}
$$

where the energy of an oxygen atom is [6]:

$$
\begin{equation*}
E(O)=-13.61806 \mathrm{eV} \tag{13.705}
\end{equation*}
$$

Thus, the $O_{2}$ bond dissociation energy, $E_{D}\left(O_{2}\right)$, given by Eqs. (13.703-13.705) is:

$$
\begin{equation*}
E_{D}\left(O_{2}\right)=-2(13.61806 \mathrm{eV})-E_{T+o s c}\left(O_{2}\right)=-27.23612 \mathrm{eV}-(-32.34323 \mathrm{eV})=5.10711 \mathrm{eV} \tag{13.706}
\end{equation*}
$$

The experimental $\mathrm{O}_{2}$ bond dissociation energy from Ref. [46] and Ref. [47] is:

$$
\begin{align*}
& E_{D}\left(O_{2}\right)=5.11665 \mathrm{eV}  \tag{13.707}\\
& E_{D}\left(O_{2}\right)=5.116696 \mathrm{eV} \tag{13.708}
\end{align*}
$$

The results of the determination of bond parameters of $O_{2}$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## FLUORINE MOLECULE

The fluorine molecule can be formed by the reaction of two fluorine atoms:

$$
\begin{equation*}
F+F \rightarrow F_{2} \tag{13.709}
\end{equation*}
$$

The bond in the fluorine molecule comprises a $H_{2}$-type molecular orbital (MO) with two paired electrons. The force balance equation and radius $r_{9}$ of the $2 p$ shell of $F$ is derived in the Nine-Electron Atoms section. With the formation of the $H_{2}$-type MO by the contribution of a $2 p$ electron from each $F$ atom, a diamagnetic force arises between the remaining $2 p$ electrons and the $H_{2}$-type MO. This force from each $F$ causes the $H_{2}$-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the integer increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining $2 p$ electrons of each $F$ decrease the radius of the corresponding shell such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of $F_{2}$ is $1 s_{1}^{2} 1 s_{2}^{2} 2 s_{1}^{2} 2 s_{2}^{2} 2 p_{1}^{4} 2 p_{2}^{4} \sigma_{1,2}^{2}$ where the subscript designates the $F$ atom, 1 or $2, \sigma$ designates the $H_{2}$-type MO, and the orbital arrangement is:

Fluorine is predicted to be diamagnetic in agreement with observations [42].

## FORCE BALANCE OF THE $2 p$ SHELL OF THE FLUORINE ATOMS OF THE FLUORINE MOLECULE

For each $F$ atom, force balance for the outermost $2 p$ electron of $F_{2}$ (electron 8 ) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 8 and the other $2 p$-shell as well as the $2 s$ shell electrons due to spin and orbital angular momentum. The forces used are derived in the Nine-Electron Atoms section. The central Coulomb force on the outer-most $2 p$ shell electron of $F_{2}$ (electron 8) due to the nucleus and the inner seven electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{\text {ele }}=\frac{(Z-7) e^{2}}{4 \pi \varepsilon_{0} r_{8}^{2}} \mathbf{i}_{\mathrm{r}} \tag{13.711}
\end{equation*}
$$

for $r>r_{7}$. The $2 p$ shell possess an external electric field given by Eq. (10.92) for $r>r_{8}$. The energy is minimized with conservation of angular momentum. This condition is met when the diamagnetic force, $\mathbf{F}_{\text {diamagnetic }}$, of Eq. (10.82) due to the $p$ orbital contributions is the same as that of the reactant fluorine atoms given by Eq. (10.176) with $r_{8}$ replacing $r_{9}$ :

$$
\begin{align*}
\mathbf{F}_{\text {diamagnetic }} & =-\left(\frac{2}{3}\right) \frac{\hbar^{2}}{4 m_{e} r_{8}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \\
& =-\frac{2 \hbar^{2}}{12 m_{e} r_{8}^{2} r_{3}} \sqrt{\frac{3}{4}} \mathbf{i}_{\mathbf{r}} \tag{13.712}
\end{align*}
$$

Thus, $\mathbf{F}_{\text {diamagnetic }}$ due to the two filled $2 p$ orbitals per $F$ atom is twice that of $N_{2}$ given by Eq. (13.622) having one filled $2 p$ orbital per $N$ atom. $\mathbf{F}_{\operatorname{mag} 2}$ corresponding to the conserved spin and orbital angular momentum is also the same as that of the reactant fluorine atoms given by Eq. (10.177) and that of $N_{2}$ given by Eq. (13.623) where the outer radius of the $2 p$ shell of the
$F$ atoms of $F_{2}$ is $r_{8}$.

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 2}=\frac{1}{Z} \frac{3 \hbar^{2}}{m_{e} r_{8}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.713}
\end{equation*}
$$

The electric field external to the $2 p$ shell given by Eq. (10.92) for $r>r_{8}$ gives rise to a second diamagnetic force, $\mathbf{F}_{\text {diamagnetic 2 }}$, given by Eq. (10.93). $\mathbf{F}_{\text {diamagnetic } 2}$ due to the binding of the p-orbital electron having an electric field of +1 outside of its radius is :

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 2}=-\left[\frac{Z-8}{Z-7}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{m_{e} r_{8}^{4}} 10 \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.714}
\end{equation*}
$$

In addition, the contribution of a $2 p$ electron from each $F$ atom in the formation of the $\sigma$ MO gives rise to a paramagnetic force on the remaining paired $2 p$ electrons. The force $\mathbf{F}_{\text {mag }}$ is given by Eq. (13.625) wherein the radius is $r_{8}$ :

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 3}=\frac{\hbar^{2}}{4 m_{e} r_{8}^{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.715}
\end{equation*}
$$

The radius of the $2 p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.711)) and diamagnetic (Eqs. (13.712) and (13.714)), and paramagnetic (Eqs. (13.713) and (13.715)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{8}^{2}}{r_{8}}=\binom{\frac{(Z-7) e^{2}}{4 \pi \varepsilon_{0} r_{8}^{2}}-\frac{2 \hbar^{2}}{12 m_{e} r_{8}^{2} r_{3}} \sqrt{s(s+1)}+\frac{3 \hbar^{2}}{Z m_{e} r_{8}^{2} r_{3}} \sqrt{s(s+1)}}{-\left[\frac{Z-8}{Z-7}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{8}^{4} m_{e}} 10 \sqrt{s(s+1)}+\frac{\hbar^{2}}{4 m_{e} r_{8}^{3}} \sqrt{s(s+1)}} \tag{13.716}
\end{equation*}
$$

Substitution of $v_{8}=\frac{\hbar}{m_{e} r_{8}}$ (Eq. (1.35)) and $s=\frac{1}{2}$ into Eq. (13.716) gives:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} r_{8}^{3}}-\frac{\hbar^{2}}{4 m_{e} r_{8}^{3}} \sqrt{\frac{3}{4}}=\frac{(Z-7) e^{2}}{4 \pi \varepsilon_{0} r_{8}^{2}}-\frac{2 \hbar^{2}}{12 m_{e} r_{8}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{3 \hbar^{2}}{Z m_{e} r_{8}^{2} r_{3}} \sqrt{\frac{3}{4}}-\left[\frac{Z-8}{Z-7}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{8}^{4} m_{e}} 10 \sqrt{\frac{3}{4}} \tag{13.717}
\end{equation*}
$$

The quadratic equation corresponding to Eq. (13.717) is:

$$
\begin{equation*}
r_{8}^{2}-\frac{\frac{\hbar^{2}}{m_{e}}\left(1-\frac{\sqrt{3}}{8}\right)}{\left(\frac{(Z-7) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{2}{12}-\frac{3}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)^{2}} r_{8}-\frac{\frac{\hbar^{2}}{m_{e}}\left[\frac{Z-8}{Z-7}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3} 10 \sqrt{\frac{3}{4}}}{\left(\frac{(Z-7) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{2}{12}-\frac{3}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)}=0 \tag{13.718}
\end{equation*}
$$

The solution of Eq. (13.718) using the quadratic formula is:

$$
\begin{equation*}
r_{8}=\frac{a_{0}\left(1-\frac{\sqrt{3}}{8}\right)}{\left((Z-7)-\left(\frac{2}{12}-\frac{3}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)} \pm a_{0} \sqrt{\left(\frac{1-\frac{\sqrt{3}}{8}}{\left(\frac{\left.(Z-7)-\left(\frac{2}{12}-\frac{3}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}{\left(\frac{20 \sqrt{3}\left(\left[\frac{Z-8}{Z-7}\right]\left(1-\frac{\sqrt{2}}{2}\right)\right.}{\left((Z-7)-\left(\frac{2}{12}-\frac{3}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}\right.}\right)^{2}}\right.}, r_{3} \text { in units of } a_{0} \tag{13.719}
\end{equation*}
$$

The positive root of Eq. (13.719) must be taken in order that $r_{8}>0$. Substitution of $\frac{r_{3}}{a_{0}}=0.51382$ (Eq. (10.62) with $Z=9$ ) into Eq. (13.719) gives:

$$
\begin{equation*}
r_{8}=0.73318 a_{0} \tag{13.720}
\end{equation*}
$$

## ENERGIES OF THE $2 p$ SHELL OF THE FLUORINE ATOMS OF THE FLUORINE MOLECULE

The central forces on the $2 p$ shell of each $F$ are increased with the formation of the $\sigma$ MO, which reduces the shell's radius and increases its total energy. The Coulombic energy terms of the total energy of the two $F$ atoms at the new radius are calculated and added to the energy of the $\sigma$ MO to give the total energy of $F_{2}$. Then, the bond energy is determined from the total $F_{2}$ energy.

The radius $r_{9}$ of each fluorine atom before bonding is given by Eq. (10.182):

$$
\begin{equation*}
r_{9}=0.78069 a_{0} \tag{13.721}
\end{equation*}
$$

Using the initial radius $r_{9}$ of each $F$ atom and the final radius $r_{8}$ of the $F 2 p$ shell of $F_{2}$ (Eq. (13.720)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_{T}\left(F_{2}, 2 p\right)$ of the Coulombic energy change of the $F 2 p$ electrons of both atoms is determined using Eq. (10.102).

$$
\begin{align*}
E_{T}\left(F_{2}, 2 p\right) & =-2 \sum_{n=4}^{7} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{8}}-\frac{1}{r_{9}}\right)  \tag{13.722}\\
& =-2(13.60580 \mathrm{eV})(0.08301)(2+3+4+5)=-31.62353 \mathrm{eV}
\end{align*}
$$

## FORCE BALANCE OF THE $\sigma$ MO OF THE FLUORINE MOLECULE

The relativistic diamagnetic force $\mathbf{F}_{\text {diamagneticмо2 }}$ of $F_{2}$ is one half that of $N_{2}$ due to the two versus one filled $2 p$ orbitals per atom at the focus. The force balance equation for the $\sigma$-MO of the fluorine molecule is given by Eq. (11.200) and Eqs. (13.63313.634 ) with the correction of $1 / 2$ due the two $2 p$ orbitals per $F$ after Eqs. (10.2-10.11), $n_{e}=5$, and $|L|=\hbar$ :

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(\frac{5}{2}+\frac{1}{2 Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{13.723}\\
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D-\left(\frac{3}{2}+\frac{1}{2 Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{13.724}\\
& \left(\frac{7}{2}+\frac{1}{2 Z}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D  \tag{13.725}\\
& a=\left(\frac{7}{2}+\frac{1}{2 Z}\right) a_{0} \tag{13.726}
\end{align*}
$$

Substitution of $Z=9$ into Eq. (13.726) gives:

$$
\begin{equation*}
a=3.55556 a_{0}=1.88152 \times 10^{-10} \mathrm{~m} \tag{13.727}
\end{equation*}
$$

Substitution of Eq. (13.727) into Eq. (11.79) is:

$$
\begin{equation*}
c^{\prime}=1.33333 a_{0}=7.05569 \times 10^{-11} \mathrm{~m} \tag{13.728}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.728) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.66667 a_{0}=1.41114 \times 10^{-10} \mathrm{~m} \tag{13.729}
\end{equation*}
$$

The experimental bond distance is [28] :

$$
\begin{equation*}
2 c^{\prime}=1.41193 \times 10^{-10} \mathrm{~m} \tag{13.730}
\end{equation*}
$$

Substitution of Eqs. (13.727-13.728) into Eq. (11.80) is:

$$
\begin{equation*}
b=c=3.29609 a_{0}=1.74421 \times 10^{-10} \mathrm{~m} \tag{13.731}
\end{equation*}
$$

Substitution of Eqs. (13.727-13.728) into Eq. (11.67) is:

$$
\begin{equation*}
e=0.37500 \tag{13.732}
\end{equation*}
$$

Using the electron configuration of $F_{2}$ (Eq. (13.710)), the radii of the $F 1 s=0.11297 a_{0}$ (Eq. (10.51)), $F 2 s=0.51382 a_{0}$ (Eq. (10.62)), and $F 2 p=0.73318 a_{0}$ (Eq. (13.720)) shells and the parameters of the $\sigma \mathrm{MO}$ of $F_{2}$ given by Eqs. (13.3-13.4), (13.72713.728), and (13.731-13.732), the dimensional diagram and charge-density of the $F_{2} \mathrm{MO}$ are shown in Figures 13.18 and 13.19, respectively.

Figure 13.18. The cross section of the $F_{2}$ MO showing the axes, $\sigma$ MO ( $H_{2}$-type ellipsoidal MO), with the $F 1 s, 2 s$, and $2 p$ atomic orbitals (AOs). Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $r_{8}$ : radius of the $F 2 p$ shell having two paired electrons.

Figure 13.19. $F_{2} \mathrm{MO}$ comprising the $\sigma \mathrm{MO}\left(H_{2}\right.$-type MO) with $F$ atoms at the foci that have each donated an electron to the $\sigma$ MO and have smaller radii and higher binding energies as a consequence. (A) Color scale, translucent view of the charge-density of the $F_{2}$ MO. (B) Off-center cutaway view showing the complete inner most $F 1 s$ shell, and moving radially, the $F 2 s$ shell, the $F 2 p$ shell, and the $\sigma$ prolate spheroidal MO that have the $F$ atoms as the foci.

## SUM OF THE ENERGIES OF THE $\sigma$ MO AND THE AOs OF THE FLUORINE MOLECULE

The energies of the $F_{2} \sigma \mathrm{MO}$ are given by the substitution of the semiprincipal axes (Eqs. (13.683-13.684) and (13.687)) into the energy equations (Eqs. (11.207-11.212)) of $\mathrm{H}_{2}$ :

$$
\begin{align*}
& V_{e}=\frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-16.09139 \mathrm{eV}  \tag{13.733}\\
& V_{p}=\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=10.20435 \mathrm{eV}  \tag{13.734}\\
& T=\frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=2.26285 \mathrm{eV}  \tag{13.735}\\
& V_{m}=\frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-1.13143 \mathrm{eV}  \tag{13.736}\\
& E_{T}=V_{e}+T+V_{m}+V_{p} \tag{13.737}
\end{align*}
$$

Substitution of Eqs. (11.79) and (13.733-13.736) into Eq. (13.737) gives:

$$
\begin{align*}
E_{T}\left(F_{2}, \sigma\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right)  \tag{13.738}\\
& =-4.75562 \mathrm{eV}
\end{align*}
$$

where $E_{T}\left(F_{2}, \sigma\right)$ is the total energy of the $\sigma \mathrm{MO}$ of $F_{2}$. The sum, $E_{T}\left(F_{2}\right)$, of $E_{T}\left(F_{2}, 2 p\right)$, the $2 p \mathrm{AO}$ contribution given by Eq. (13.722), and $E_{T}\left(F_{2}, \sigma\right)$, the $\sigma$ MO contribution given by Eq. (13.738) is:

$$
\begin{align*}
E_{T}\left(F_{2}\right) & =E_{T}\left(F_{2}, 2 p\right)+E_{T}\left(F_{2}, \sigma\right)  \tag{13.739}\\
& =-31.62353 \mathrm{eV}-4.75562 \mathrm{eV}=-36.37915 \mathrm{eV}
\end{align*}
$$

## VIBRATION OF $F_{2}$

The vibrational energy levels of $F_{2}$ may be solved by determining the Morse potential curve from the energy relationships for the transition from two $F$ atoms whose parameters are given by Eqs. (10.174-10.183) to the two $F$ atoms whose parameter $r_{8}$ is given by Eq. (13.720) and the $\sigma \mathrm{MO}$ whose parameters are given by Eqs. (13.727-13.729) and (13.731-13.732). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K\&P) [15] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

## THE DOPPLER ENERGY TERMS OF THE FLUORINE MOLECULE

The equations of the radiation reaction force of fluorine are the same as those of $\mathrm{H}_{2}$ with the substitution of the fluorine parameters. Using Eqs. (11.231-11.233), the angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}=6.16629 \times 10^{15} \mathrm{rad} / \mathrm{s} \tag{13.740}
\end{equation*}
$$

where $a$ is given by Eq. (13.727). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 6.16629 \times 10^{15} \mathrm{rad} / \mathrm{s}=4.05876 \mathrm{eV} \tag{13.741}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(F_{2}\right)$ for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.741) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-36.37915 \mathrm{eV} \sqrt{\frac{2 e(4.05876 \mathrm{eV})}{m_{e} c^{2}}}=-0.14499 \mathrm{eV} \tag{13.742}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $F_{2} \mathrm{MO}$ due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.742) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy. Using the experimental $F_{2} \omega_{e}$ of $916.64 \mathrm{~cm}^{-1}(0.11365 \mathrm{eV})$ [28] for $\bar{E}_{\text {Kvib }}$ of the transition state, $\bar{E}_{\text {osc }}\left(F_{2}\right)$ is:

$$
\begin{align*}
& \bar{E}_{\text {osc }}\left(F_{2}\right)=\bar{E}_{D}+\bar{E}_{\text {Kvib }}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.743}\\
& \bar{E}_{\text {osc }}\left(F_{2}\right)=-0.14499 \mathrm{eV}+\frac{1}{2}(0.11365 \mathrm{eV})=-0.08817 \mathrm{eV} \tag{13.744}
\end{align*}
$$

## TOTAL AND BOND ENERGIES OF THE FLUORINE MOLECULE

$E_{T+o s c}\left(F_{2}\right)$, the total energy of $F_{2}$ including the Doppler term, is given by the sum of $E_{T}\left(F_{2}\right)$ (Eq. (13.739)) and $\bar{E}_{\text {osc }}\left(F_{2}\right)$ given by Eq. (13.744):

$$
\begin{align*}
E_{T+o s c}\left(F_{2}\right) & =V_{e}+T+V_{m}+V_{p}+E_{T}\left(F_{2}, 2 p\right)+\bar{E}_{\text {osc }}\left(F_{2}\right) \\
& =E_{T}\left(F_{2}, \sigma\right)+E_{T}\left(F_{2}, 2 p\right)+\bar{E}_{\text {osc }}\left(F_{2}\right)  \tag{13.745}\\
& =E_{T}\left(F_{2}\right)+\bar{E}_{\text {osc }}\left(F_{2}\right) \\
E_{T+\text { osc }}\left(F_{2}\right) & =\left\{\begin{array}{l}
\left(\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right)-2 \sum_{n=4}^{7} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{8}}-\frac{1}{r_{9}}\right)\right) \\
\left.1+\sqrt{\frac{e^{2}}{\frac{4 \pi \varepsilon_{0} a^{3}}{m_{e}}}}\right)+\frac{1}{m_{e} c^{2}} \hbar \sqrt{\frac{k}{\mu}}
\end{array}\right)  \tag{13.746}\\
& =-36.37915 \mathrm{eV}-0.14499 \mathrm{eV}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}
\end{align*}
$$

From Eqs. (13.743-13.746), the total energy of the $F_{2} \mathrm{MO}$ is:

$$
\begin{equation*}
E_{T+o s c}\left(F_{2}\right)=-36.37915 \mathrm{eV}+\bar{E}_{o s c}\left(F_{2}\right)=-36.37915 \mathrm{eV}-0.14499 \mathrm{eV}+\frac{1}{2}(0.11365 \mathrm{eV})=-36.46732 \mathrm{eV} \tag{13.747}
\end{equation*}
$$

where the experimental $\omega_{e}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The $F_{2}$ bond dissociation energy, $E_{D}\left(F_{2}\right)$, is given by the difference in the total energies of the two $F$ atoms and $E_{T+o s c}\left(F_{2}\right)$ :

$$
\begin{equation*}
E_{D}\left(F_{2}\right)=2 E(F)-E_{T+o s c}\left(F_{2}\right) \tag{13.748}
\end{equation*}
$$

where the energy of a fluorine atom is [6]:

$$
\begin{equation*}
E(F)=-17.42282 \mathrm{eV} \tag{13.749}
\end{equation*}
$$

Thus, the $F_{2}$ bond dissociation energy, $E_{D}\left(F_{2}\right)$, given by Eqs. (13.747-13.749) is:

$$
\begin{equation*}
E_{D}\left(F_{2}\right)=-2(17.42282 \mathrm{eV})-E_{T+o s c}\left(F_{2}\right)=-34.84564 \mathrm{eV}-(-36.46732 \mathrm{eV})=1.62168 \mathrm{eV} \tag{13.750}
\end{equation*}
$$

The experimental $F_{2}$ bond dissociation energy is [48]:

$$
\begin{equation*}
E_{D}\left(F_{2}\right)=1.606 \mathrm{eV} \tag{13.751}
\end{equation*}
$$

The results of the determination of bond parameters of $F_{2}$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## CHLORINE MOLECULE

The chlorine molecule can be formed by the reaction of two chlorine atoms:

$$
\begin{equation*}
\mathrm{Cl}+\mathrm{Cl} \rightarrow \mathrm{Cl}_{2} \tag{13.752}
\end{equation*}
$$

The chlorine molecule can be solved by using the hybridization approach used to solve the methane series $C H_{n=1,2,3,4}$. In the methane series, the $2 s$ and $2 p$ shells of carbon hybridize to form a single $2 s p^{3}$ shell to achieve an energy minimum, and in a likewise manner, the $3 s$ and $3 p$ shells of chlorine hybridize to form a single $3 s p^{3}$ shell which forms the bonding orbital of $C l_{2}$.

## FORCE BALANCE OF $\mathrm{Cl}_{2}$

$\mathrm{Cl}_{2}$ has two spin-paired electrons in a chemical bond between the chlorine atoms. The $\mathrm{Cl}_{2}$ molecular orbital (MO) is determined by considering properties of the binding atoms and the boundary constraints. The prolate spheroidal $\mathrm{H}_{2} \mathrm{MO}$ developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules section satisfies the boundary constraints; thus, each Cl atom could contribute a $3 p$ electron to form a $\sigma \mathrm{MO}\left(H_{2}\right.$-type ellipsoidal MO) as in the case of $N_{2}, O_{2}$, and $F_{2}$. However, such a bond is not possible with the outer Cl electrons in their ground state since the resulting $3 p$ shells of chlorine atoms would overlap which is not energetically stable. Thus, when bonding, the chlorine $3 s$ and $3 p$ shells hybridize to form a single $3 s p^{3}$ shell to achieve an energy minimum.

The Cl electron configuration given in the Seventeen-Electron Atoms section is $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{5}$, and the orbital arrangement is:

\[

\]

corresponding to the ground state ${ }^{2} P_{3 / 2}^{0}$. The radius $r_{17}$ of the $3 p$ shell given by Eq. (10.363) is:

$$
\begin{equation*}
r_{17}=1.05158 a_{0} \tag{13.754}
\end{equation*}
$$

The energy of the chlorine $3 p$ shell is the negative of the ionization energy of the chlorine atom given by Eq. (10.364). Experimentally, the energy is [6]:

$$
\begin{equation*}
E(3 p \text { shell })=-E(\text { ionization } ; C l)=-12.96764 \mathrm{eV} \tag{13.755}
\end{equation*}
$$

The $C l 3 s$ atomic orbital (AO) combines with the $C l 3 p$ AOs to form a single $3 s p^{3}$ hybridized orbital (HO) with the orbital arrangement.

\[

\]

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the seven electrons. Using only the largest-force terms of the outer most and next inner shell, the calculated energies for the chlorine atom and the ions: $\mathrm{Cl}, \mathrm{Cl}^{+}, \mathrm{Cl}^{2+}, \mathrm{Cl}^{3+}, C l^{4+}, C l^{5+}$ and $\mathrm{Cl}^{6+}$ are given in Eqs. (10.363-10.364), (10.353-10.354), (10.331-10.332), (10.309-10.310), (10.288-10.289), (10.255-10.256), and (10.235-10.236), respectively. The sum $E_{T}\left(C l, 3 s p^{3}\right)$ of the experimental energies of Cl and these ions is [6]:

$$
\begin{equation*}
E_{T}\left(C l, 3 s p^{3}\right)=\binom{12.96764 \mathrm{eV}+23.814 \mathrm{eV}+39.61 \mathrm{eV}+53.4652 \mathrm{eV}}{+67.8 \mathrm{eV}+97.03 \mathrm{eV}+114.1958 \mathrm{eV}}=408.88264 \mathrm{eV} \tag{13.757}
\end{equation*}
$$

The spin and orbital-angular-momentum interactions cancel such that the energy of the $E_{T}\left(C l, 3 s p^{3}\right)$ is purely Coulombic. By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 s p^{3}}$ of the $C l 3 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (10.102):

$$
\begin{equation*}
r_{3 s p^{3}}=\sum_{n=10}^{16} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 408.8826 \mathrm{eV})}=\frac{28 e^{2}}{8 \pi \varepsilon_{0}(e 408.8826 \mathrm{eV})}=0.93172 a_{0} \tag{13.758}
\end{equation*}
$$

where $Z=17$. Using Eqs. (10.102) and (13.758), the Coulombic energy $E_{\text {Coulomb }}\left(C l, 3 s p^{3}\right)$ of the outer electron of the $C l 3 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(C l, 3 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.93172 a_{0}}=-14.60295 \mathrm{eV} \tag{13.759}
\end{equation*}
$$

The calculated energy of the $C 2 s p^{3}$ shell of 14.63489 eV given by Eq. (13.428), and nitrogen's calculated energy of 14.61664 eV given by Eq. (10.143) is a close match with $E_{\text {Coulomb }}\left(C l, 3 s p^{3}\right)$.

The unpaired $C l 3 s p^{3}$ electrons from each of two chlorine atoms combine to form a molecular orbital. The nuclei of the $C l$ atoms are along the internuclear axis and serve as the foci. Due to symmetry, the other $C l$ electrons are equivalent to point charges at the origin. (See Eqs. (19-38) of Appendix II.) Thus, the energies in the Cl MO involve only the two $\mathrm{Cl} 3 \mathrm{sp}{ }^{3}$ electrons. The forces are determined by these energies.

As in the case of $\mathrm{H}_{2}$, the MO is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $C l 3 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C l 3 s p^{3}$ shell of each atom. Thus, the MO surface comprises a partial prolate spheroid in between the nuclei and is continuous with the $\mathrm{Cl} 3 \mathrm{sp}{ }^{3}$ shell at each Cl atom. The energy of the $\mathrm{H}_{2}$-type ellipsoidal MO is matched to that of the $\mathrm{Cl} 3 \mathrm{sp}{ }^{3}$ shell. As in the case with $\mathrm{OH}, \mathrm{NH}$, and CH (where the latter also demonstrates $s p^{3}$ hybridization) the linear combination of the $H_{2}$-type ellipsoidal MO with each $C l 3 s p^{3}$ HO must involve a $25 \%$ contribution from the $H_{2}$-type ellipsoidal MO to the $C l 3 s p^{3} \mathrm{HO}$ in order to match potential, kinetic, and orbital energy relationships. Thus, the $\mathrm{Cl}_{2} \mathrm{MO}$ must comprise two $\mathrm{Cl} 3 \mathrm{sp}{ }^{3} \mathrm{HOs}$ and $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO divided between the two Cl3sp ${ }^{3}$ HOs:

$$
\begin{equation*}
2 \mathrm{Cl}_{3} \mathrm{sp}^{3}+0.75 \mathrm{H}_{2} \mathrm{MO} \rightarrow \mathrm{Cl}_{2} \mathrm{MO} \tag{13.760}
\end{equation*}
$$

The force balance of the $\mathrm{Cl}_{2} \mathrm{MO}$ is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.760) and the energy matching condition between the $\mathrm{H}_{2}$-type-ellipsoidal-MO and $\mathrm{Cl} 3 \mathrm{sp} \mathrm{p}^{3}$ - HO components of the MO.

As in the case with OH (Eq. (13.57)), NH (Eq. (13.247)), and CH (Eq. (13.429)), the $\mathrm{H}_{2}$-type ellipsoidal MO comprises $75 \%$ of the $\mathrm{Cl}_{2} \mathrm{MO}$; so, the electron charge density in Eq. (11.65) is given by -0.75 e . Since the chlorine atoms of $\mathrm{Cl}_{2}$ are hybridized and the $k$ parameter is different from unity in order to meet the boundary constraints, both $k$ and $k^{\prime}$ must comprise the corresponding hybridization factors. (In contrast, the chlorine atom of a $\mathrm{C}-\mathrm{Cl}$ bond of an alkyl chloride is not hybridized, and only $k^{\prime}$ must comprise the corresponding hybridization factor.) The force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ in terms of the central force of the foci is given by Eq. (13.59), except that $k^{\prime}$ is divided by two since the $H_{2}$-type-ellipsoidal-MO is physically divided between two $C l 3 s p^{3}$ HOs. In addition, the energy matching at both $C l 3 s p^{3}$ HOs further requires that $k^{\prime}$ be corrected with the hybridization factor given by Eq. (13.762). Thus, $k^{\prime}$ of the $H_{2}$-type-ellipsoidal-MO component of the $\mathrm{Cl}_{2} \mathrm{MO}$ is:

$$
\begin{equation*}
k^{\prime}=C_{C 13 s p^{3} H O} \frac{(0.75)}{2} \frac{2 e^{2}}{4 \pi \varepsilon_{0}}=0.93172 \frac{(0.75)}{2} \frac{2 e^{2}}{4 \pi \varepsilon_{0}} \tag{13.761}
\end{equation*}
$$

The distance from the origin to each focus $c^{\prime}$ is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C l-C l$-bond $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of the $\mathrm{Cl}_{2} \mathrm{MO}$. Since the $\mathrm{Cl}_{2} \mathrm{MO}$ comprises a $\mathrm{H}_{2}$-type-ellipsoidal MO that transitions to the $\mathrm{Cl} 3 \mathrm{sp}{ }^{3}$ HOs at each end of the molecule, the energy $E\left(C l, 3 s p^{3}\right)$ in Eq. (13.759) adds to that of the $H_{2}$-type ellipsoidal MO to give the total energy of the $\mathrm{Cl}_{2} \mathrm{MO}$. From the energy equation and the relationship between the axes, the dimensions of the $\mathrm{Cl}_{2} \mathrm{MO}$ are solved.

The energy components of $V_{e}, V_{p}, T$, and $V_{m}$ are those of $H_{2}$ (Eqs. (11.207-11.211)) except that they are corrected for electron hybridization. Hybridization gives rise to the $C l 3 s p^{3}$ HO-shell Coulombic energy $E_{\text {Coulomb }}\left(C l, 3 s p^{3}\right)$ given by Eq. (13.759). To meet the equipotential condition of the union of the $H_{2}$-type-ellipsoidal-MO with each $C l 3 s p^{3} \mathrm{HO}$, the electron energies are normalized by the ratio of 14.60295 eV , the magnitude of $E_{\text {Coulomb }}\left(C l, 3 s p^{3}\right)$ given by Eq. (13.759), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). This normalizes the energies to match that of the Coulombic energy alone to meet the energy matching condition of the $C l_{2} \mathrm{MO}$ under the influence of the two $C l 3 s p^{3} \mathrm{HOs}$ bridged by the $H_{2}$-type-ellipsoidal MO. The hybridization energy factor $C_{C l 3 s p^{3} H O}$ is:

$$
\begin{align*}
C_{C l 3 s p^{3} H O} & =\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} r_{3 s p^{3}}}}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} 0.93172 a_{0}}}  \tag{13.762}\\
& =\frac{13.605804 \mathrm{eV}}{14.60295 \mathrm{eV}}=0.93172
\end{align*}
$$

The total energy $E_{T}\left(\mathrm{Cl}_{2}\right)$ of the $\mathrm{Cl}_{2} \mathrm{MO}$ is given by the sum of the energies of the orbitals, the $\mathrm{H}_{2}$-type ellipsoidal MO and the two $C l 3 s p^{3} \mathrm{HOs}$, that form the hybridized $\mathrm{Cl}_{2} \mathrm{MO} . E_{T}\left(\mathrm{Cl}_{2}\right)$ follows from Eq. (13.74) for OH , but the energy of the $\mathrm{Cl} 3 s p^{3}$ HO given by Eq. (13.759) is substituted for the energy of O and the $\mathrm{H}_{2}$-type-ellipsoidal-MO energies are those of $\mathrm{H}_{2}$ (Eqs. (11.207-11.212)) multiplied by the electron hybridization factor rather than by the factor of 0.75 :

$$
\begin{align*}
E_{T}\left(C l_{2}\right) & =E_{T}+E_{\text {Coulomb }}\left(C l, 3 s p^{3}\right) \\
& =-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.93172)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.60295 \mathrm{eV} \tag{13.763}
\end{align*}
$$

To match the boundary condition that the total energy of the entire the $H_{2}$-type ellipsoidal MO is given by Eqs. (11.212) and (13.75), $E_{T}\left(C l_{2}\right)$ given by Eq. (13.763) is set equal to Eq. (13.75):

$$
\begin{align*}
E_{T}\left(C l_{2}\right) & =-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.93172)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.60295 \mathrm{eV}  \tag{13.764}\\
& =-31.63537 \mathrm{eV}
\end{align*}
$$

From the energy relationship given by Eq. (13.764) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the $\mathrm{Cl}_{2} \mathrm{MO}$ can be solved.

Substitution of Eqs. (13.60) and (13.761) into Eq. (13.764) gives:

$$
\begin{equation*}
\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{4 a a_{0}}{3(0.93172)}}}\left[(0.93172)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{4 a a_{0}}{3(0.93172)}}}{a-\sqrt{\frac{4 a a_{0}}{3(0.93172)}}}-1\right]=e 17.03242 \tag{13.765}
\end{equation*}
$$

The most convenient way to solve Eq. (13.765) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is:

$$
\begin{equation*}
a=2.46500 a_{0}=1.30442 \times 10^{-10} \mathrm{~m} \tag{13.766}
\end{equation*}
$$

Substitution of Eq. (13.766) into Eq. (13.60) gives:

$$
\begin{equation*}
c^{\prime}=1.87817 a_{0}=9.93887 \times 10^{-11} \mathrm{~m} \tag{13.767}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.767) by two is:

$$
\begin{equation*}
2 c^{\prime}=3.75635 a_{0}=1.98777 \times 10^{-10} \mathrm{~m} \tag{13.768}
\end{equation*}
$$

The experimental bond distance is [28]:

$$
\begin{equation*}
2 c^{\prime}=1.988 \times 10^{-10} \mathrm{~m} \tag{13.769}
\end{equation*}
$$

Substitution of Eqs. (13.766-13.767) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=1.59646 a_{0}=8.44810 \times 10^{-11} \mathrm{~m} \tag{13.770}
\end{equation*}
$$

Substitution of Eqs. (13.766-13.767) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.76194 \tag{13.771}
\end{equation*}
$$

The Cl nuclei comprise the foci of the $\mathrm{H}_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C l 3 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{3 s p^{3}}=0.93172 a_{0}$ is the radius of the $C l 3 s p^{3}$ shell. Substitution of Eqs. (13.766-13.767) into Eq. (13.261) gives

$$
\begin{equation*}
\theta^{\prime}=81.72^{\circ} \tag{13.772}
\end{equation*}
$$

Then, the angle $\theta_{C 13 s p^{3} H O}$ the radial vector of the $C l 3 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C l 3 s p^{3} H O}=180^{\circ}-81.72^{\circ}=98.28^{\circ} \tag{13.773}
\end{equation*}
$$

as shown in Figure 13.20. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{3 s p^{3}} \sin \theta_{C 13 s p^{3} H O}=0.93172 a_{0} \sin \theta_{C l 3 s p^{3} H O}=b \sin \theta_{H_{2} M O} \tag{13.774}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{H_{2} M O}=\sin ^{-1} \frac{0.93172 a_{0} \sin \theta_{C 13 s p^{3} H O}}{b}=\sin ^{-1} \frac{0.93172 a_{0} \sin 98.28^{\circ}}{b} \tag{13.775}
\end{equation*}
$$

with the use of Eq. (13.773). Substitution of Eq. (13.770) into Eq. (13.775) gives:

$$
\begin{equation*}
\theta_{\mathrm{H}_{2} \mathrm{MO}}=35.28^{\circ} \tag{13.776}
\end{equation*}
$$

Then, the distance $d_{\mathrm{H}_{2} \mathrm{MO}}$ along the internuclear axis from the origin of $\mathrm{H}_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{\mathrm{H}_{2} \mathrm{MO}}=a \cos \theta_{\mathrm{H}_{2} \mathrm{MO}} \tag{13.777}
\end{equation*}
$$

Substitution of Eqs. (13.766) and (13.776) into Eq. (13.777) gives:

$$
\begin{equation*}
d_{H_{2} M O}=2.01235 a_{0}=1.06489 \times 10^{-10} \mathrm{~m} \tag{13.778}
\end{equation*}
$$

The distance $d_{C 13 s p^{3}{ }^{3} O}$ along the internuclear axis from the origin of each Cl atom to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C l 3 s p^{3} H O}=d_{H_{2} M O}-c^{\prime} \tag{13.779}
\end{equation*}
$$

Substitution of Eqs. (13.768) and (13.778) into Eq. (13.779) gives:

$$
\begin{equation*}
d_{C l 3 s p^{3} H O}=0.13417 a_{0}=7.10022 \times 10^{-12} \mathrm{~m} \tag{13.780}
\end{equation*}
$$

As shown in Eq. (13.760), a factor of 0.25 of the charge-density of the $H_{2}$-type ellipsoidal MO is distributed on each $C l 3 s p^{3}$ HO. Using the orbital composition of $C l_{2}$ (Eq. (13.760)), the radii of the $C l 1 s=0.05932 a_{0}$ (Eq. (10.51)), $C l 2 s=0.25344 a_{0}$ (Eq. (10.62)), $C l 2 p=0.31190 a_{0}$ (Eq. (10.212)), and $C l 3 s p^{3}=0.93172 a_{0}$ (Eq. (13.758)) shells, and the parameters of the $\mathrm{Cl}_{2} \mathrm{MO}$ given by Eqs. (13.3-13.4), (13.766-13.768), and (13.770-13.771), the dimensional diagram and charge-density of the $\mathrm{Cl}_{2} \mathrm{MO}$ comprising the linear combination of the $\mathrm{H}_{2}$-type ellipsoidal MO and two $\mathrm{Cl3sp}{ }^{3} \mathrm{HOs}$ according to Eq. (13.760) are shown in Figures 13.20 and 13.21, respectively.

Figure 13.20. The cross section of the $\mathrm{Cl}_{2} \mathrm{MO}$ showing the axes, angles, and point of intersection of the $H_{2}$-type ellipsoidal MO with the two $C l 3 s p^{3}$ HOs. The continuation of the $H_{2}$-type-ellipsoidal-MO basis element beyond the intersection point with each $C l 3 s p^{3}$ shell is shown as dashed since it only serves to solve the energy match with each $C l 3 s p^{3}$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of the intersection points. The actual charge density is shown by the solid lines. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $d_{1}: d_{H_{2} M O}$, $\theta_{1}: \theta_{C l 3 s p^{3} H O}, d_{2}: d_{C l 1 s p^{3} H O}$, and $R: r_{3 s p^{3}}$.

Figure 13.21. $C l_{2} \mathrm{MO}$ comprising the superposition of the $H_{2}$-type ellipsoidal MO and the two $C l 3 s p^{3} \mathrm{HOs}$, each with a relative charge-density of 0.75 to 1.25 divided between the former and the latter; otherwise, the $C l 3 s p^{3} \mathrm{HO}$ is unchanged. (A) Side-on, color scale, translucent view of the charge-density of the $\mathrm{Cl}_{2} \mathrm{MO}$. The ellipsoidal surface of the $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the $C l 3 s p^{3} \mathrm{HO}$, the $C l 3 s p^{3} \mathrm{HO}$, and the $C l 1 s, C l 2 s$, and $C l 2 p$ shells of each $C l$ atom are shown. (B) Cut-away view showing the inner most $C l 1 s$ shell, and moving radially, the $C l 2 s, C l 2 p$, and $C l 3 s p^{3}$ shells, and the $H_{2}$-type ellipsoidal MO that transitions to the $C l 3 s p^{3}$ HOs.

## ENERGIES OF $\mathrm{Cl}_{2}$

The energies of $\mathrm{Cl}_{2}$ are given by the substitution of the semiprincipal axes (Eqs. (13.766-13.767) and (13.770)) into the energy equations, (Eq. (13.763) and Eqs. (11.207-11.211) of $\mathrm{H}_{2}$ ) that are corrected for electron hybridization using Eq. (13.762).

$$
\begin{align*}
& V_{e}=(0.93172) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-27.02007 \mathrm{eV}  \tag{13.781}\\
& V_{p}=\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=7.24416 \mathrm{eV}  \tag{13.782}\\
& T=(0.93172) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=5.48074 \mathrm{eV}  \tag{13.783}\\
& V_{m}=(0.93172) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-2.74037 \mathrm{eV}  \tag{13.784}\\
& E_{T}\left({ }^{35} \mathrm{Cl} l_{2}\right)=-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.93172)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.60295 \mathrm{eV}=-31.63537 \mathrm{eV} \tag{13.785}
\end{align*}
$$

where $E_{T}\left(C l_{2}\right)$ is given by Eq. (13.763) which is reiteratively matched to Eq. (13.75) within five-significant-figure round-off error.

## VIBRATION AND ROTATION OF $\mathrm{Cl}_{2}$

In $\mathrm{Cl}_{2}$, the division of the $\mathrm{H}_{2}$-type ellipsoidal MO between the two $C l 3 s p^{3} \mathrm{HOs}$ and the hybridization must be considered in determining the vibrational parameters. One approach is to use Eq. (13.761) for the force constant and $r_{3 s p^{3}}$ given by Eq. (13.758) for the distance parameter of the central force in Eq. (11.213) since the $H_{2}$-type ellipsoidal MO is energy matched to the $C l 3 s p^{3}$ HOs. With the substitution of the $\mathrm{Cl}_{2}$ parameters in Eqs. (11.213-11.217), the angular frequency of the oscillation is:

$$
\begin{align*}
\omega & =\sqrt{\frac{0.93172 \frac{(0.75)}{2} \frac{e^{2}}{8 \pi \varepsilon_{0}\left(r_{3 s p^{3}}\right)^{3}}-\frac{e^{2}}{8 \pi \varepsilon_{0}\left(r_{3 s p^{3}}+c^{\prime}\right)^{3}}}{\mu}} \\
& =\sqrt{\frac{0.93172 \frac{(0.75)}{2} \frac{e^{2}}{\frac{8 \pi \varepsilon_{0}(0.93172)^{3}}{35}-\frac{e^{2}}{8 \pi \varepsilon_{0}\left(0.93172 a_{0}+1.87817 a_{0}\right)^{3}}}}{\frac{35}{2} m_{p}}}=1.01438 \times 10^{14} \mathrm{rad} / \mathrm{s} \tag{13.786}
\end{align*}
$$

where $c^{\prime}$ is given by Eq. (13.767), and the reduced mass of ${ }^{35} \mathrm{Cl}_{2}$ is given by:

$$
\begin{equation*}
\mu_{35 C_{2}}=\frac{m_{1} m_{2}}{m_{1}+m_{2}}=\frac{(35)(35)}{35+35} m_{p} \tag{13.787}
\end{equation*}
$$

where $m_{p}$ is the proton mass. Thus, during bond formation, the perturbation of the orbit determined by an inverse-squared force results in simple harmonic oscillatory motion of the orbit, and the corresponding frequency, $\omega(0)$, for ${ }^{35} \mathrm{Cl}_{2}$ given by Eqs. (11.136), (11.148), and (13.786) is:

$$
\begin{equation*}
\omega(0)=\sqrt{\frac{k(0)}{\mu}}=\sqrt{\frac{301.19 \mathrm{Nm}^{-1}}{\mu}}=1.01438 \times 10^{14} \text { radians } / \mathrm{s} \tag{13.788}
\end{equation*}
$$

where the reduced nuclear mass of ${ }^{35} \mathrm{Cl}_{2}$ is given by Eq. (13.787) and the spring constant, $k(0)$, given by Eqs. (11.136) and (13.786) is:

$$
\begin{equation*}
k(0)=301.19 \mathrm{Nm}^{-1} \tag{13.789}
\end{equation*}
$$

The ${ }^{35} \mathrm{Cl}_{2}$ transition-state vibrational energy, $E_{v i b}(0)$ or $\omega_{e}$, given by Planck's equation (Eq. (11.127)) is:

$$
\begin{equation*}
E_{v i b}(0)=\omega_{e}=\hbar \omega=\hbar 1.01438 \times 10^{14} \mathrm{rad} / \mathrm{s}=0.06677 \mathrm{eV}=538.52 \mathrm{~cm}^{-1} \tag{13.790}
\end{equation*}
$$

$\omega_{e}$, from the experimental curve fit of the vibrational energies of ${ }^{35} \mathrm{Cl}_{2}$ is [28] :

$$
\begin{equation*}
\omega_{e}=559.7 \mathrm{~cm}^{-1} \tag{13.791}
\end{equation*}
$$

Using Eqs. (13.112-13.118) with $E_{v i b}(0)$ given by Eq. (13.790) and $D_{0}$ given by Eq. (13.807), the ${ }^{35} \mathrm{Cl}_{2} \quad v=1 \rightarrow v=0$ vibrational energy, $E_{v i b}(1)$ is:

$$
\begin{equation*}
E_{v i b}(1)=0.0659 \mathrm{eV} \quad\left(531.70 \mathrm{~cm}^{-1}\right) \tag{13.792}
\end{equation*}
$$

The experimental vibrational energy of ${ }^{35} \mathrm{Cl}_{2}$ using $\omega_{e}$ and $\omega_{e} x_{e}$ [28] according to K\&P [15] is:

$$
\begin{equation*}
E_{v i b}(1)=0.0664 \mathrm{eV} \quad\left(535.55 \mathrm{~cm}^{-1}\right) \tag{13.793}
\end{equation*}
$$

Using Eq. (13.113) with $E_{v i b}(1)$ given by Eq. (13.792) and $D_{0}$ given by Eq. (13.807), the anharmonic perturbation term, $\omega_{0} x_{0}$, of ${ }^{35} \mathrm{Cl}_{2}$ is:

$$
\begin{equation*}
\omega_{0} x_{0}=3.41 \mathrm{~cm}^{-1} \tag{13.794}
\end{equation*}
$$

The experimental anharmonic perturbation term, $\omega_{0} x_{0}$, of ${ }^{35} \mathrm{Cl}_{2}$ [28] is:

$$
\begin{equation*}
\omega_{0} x_{0}=2.68 \mathrm{~cm}^{-1} \tag{13.795}
\end{equation*}
$$

The vibrational energies of successive states are given by Eqs. (13.790), (13.112), and (13.794).
Using Eqs. (13.133-13.134) and the internuclear distance, $r=2 c^{\prime}$, and reduced mass of ${ }^{35} \mathrm{Cl}_{2}$ given by Eqs. (13.768) and (13.787), respectively, the corresponding $B_{e}$ is:

$$
\begin{equation*}
B_{e}=0.2420 \mathrm{~cm}^{-1} \tag{13.796}
\end{equation*}
$$

The experimental $B_{e}$ rotational parameter of ${ }^{35} \mathrm{Cl}_{2}$ is [28]:

$$
\begin{equation*}
B_{e}=0.2440 \mathrm{~cm}^{-1} \tag{13.797}
\end{equation*}
$$

## THE DOPPLER ENERGY TERMS OF $\mathrm{Cl}_{2}$

The equations of the radiation reaction force of the symmetrical $C l_{2} \mathrm{MO}$ are the given by Eqs. (11.231-11.233) with the substitution of the $\mathrm{Cl}_{2}$ parameters and the substitution of the force factor of Eq. (13.761). The angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{0.93172 \frac{(0.75)}{2} \frac{e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}=6.31418 \times 10^{15} \mathrm{rad} / \mathrm{s} \tag{13.798}
\end{equation*}
$$

where $a$ is given by Eq. (13.766). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 1.6 .31418 \times 10^{15} \mathrm{rad} / \mathrm{s}=4.15610 \mathrm{eV} \tag{13.799}
\end{equation*}
$$

In Eq. (11.181), substitution of the total energy of $C l_{2}, E_{T}\left(C l_{2}\right)$, (Eq. (13.764)) for $E_{h \nu}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.799) for $\bar{E}_{K}$ gives the Doppler energy of the electrons for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h v} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-31.63537 \mathrm{eV} \sqrt{\frac{2 e(4.15610 \mathrm{eV})}{m_{e} c^{2}}}=-0.12759 \mathrm{eV} \tag{13.800}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of $\mathrm{Cl}_{2}$ due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.800) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of $\mathrm{Cl}_{2}$. Using the experimental ${ }^{35} \mathrm{Cl}_{2} \omega_{e}$ of $559.7 \mathrm{~cm}^{-1}(0.06939 \mathrm{eV})$ [28] for $\bar{E}_{\text {Kvib }}$ of the transition state, $\bar{E}_{\text {osc }}\left({ }^{35} \mathrm{Cl}_{2}\right)$ is:

$$
\begin{align*}
& \bar{E}_{\text {osc }}\left({ }^{35} \mathrm{Cl}_{2}\right)=\bar{E}_{D}+\bar{E}_{\text {Kvib }}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.801}\\
& \bar{E}_{\text {osc }}\left({ }^{35} \mathrm{Cl}_{2}\right)=-0.12759 \mathrm{eV}+\frac{1}{2}(0.06939 \mathrm{eV})=-0.09289 \mathrm{eV} \tag{13.802}
\end{align*}
$$

## TOTAL AND BOND ENERGIES OF $\mathrm{Cl}_{2}$

$E_{T+o s c}\left({ }^{35} \mathrm{Cl}_{2}\right)$, the total energy of the ${ }^{35} \mathrm{Cl}_{2}$ radical including the Doppler term, is given by the sum of $E_{T}\left(\mathrm{Cl}_{2}\right)$ (Eq. (13.764)) and $\bar{E}_{\text {osc }}\left({ }^{35} \mathrm{Cl}_{2}\right)$ given by Eq. (13.802).

$$
\begin{align*}
E_{T+o s c}\left({ }^{35} \mathrm{Cl}_{2}\right) & =V_{e}+T+V_{m}+V_{p}+E_{\text {Coulomb }}\left(C l, 3 s p^{3}\right)+\bar{E}_{\text {osc }}\left({ }^{35} \mathrm{Cl}_{2}\right)=E_{T}\left(\mathrm{Cl}_{2}\right)+\bar{E}_{\text {osc }}\left({ }^{35} \mathrm{Cl}_{2}\right)  \tag{13.803}\\
E_{T+o s c}\left({ }^{35} \mathrm{Cl}_{2}\right) & =\left\{\left(\begin{array}{l}
\left(\frac{-e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.93172)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-14.60295 \mathrm{eV}\right) \\
\left.1+\sqrt{\frac{0 \hbar \sqrt{\frac{0.93172 \frac{(0.75)}{2} \frac{e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}}{m_{e} c^{2}}}\right)+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}
\end{array}\right\}\right.  \tag{13.804}\\
& =-31.63537 \mathrm{eV}-0.12759 \mathrm{eV}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}
\end{align*}
$$

From Eqs. (13.801-13.804), the total energy of ${ }^{35} \mathrm{Cl}_{2}$ is:

$$
\begin{align*}
E_{T+\text { osc }}\left({ }^{35} \mathrm{Cl}_{2}\right) & =-31.63537 \mathrm{eV}+\bar{E}_{\text {osc }}\left({ }^{35} \mathrm{Cl}_{2}\right) \\
& =-31.63537 \mathrm{eV}-0.12759 \mathrm{eV}+\frac{1}{2}(0.06939 \mathrm{eV})=-31.72826 \mathrm{eV} \tag{13.805}
\end{align*}
$$

where the experimental $\omega_{e}$ (Eq. (13.791)) was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The $C l_{2}$ bond dissociation energy, $E_{D}\left({ }^{35} \mathrm{Cl}_{2}\right)$, is given by the difference between the total energies of the two $C l 3 s p^{3}$ HOs and $E_{T+\text { osc }}\left({ }^{35} \mathrm{Cl}_{2}\right)$ :

$$
\begin{equation*}
E_{D}\left({ }^{35} l_{2}\right)=2 E_{\text {Coulomb }}\left(C l, 3 s p^{3}\right)-E_{T+o s c}\left({ }^{35} C l_{2}\right) \tag{13.806}
\end{equation*}
$$

$E_{\text {Coulomb }}\left(\mathrm{Cl}, 3 \mathrm{sp}{ }^{3}\right)$ is given by Eq. (13.759); thus, the ${ }^{35} \mathrm{Cl}_{2}$ bond dissociation energy, $E_{D}\left({ }^{35} \mathrm{Cl} 2\right)$, given by Eqs. (13.759) and (13.805-13.806) is

$$
\begin{equation*}
E_{D}\left({ }^{35} \mathrm{Cl}_{2}\right)=-2(14.60295 \mathrm{eV})-E_{T+o s c}\left({ }^{35} \mathrm{Cl}_{2}\right)=-29.20590 \mathrm{eV}-(-31.72826 \mathrm{eV})=2.52236 \mathrm{eV} \tag{13.807}
\end{equation*}
$$

The experimental ${ }^{35} \mathrm{Cl}_{2}$ bond dissociation energy is [49]:

$$
\begin{equation*}
E_{D}\left({ }^{35} \mathrm{Cl}_{2}\right)=2.51412 \mathrm{eV} \tag{13.808}
\end{equation*}
$$

The results of the determination of bond parameters of $\mathrm{Cl}_{2}$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## CARBON NITRIDE RADICAL

The carbon nitride radical can be formed by the reaction of carbon and nitrogen atoms:

$$
\begin{equation*}
C+N \rightarrow C N \tag{13.809}
\end{equation*}
$$

The bond in carbon nitride radical comprises a $H_{2}$-type molecular orbital (MO) with two paired electrons. The force balance equations and radii, $r_{6}$ and $r_{7}$, of the $2 p$ shell of $C$ and $N$ are derived in the Six-Electron Atoms section and Seven-Electron Atoms section, respectively. With the formation of the $H_{2}$-type MO by the contribution of a $2 p$ electron from each of the $C$ and $N$ atoms, a diamagnetic force arises between the remaining $2 p$ electrons of each atom and the $H_{2}$-type MO. This force from each atom causes the $H_{2}$-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the integer increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining $2 p$ electrons of each atom decrease the radii of the corresponding shells such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of $C N$ is $C 1 s^{2} N 1 s^{2} C 2 s^{2} N 2 s^{2} C 2 p^{1} N 2 p^{2} \sigma_{C, N}^{2}$ where $\sigma$ designates the $H_{2}$-type MO , and the orbital arrangement is:

The carbon nitride radical is predicted to be weakly paramagnetic.

## FORCE BALANCE OF THE $2 p$ SHELL OF THE CARBON ATOM OF THE CARBON NITRIDE RADICAL

For the $C$ atom, force balance for the outermost $2 p$ electron of $C N$ (electron 5) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 5 and the $2 s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Six-Electron Atoms section. The central Coulomb force on the outer-most $2 p$ shell electron of $C N$ (electron 5) due to the nucleus and the inner four electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{e l e}=\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0} r_{5}^{2}} \mathbf{i}_{\mathbf{r}} \tag{13.811}
\end{equation*}
$$

for $r>r_{4}$. The $2 p$ shell possess an external electric field given by Eq. (10.92) for $r>r_{5}$.
The single unpaired carbon $2 p$ electron gives rise to a diamagnetic force on the $\sigma-\mathrm{MO}$ as given by Eqs. (13.83513.839). The corresponding Newtonian reaction force cancels $\mathbf{F}_{\text {diamagnetic }}$, of Eq. (10.82). The energy is minimized with conservation of angular momentum. This condition is met when:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic }}=0 \tag{13.812}
\end{equation*}
$$

And, $\mathbf{F}_{\text {mag } 2}$ corresponding to the maximum orbital angular momentum of the three $2 p$ orbitals given by Eq. (10.89) is:

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 2}=\frac{1}{Z} \frac{3 \hbar^{2}}{m_{e} r_{5}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathrm{r}} \tag{13.813}
\end{equation*}
$$

The electric field external to the $2 p$ shell given by Eq. (10.92) for $r>r_{5}$ gives rise to a second diamagnetic force, $\mathbf{F}_{\text {diamagnetic 2 }}$, given by Eq. (10.93). $\mathbf{F}_{\text {diamagnetic } 2}$ due to the binding of the p-orbital electron having an electric field of +1 outside of its radius is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 2}=-\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{m_{e} r_{5}^{4}} 10 \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.814}
\end{equation*}
$$

The radius of the $2 p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.811)) and diamagnetic (Eqs. (13.812) and (13.814)), and paramagnetic (Eq. (13.813)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{5}^{2}}{r_{5}}=\binom{\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0} r_{5}^{2}}+\frac{3 \hbar^{2}}{Z m_{e} r_{5}^{2} r_{3}} \sqrt{s(s+1)}}{-\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{5}^{4} m_{e}} 10 \sqrt{s(s+1)}} \tag{13.815}
\end{equation*}
$$

Substitution of $v_{5}=\frac{\hbar}{m_{e} r_{5}}$ (Eq. (1.35)) and $s=\frac{1}{2}$ into Eq. (13.815) gives:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} r_{5}^{3}}=\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0} r_{5}^{2}}+\frac{3 \hbar^{2}}{Z m_{e} r_{5}^{2} r_{3}} \sqrt{\frac{3}{4}}-\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{5}^{4} m_{e}} 10 \sqrt{\frac{3}{4}} \tag{13.816}
\end{equation*}
$$

The quadratic equation corresponding to Eq. (13.816) is:

$$
\begin{equation*}
r_{5}^{2}-\frac{\frac{\hbar^{2}}{m_{e}}}{\left(\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0}}+\frac{3 \hbar^{2}}{Z m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)^{r}} r_{5}-\frac{\frac{\hbar^{2}}{m_{e}}\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3} 10 \sqrt{\frac{3}{4}}}{\left(\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0}}+\frac{3 \hbar^{2}}{Z m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)}=0 \tag{13.817}
\end{equation*}
$$

The solution of Eq. (13.817) using the quadratic formula is:

$$
r_{5}=\frac{a_{0}}{\left(\frac{1}{\left((Z-4)+\frac{3 \sqrt{3}}{Z 2 r_{3}}\right)} \pm a_{0} \sqrt{\left(\frac{\left.(Z-4)+\frac{3 \sqrt{3}}{Z 2 r_{3}}\right)}{}\right)^{2}}\right.} \begin{align*}
& \frac{20 \sqrt{3}\left(\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3}\right)}{\left((Z-4)+\frac{3 \sqrt{3}}{Z 2 r_{3}}\right)} \tag{13.818}
\end{align*}, r_{3} \text { in units of } a_{0}
$$

The positive root of Eq. (13.818) must be taken in order that $r_{5}>0$. Substitution of $\frac{r_{3}}{a_{0}}=0.84317$ (Eq. (10.62) with $Z=6$ ) into Eq. (13.818) gives:

$$
\begin{equation*}
r_{5}=0.88084 a_{0} \tag{13.819}
\end{equation*}
$$

## FORCE BALANCE OF THE $2 p$ SHELL OF THE NITROGEN ATOM OF THE CARBON NITRIDE RADICAL

For the $N$ atom, force balance for the outermost $2 p$ electron of $C N$ (electron 6 ) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 6 and the other $2 p$-shell as well as the $2 s$ shell electrons due to spin and orbital angular momentum. The forces used are derived in the Seven-Electron Atoms section. The central Coulomb force on the outer-most $2 p$ shell electron of $C N$ (electron 6) due to the nucleus and the inner five electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{\text {ele }}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}} \mathbf{i}_{\mathbf{r}} \tag{13.820}
\end{equation*}
$$

for $r>r_{5}$. The $2 p$ shell possess an external electric field given by Eq. (10.92) for $r>r_{6}$.
The forces to determine the radius of the $N 2 p$ shell of $N$ in $C N$ are the same as those of $N$ in $N_{2}$ except that in $C N$ there is a contribution from the Newtonian reaction force that arises from the single unpaired carbon $2 p$ electron. The energy is minimized with conservation of angular momentum. This condition is met when $\mathbf{F}_{\text {diamagnetic }}$ of $N$ in $C N$ is canceled by the $\sigma$ MO -reaction force. Eq. (13.622) becomes:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic }}=0 \tag{13.821}
\end{equation*}
$$

And, $\mathbf{F}_{\text {mag } 2}$ corresponding to the conserved orbital angular momentum of the three orbitals given by Eq. (10.89) is:

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 2}=\frac{1}{Z} \frac{3 \hbar^{2}}{m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.822}
\end{equation*}
$$

The electric field external to the $2 p$ shell given by Eq. (10.92) for $r>r_{6}$ gives rise to a second diamagnetic force, $\mathbf{F}_{\text {diamagnetic 2 }}$, given by Eq. (10.93). $\mathbf{F}_{\text {diamagnetic } 2}$ due to the binding of the p-orbital electron having an electric field of +1 outside of its radius is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 2}=-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{m_{e} r_{6}^{4}} 10 \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.823}
\end{equation*}
$$

The $N$ forces $\mathbf{F}_{\text {ele }}, \mathbf{F}_{\text {mag 2 }}, \mathbf{F}_{\text {diamagnetic 2 }}$, and $\mathbf{F}_{\text {mag } 3}$ of $C N$ are the same as those of $N_{2}$ given by Eqs. (13.621) and (13.623-13.624), respectively. In both cases, the contribution of a $2 p$ electron from the $N$ atom in the formation of the $\sigma$ MO gives rise to a paramagnetic force on the remaining two $2 p$ electrons that pair. Thus, the force, $\mathbf{F}_{\operatorname{mag} 3}$ of $C N$, given by Eq. (13.625) is:

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 3}=\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.824}
\end{equation*}
$$

The radius of the $2 p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.820)) and diamagnetic (Eqs. (13.821) and (13.823)), and paramagnetic (Eqs. (13.822) and (13.824)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{6}^{2}}{r_{6}}=\binom{\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}}+\frac{3 \hbar^{2}}{Z m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)}}{-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{6}^{4} m_{e}} 10 \sqrt{s(s+1)}+\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{s(s+1)}} \tag{13.825}
\end{equation*}
$$

Substitution of $v_{6}=\frac{\hbar}{m_{e} r_{6}}$ (Eq. (1.35)) and $s=\frac{1}{2}$ into Eq. (13.626) gives:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} r_{6}^{3}}-\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{\frac{3}{4}}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}}+\frac{3 \hbar^{2}}{Z m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}}-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{6}^{4} m_{e}} 10 \sqrt{\frac{3}{4}} \tag{13.826}
\end{equation*}
$$

The quadratic equation corresponding to Eq. (13.826) is

$$
\begin{equation*}
r_{6}^{2}-\frac{\frac{\hbar^{2}}{m_{e}}\left(1-\frac{\sqrt{3}}{8}\right)}{\left(\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0}}+\frac{3 \hbar^{2}}{Z m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)^{2}} r_{6}-\frac{\frac{\hbar^{2}}{m_{e}}\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3} 10 \sqrt{\frac{3}{4}}}{\left(\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0}}+\frac{3 \hbar^{2}}{Z m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)}=0 \tag{13.827}
\end{equation*}
$$

The solution of Eq. (13.827) using the quadratic formula is:

$$
r_{6}=\frac{a_{0}\left(1-\frac{\sqrt{3}}{8}\right)}{\left((Z-5)+\frac{3 \sqrt{3}}{Z 2 r_{3}}\right)} \pm a_{0} \sqrt{\left(\frac{1-\frac{\sqrt{3}}{8}}{\left(\frac{\left.(Z-5)+\frac{3 \sqrt{3}}{Z 2 r_{3}}\right)}{\left(\frac{20 \sqrt{3}\left(\left[\frac{Z-6}{Z-5}\right)\left(1-\frac{\sqrt{2}}{2}\right) r_{3}\right)}{\left((Z-5)+\frac{3 \sqrt{3}}{Z 2 r_{3}}\right)}\right.}\right)^{2}}\right.} \begin{align*}
& 2 \tag{13.828}
\end{align*} r_{3} \text { in units of } a_{0}
$$

The positive root of Eq. (13.828) must be taken in order that $r_{6}>0$. Substitution of $\frac{r_{3}}{a_{0}}=0.69385$ (Eq. (10.62) with $Z=7$ ) into Eq. (13.828) gives:

$$
\begin{equation*}
r_{6}=0.76366 a_{0} \tag{13.829}
\end{equation*}
$$

## ENERGIES OF THE $2 p$ SHELLS OF THE CARBON AND NITROGEN ATOMS OF THE CARBON NITRIDE RADICAL

The central forces on the $2 p$ shell of the $C$ and $N$ atoms are increased with the formation of the $\sigma$ MO which reduces each shell's radius and increases its total energy. The Coulombic energy terms of the total energy of the $C$ and $N$ atoms at the new radii are calculated and added to the energy of the $\sigma$ MO to give the total energy of $C N$. Then, the bond energy is determined from the total $C N$ energy.

The radius $r_{6}$ of the carbon atom before bonding is given by Eq. (10.122):

$$
\begin{equation*}
r_{6}=1.20654 a_{0} \tag{13.830}
\end{equation*}
$$

Using the initial radius $r_{6}$ of the $C$ atom and the final radius $r_{5}$ of the $C 2 p$ shell of $C N$ (Eq. (13.819)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_{T}(C N, C 2 p)$ of the Coulombic energy change of the $C 2 p$ electron is determined using Eq. (10.102):

$$
\begin{equation*}
E_{T}(C N, C 2 p)=-\sum_{n=4}^{4} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{5}}-\frac{1}{r_{6}}\right)=-(13.60580 \mathrm{eV})(0.30647)(2)=-8.33948 \mathrm{eV} \tag{13.831}
\end{equation*}
$$

The radius $r_{7}$ of the nitrogen atom before bonding is given by Eq. (10.142).

$$
\begin{equation*}
r_{7}=0.93084 a_{0} \tag{13.832}
\end{equation*}
$$

Using the initial radius $r_{7}$ of the $N$ atom and the final radius $r_{6}$ of the $N 2 p$ shell of $C N$ (Eq. (13.829)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_{T}(C N, N 2 p)$ of the Coulombic energy change of the $N 2 p$ electron is determined using Eq. (10.102):

$$
\begin{equation*}
E_{T}(C N, N 2 p)=-\sum_{n=4}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{6}}-\frac{1}{r_{7}}\right)=-(13.60580 \mathrm{eV})(0.23518)(2+3)=-15.99929 \mathrm{eV} \tag{13.833}
\end{equation*}
$$

## FORCE BALANCE OF THE $\sigma$ MO OF THE CARBON NITRIDE RADICAL

The diamagnetic force $\mathbf{F}_{\text {diamagneticMo1 }}$ for the $\sigma$-MO of the $C N$ molecule due to the two paired electrons in the $N 2 p$ shell given by Eq. (13.633) with $n_{e}=2$ is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO1 }}=\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{13.834}
\end{equation*}
$$

The force $\mathbf{F}_{\text {diamagneticMO2 }}$ is given by Eq. (13.634) except that the force is summed over the individual diamagnetic-force terms due to each component of angular momentum $\left|L_{i}\right|$ acting on the electrons of the $\sigma$-MO from each atom having a nucleus of charge $Z_{j}$ at one of the foci of the $\sigma-\mathrm{MO}$ :

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO2 } 2}=\sum_{i, j} \frac{\left|L_{i}\right| \hbar}{Z_{j} 2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{13.835}
\end{equation*}
$$

Using Eqs. (11.200), (13.633-13.634), and (13.834-13.835), the force balance for the $\sigma$-MO of the carbon nitride radical comprising carbon with charge $Z_{1}=6$ and $\left|L_{1}\right|=\hbar$ and $\left|L_{2}\right|=\sqrt{\frac{3}{4}} \hbar$ and nitrogen with $Z_{2}=7$ and $\left|L_{3}\right|=\hbar$ is:

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(1+\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{1}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{13.836}\\
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D-\left(\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{1}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{13.837}\\
& \left(2+\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{1}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D  \tag{13.838}\\
& a=\left(2+\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{1}{Z_{2}}\right) a_{0} \tag{13.839}
\end{align*}
$$

Substitution of $Z_{1}=6$ and $Z_{2}=7$ into Eq. (13.839) gives:

$$
\begin{equation*}
a=2.45386 a_{0}=1.29853 \times 10^{-10} \mathrm{~m} \tag{13.840}
\end{equation*}
$$

Substitution of Eq. (13.840) into Eq. (11.79) is:

$$
\begin{equation*}
c^{\prime}=1.10767 a_{0}=5.86153 \times 10^{-11} \mathrm{~m} \tag{13.841}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.841) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.21534 a_{0}=1.17231 \times 10^{-10} \mathrm{~m} \tag{13.842}
\end{equation*}
$$

The experimental bond distance from Ref. [28] is:

$$
\begin{equation*}
2 c^{\prime}=1.17181 \times 10^{-10} \mathrm{~m} \tag{13.843}
\end{equation*}
$$

Substitution of Eqs. (13.840-13.841) into Eq. (11.80) is:

$$
\begin{equation*}
b=c=2.18964 a_{0}=1.15871 \times 10^{-10} \mathrm{~m} \tag{13.844}
\end{equation*}
$$

Substitution of Eqs. (13.840-13.841) into Eq. (11.67) is:

$$
\begin{equation*}
e=0.45140 \tag{13.845}
\end{equation*}
$$

Using the electron configuration of $C N$ (Eq. (13.810)), the radii of the $C 1 s=0.17113 a_{0}$ (Eq. (10.51)), $C 2 s=0.84317 a_{0}$ (Eq. (10.62)), $\quad C 2 p=0.88084 a_{0} \quad$ (Eq. (13.819)), $\quad N 1 s=0.14605 a_{0} \quad$ (Eq. (10.51)), $\quad N 2 s=0.69385 a_{0} \quad$ (Eq. (10.62)), and $N 2 p=0.76366 a_{0}$ (Eq. (13.829)) shells and the parameters of the $\sigma$ MO of $C N$ given by Eqs. (13.3-13.4), (13.840-13.842), and (13.844-13.845), the dimensional diagram and charge-density of the $C N \mathrm{MO}$ are shown in Figures 13.22 and 13.23, respectively.

Figure 13.22. The cross section of the $C N$ MO showing the axes, $\sigma$ MO ( $H_{2}$-type ellipsoidal MO), with the $C 1 s, 2 s$, and $2 p$ atomic orbitals (AOs) and the $N 1 s, 2 s$, and $2 p$ AOs. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $r_{5}$ : radius of the $C 2 p$ shell having one unpaired electron, $r_{6}$ : radius of the $N 2 p$ shell having two paired electrons.

Figure 13.23. $C N$ MO comprising the $\sigma \mathrm{MO}\left(H_{2}\right.$-type MO) with $C$ and $N$ atoms at the foci that have each donated an electron to the $\sigma$ MO and have smaller radii and higher binding energies as a consequence. (A) Color scale, translucent view of the charge-density of the $C N$ MO. (B) Off-center cut-away view showing the complete inner most $C 1 s$ shell, and moving radially, the $C 2 s$ shell, the $C 2 p$ shell, and the $\sigma$ prolate spheroidal MO that has the $C$ atom as a focus. Moving radially from the nitrogen-atom focus, the complete inner most $N 1 s$ shell, the $N 2 s$ shell, the $N 2 p$ shell, and the $\sigma$ prolate spheroidal MO are shown.

## SUM OF THE ENERGIES OF THE $\sigma$ MO AND THE AOs OF THE CARBON NITRIDE RADICAL

The energies of the $C N \sigma$ MO are given by the substitution of the semiprincipal axes (Eqs. (13.840-13.841) and (13.844)) into the energy equations (Eqs. (11.207-11.212)) of $\mathrm{H}_{2}$ :

$$
\begin{align*}
& V_{e}=\frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-23.90105 \mathrm{eV}  \tag{13.846}\\
& V_{p}=\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=12.28328 \mathrm{eV}  \tag{13.847}\\
& T=\frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=4.87009 \mathrm{eV}  \tag{13.848}\\
& V_{m}=\frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-2.43504 \mathrm{eV}  \tag{13.849}\\
& E_{T}=V_{e}+T+V_{m}+V_{p} \tag{13.850}
\end{align*}
$$

Substitution of Eqs. (11.79) and (13.846-13.849) into Eq. (13.850) gives:

$$
\begin{equation*}
E_{T}(C N, \sigma)=\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right)=-9.18273 \mathrm{eV} \tag{13.851}
\end{equation*}
$$

where $E_{T}(C N, \sigma)$ is the total energy of the $\sigma$ MO of $C N$. The sum, $E_{T}(C N)$, of $E_{T}(C N, C 2 p)$, the $C 2 p$ AO contribution given by Eq. (13.831), $E_{T}(C N, N 2 p)$, the $N 2 p \mathrm{AO}$ contribution given by Eq. (13.833), and $E_{T}(C N, \sigma)$, the $\sigma$ MO contribution given by Eq. (13.851) is:

$$
\begin{align*}
E_{T}(C N) & =E_{T}(C N, C 2 p)+E_{T}(C N, N 2 p)+E_{T}\left(N_{2}, \sigma\right) \\
& =-8.33948 \mathrm{eV}-15.99929 \mathrm{eV}-9.18273 \mathrm{eV}  \tag{13.852}\\
& =-33.52149 \mathrm{eV}
\end{align*}
$$

## VIBRATION OF $C N$

The vibrational energy levels of $C N$ may be solved by determining the Morse potential curve from the energy relationships for the transition from a $C$ atom and $N$ atom whose parameters are given by Eqs. (10.115-10.123) and (10.134-10.143), respectively, to a $C$ atom whose parameter $r_{5}$ is given by Eq. (10.819), a $N$ atom whose parameter $r_{6}$ is given by Eq. (13.829), and the $\sigma$ MO whose parameters are given by Eqs. (13.840-13.842) and (13.844-13.845). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K\&P) [15] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

## THE DOPPLER ENERGY TERMS OF THE CARBON NITRIDE RADICAL

The equations of the radiation reaction force of $C N$ are the same as those of $H_{2}$ with the substitution of the $C N$ parameters. Using Eqs. (11.231-11.233), the angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}=1.07550 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{13.853}
\end{equation*}
$$

where $a$ is given by Eq. (13.840). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 1.07550 \times 10^{16} \mathrm{rad} / \mathrm{s}=7.07912 \mathrm{eV} \tag{13.854}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}(C N)$ for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.854) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of the reentrant orbit:

$$
\begin{align*}
\bar{E}_{D} & \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-33.59603 \mathrm{eV} \sqrt{\frac{2 e(7.07912 \mathrm{eV})}{m_{e} c^{2}}}  \tag{13.855}\\
& =-0.17684 \mathrm{eV}
\end{align*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $C N \mathrm{MO}$ due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.855) and $\bar{E}_{K v i b}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy. Using the experimental $C N$ $\omega_{e}$ of $2068.59 \mathrm{~cm}^{-1}(0.25647 \mathrm{eV})$ [28] for $\bar{E}_{\text {Kvib }}$ of the transition state, $\bar{E}_{\text {osc }}(C N)$ is:

$$
\begin{align*}
\bar{E}_{\text {osc }}(C N) & =\bar{E}_{D}+\bar{E}_{\text {Kvib }} \\
& =\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.856}\\
\bar{E}_{\text {osc }}(C N) & =-0.17684 \mathrm{eV}+\frac{1}{2}(0.25647 \mathrm{eV})  \tag{13.857}\\
& =-0.04860 \mathrm{eV}
\end{align*}
$$

## TOTAL AND BOND ENERGIES OF THE CARBON NITRIDE RADICAL

$E_{T+\text { osc }}(C N)$, the total energy of $C N$ including the Doppler term, is given by the sum of $E_{T}(C N)$ (Eq. (13.852)) and $\bar{E}_{\text {osc }}(C N)$ given by Eq. (13.857):

$$
\left.\begin{array}{rl}
E_{T+o s c}(C N) & =V_{e}+T+V_{m}+V_{p}+E_{T}(C N, C 2 p)+E_{T}(C N, N 2 p)+\bar{E}_{o s c}(C N) \\
& =E_{T}(C N, \sigma)+E_{T}(C N, C 2 p)+E_{T}(C N, N 2 p)+\bar{E}_{o s c}(C N) \\
& =E_{T}(C N)+\bar{E}_{o s c}(C N) \\
E_{T+o s c}(C N) & \left.=\left\{\begin{array}{l}
\left(\begin{array}{l}
-\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1
\end{array}\right) \\
\left.-\sqrt{-\sum_{C, n=4}^{4} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{5}}\right.}-\frac{1}{r_{6}}\right)-\sum_{N, n=4}^{\frac{e^{2}}{4 \pi \varepsilon_{0} a^{3}}} \\
1+\sqrt{\frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}}\left(\frac{1}{r_{6}}-\frac{1}{r_{7}}\right)
\end{array}\right)+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{array}\right)
$$

From Eqs. (13.856-13.859), the total energy of the $C N \mathrm{MO}$ is:

$$
\begin{align*}
E_{T+\text { osc }}(C N) & =-33.52149 \mathrm{eV}+\bar{E}_{\text {osc }}(C N) \\
& =-33.52149 \mathrm{eV}-0.17684 \mathrm{eV}+\frac{1}{2}(0.25647 \mathrm{eV})  \tag{13.860}\\
& =-33.56970 \mathrm{eV}
\end{align*}
$$

where the experimental $\omega_{e}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The $C N$ bond dissociation energy, $E_{D}(C N)$, is given by the difference between the sum of the energies of the $C$ and $N$ atoms and $E_{T+o s c}(C N)$ :

$$
\begin{equation*}
E_{D}(C N)=E(C)+E(N)-E_{T+o s c}(C N) \tag{13.861}
\end{equation*}
$$

where the energy of a carbon atom is [6]:

$$
\begin{equation*}
E(C)=-11.26030 \mathrm{eV} \tag{13.862}
\end{equation*}
$$

and the energy of a nitrogen atom is [6]:

$$
\begin{equation*}
E(N)=-14.53414 \mathrm{eV} \tag{13.863}
\end{equation*}
$$

Thus, the $C N$ bond dissociation energy, $E_{D}(C N)$, given by Eqs. (13.860-13.863) is:

$$
\begin{align*}
E_{D}(C N) & =-(11.26030 \mathrm{eV}+14.53414 \mathrm{eV})-E_{T+o s c}(C N) \\
& =-25.79444 \mathrm{eV}-(-33.56970 \mathrm{eV})  \tag{13.864}\\
& =7.77526 \mathrm{eV}
\end{align*}
$$

The experimental $C N$ bond dissociation energy is [50]:

$$
\begin{equation*}
E_{D 298}(C N)=7.7731 \mathrm{eV} \tag{13.865}
\end{equation*}
$$

The results of the determination of bond parameters of $C N$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## CARBON MONOXIDE MOLECULE

The carbon monoxide molecule can be formed by the reaction of carbon and oxygen atoms:

$$
\begin{equation*}
\mathrm{C}+\mathrm{O} \rightarrow \mathrm{CO} \tag{13.866}
\end{equation*}
$$

The bond in the carbon monoxide molecule comprises a double bond, a $\mathrm{H}_{2}$-type molecular orbital (MO) with four paired electrons. The force balance equation and radius $r_{6}$ of the $2 p$ shell of $C$ is derived in the Six-Electron Atoms section. The force balance equation and radius $r_{8}$ of the $2 p$ shell of $O$ is derived in the Eight-Electron Atoms section. With the formation of the $H_{2}$-type MO by the contribution of two $2 p$ electrons from each of the $C$ and $O$ atoms, a diamagnetic force arises between the remaining outer shell atomic electrons, the $2 s$ electrons of $C$ and the $2 p$ electrons of $O$, and the $H_{2}$-type MO. This force from C and O causes the $\mathrm{H}_{2}$-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the factor of two increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining $O 2 p$ electrons decrease the radius of the corresponding shell such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of CO is $\mathrm{C} 1 s^{2} O 1 s^{2} \mathrm{C} 2 s^{2} O 2 s^{2} O 2 p^{2} \sigma_{C, O}^{4}$ where $\sigma$ designates the $\mathrm{H}_{2}$-type MO , and the orbital arrangement is:

Carbon monoxide is predicted to be diamagnetic in agreement with observations [42].

## FORCE BALANCE OF THE $2 p$ SHELL OF THE OXYGEN ATOM OF THE CARBON MONOXIDE MOLECULE

For the $O$ atom, force balance for the outermost $2 p$ electron of $C O$ (electron 6) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 6 and the other $2 p$ electron as well as the $2 s$ shell electrons due to spin and orbital angular momentum. The forces used are derived in the Eight-Electron Atoms section. The central Coulomb force on the outer-most $2 p$ shell electron of $C O$ (electron 6) due to the nucleus and the inner five electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{\text {ele }}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}} \mathbf{i}_{\mathbf{r}} \tag{13.868}
\end{equation*}
$$

for $r>r_{5}$. The $2 p$ shell possesses a +2 external electric field given by Eq. (10.92) for $r>r_{6}$. The energy is minimized with conservation of angular momentum. This condition is met when the diamagnetic force, $\mathbf{F}_{d i}$ $\qquad$ , of Eq. (10.82) due to the $p$ orbital contribution is given by:

$$
\begin{align*}
\mathbf{F}_{\text {diamagnetic }} & =-\left(\frac{1}{3}\right) \frac{\hbar^{2}}{4 m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \\
& =-\frac{\hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}} \mathbf{i}_{\mathbf{r}} \tag{13.869}
\end{align*}
$$

And, $\mathbf{F}_{\text {mag } 2}$ corresponding to the conserved spin and orbital angular momentum given by Eq. (10.157) is:

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 2}=\frac{1}{Z} \frac{2 \hbar^{2}}{m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.870}
\end{equation*}
$$

The electric field external to the $2 p$ shell given by Eq. (10.92) for $r>r_{6}$ gives rise to a second diamagnetic force, $\mathbf{F}_{\text {diamagnetic 2 }}$, given by Eq. (10.93). $\mathbf{F}_{\text {diamagnetic } 2}$ due to the binding of the p-orbital electron having an electric field of +2 outside of its radius is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 2}=-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{m_{e} r_{6}^{4}} 10 \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.871}
\end{equation*}
$$

In addition, the contribution of two $2 p$ electrons in the formation of the $\sigma$ molecular orbital (MO) gives rise to a paramagnetic force on the remaining paired $2 p$ electrons. The force $\mathbf{F}_{\text {mag }}$ is given by Eq. (13.625) wherein the radius is $r_{6}$ :

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 3}=\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.872}
\end{equation*}
$$

The radius of the $2 p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.868)) and diamagnetic (Eqs. (13.869) and (13.871)), and paramagnetic (Eqs. (13.870) and (13.872)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{6}^{2}}{r_{6}}=\binom{\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}}-\frac{\hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)}+\frac{2 \hbar^{2}}{Z m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)}}{-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{6}^{4} m_{e}} 10 \sqrt{s(s+1)}+\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{s(s+1)}} \tag{13.873}
\end{equation*}
$$

Substitution of $v_{6}=\frac{\hbar}{m_{e} r_{6}}$ (Eq. (1.35)) and $s=\frac{1}{2}$ into Eq. (13.873) gives:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} r_{6}^{3}}-\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{\frac{3}{4}}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}}-\frac{\hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{2 \hbar^{2}}{Z m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}}-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{6}^{4} m_{e}} 10 \sqrt{\frac{3}{4}} \tag{13.874}
\end{equation*}
$$

The quadratic equation corresponding to Eq. (13.874) is

$$
\begin{equation*}
r_{6}^{2}-\frac{\frac{\hbar^{2}}{m_{e}}\left(1-\frac{\sqrt{3}}{8}\right)}{\left(\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{1}{12}-\frac{2}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)^{2}} r_{6}-\frac{\frac{\hbar^{2}}{m_{e}}\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3} 10 \sqrt{\frac{3}{4}}}{\left(\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{1}{12}-\frac{2}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)}=0 \tag{13.875}
\end{equation*}
$$

The solution of Eq. (13.875) using the quadratic formula is:

$$
\begin{equation*}
r_{6}=\frac{a_{0}\left(1-\frac{\sqrt{3}}{8}\right)}{\left((Z-5)-\left(\frac{1}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right) \pm a_{0} \sqrt{\left(\frac{1-\frac{\sqrt{3}}{8}}{\left(\frac{\left.(Z-5)-\left(\frac{1}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}{\left(\sqrt{20 \sqrt{3}\left(\left[\frac{Z-6}{Z-5}\right)\left(1-\frac{\sqrt{2}}{2}\right) r_{3}\right)}\right.}\right)^{\left((Z-5)-\left(\frac{1}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}}\right.}, r_{3} \text { in units of } a_{0}} \tag{13.876}
\end{equation*}
$$

The positive root of Eq. (13.876) must be taken in order that $r_{6}>0$. Substitution of $\frac{r_{3}}{a_{0}}=0.59020$ (Eq. (10.62) with $Z=8$ ) into Eq. (13.876) gives:

$$
\begin{equation*}
r_{6}=0.68835 a_{0} \tag{13.877}
\end{equation*}
$$

## ENERGIES OF THE $2 s$ AND $2 p$ SHELLS OF THE CARBON ATOM AND THE $2 p$ SHELL OF THE OXYGEN ATOM OF THE CARBON MONOXIDE MOLECULE

With the formation of the $H_{2}$-type MO by the contribution of two $2 p$ electrons from the $C$ atom, the remaining outer-shell atomic electrons comprise the $2 s$ electrons, which are unchanged by bonding with oxygen. However, the total energy of the $C O$ molecule, which is subtracted from the sum of the energies of the carbon and oxygen atoms to determine the bond energy, is increased by the ionization energies of $C^{+}$and $O^{+}$given by Eqs. (10.113-10.114) and (10.152-10.153), respectively. Experimentally, the energies are [6] :

$$
\begin{equation*}
\text { E(ionization } \left.; \mathrm{C}^{+}\right)=24.38332 \mathrm{eV} \tag{13.878}
\end{equation*}
$$

$E\left(\right.$ ionization; $\left.O^{+}\right)=35.11730 \mathrm{eV}$
In addition, the central forces on the $2 p$ shell of the $O$ atom are increased with the formation of the $\sigma \mathrm{MO}$, which reduces the shell's radius and increases its total energy. The Coulombic energy terms of the total energy of the $O$ atom at the new radius are calculated and added to the ionization energies of $C^{+}$and $O^{+}$, and the energy of the $\sigma$ MO to give the total energy of $C O$. Then, the bond energy is determined from the total $C O$ energy.

The radius $r_{8}$ of the oxygen atom before bonding is given by Eq. (10.162):

$$
\begin{equation*}
r_{8}=a_{0} \tag{13.880}
\end{equation*}
$$

Using the initial radius $r_{8}$ of the $O$ atom and the final radius $r_{6}$ of the $O 2 p$ shell (Eq. (13.877)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_{T}(O, 2 p)$ of the Coulombic energy change of the $O 2 p$ electrons of the $O$ atom is determined using Eq. (10.102):

$$
\begin{equation*}
E_{T}(O, 2 p)=-\sum_{n=4}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{6}}-\frac{1}{r_{8}}\right)=-(13.60580 \mathrm{eV})(0.45275)(3+4)=-43.11996 \mathrm{eV} \tag{13.881}
\end{equation*}
$$

## FORCE BALANCE OF THE $\sigma$ MO OF THE CARBON MONOXIDE MOLECULE

The force balance can be considered due to a second pair of two electrons binding to a molecular ion having $+2 e$ at each focus and a first bound pair. Then, the forces are the same as those of a molecule ion having $+e$ at each focus. The diamagnetic force $\mathbf{F}_{\text {diamagneticMO1 }}$ for the $\sigma-\mathrm{MO}$ of the $C O$ molecule due to the two paired electrons in each of the $C 2 s$ and $O 2 p$ shells is given by Eq. (13.633) with $n_{e}=2$ :

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO1 }}=\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{13.882}
\end{equation*}
$$

The force $\mathbf{F}_{\text {diamagneticMO2 }}$ is given by Eqs. (13.634) and (13.835) as the sum of the contributions due to carbon with $Z=Z_{1}$ and oxygen with $Z=Z_{2} . \mathbf{F}_{\text {diamagneticмO1 }}$ for $C O$ with $\left|L_{i}\right|=\hbar$ is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO2 }}=\left(\frac{1}{Z_{1}}+\frac{1}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{13.883}
\end{equation*}
$$

The force balance equation for the $\sigma$-MO of the carbon monoxide molecule given by Eqs. (11.200), (13.633-13.634), and (13.882-13.883) is:

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(1+\left(\frac{1}{Z_{1}}+\frac{1}{Z_{2}}\right)\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{13.884}\\
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D-\left(\frac{1}{Z_{1}}+\frac{1}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{13.885}\\
& \left(2+\frac{1}{Z_{1}}+\frac{1}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D  \tag{13.886}\\
& a=\left(2+\frac{1}{Z_{1}}+\frac{1}{Z_{2}}\right) a_{0} \tag{13.887}
\end{align*}
$$

Substitution of $Z_{1}=6$ and $Z_{2}=8$ into Eq. (13.887) gives:

$$
\begin{equation*}
a=2.29167 a_{0}=1.21270 \times 10^{-10} \mathrm{~m} \tag{13.888}
\end{equation*}
$$

Substitution of Eq. (13.888) into Eq. (11.79) is:

$$
\begin{equation*}
c^{\prime}=1.07044 a_{0}=5.66450 \times 10^{-11} \mathrm{~m} \tag{13.889}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.889) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.14087 a_{0}=1.13290 \times 10^{-10} \mathrm{~m} \tag{13.890}
\end{equation*}
$$

The experimental bond distance is [28]:

$$
\begin{equation*}
2 c^{\prime}=1.12823 \times 10^{-10} \mathrm{~m} \tag{13.891}
\end{equation*}
$$

Substitution of Eqs. (13.888-13.889) into Eq. (11.80) is:

$$
\begin{equation*}
b=c=2.02630 a_{0}=1.07227 \times 10^{-10} \mathrm{~m} \tag{13.892}
\end{equation*}
$$

Substitution of Eqs. (13.888-13.889) into Eq. (11.67) is:

$$
\begin{equation*}
e=0.46710 \tag{13.893}
\end{equation*}
$$

Using the electron configuration of $C O$ (Eq. (13.867)), the radii of the $C 1 s=0.17113 a_{0}$ (Eq. (10.51)), $C 2 s=0.84317 a_{0}$ (Eq. (10.62)), $O 1 s=0.12739 a_{0}$ (Eq. (10.51)), $O 2 s=0.59020 a_{0}$ (Eq. (10.62)), and $O 2 p=0.68835 a_{0}$ (Eq. (13.877)) shells and the parameters of the $\sigma \mathrm{MO}$ of $C O$ given by Eqs. (13.3-13.4), (13.888-13.890), and (13.892-13.893), the dimensional diagram and charge-density of the $C O$ MO are shown in Figures 13.24 and 13.25, respectively.

Figure 13.24. The cross section of the $C O$ MO showing the axes, $\sigma \mathrm{MO}$ ( $H_{2}$-type ellipsoidal MO) with four paired electrons, with the $C 1 s$ and $2 s$ atomic orbitals (AOs) and the $O 1 s, 2 s$, and $2 p$ AOs. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $r_{4}$ : radius of the $C 2 s$ shell having two paired electrons, $r_{6}$ : radius of the $O 2 p$ shell having two paired electrons.

Figure 13.25. $C O$ MO comprising the $\sigma \mathrm{MO}\left(H_{2}\right.$-type MO) with $C$ and $O$ atoms at the foci that have each donated two electrons to the $\sigma$ MO. Consequently, the outer electrons of the carbon atom comprise the $C 2 s$ shell, and the $O 2 p$ shell has a smaller radius and a higher binding energy. (A) Color scale, translucent view of the charge-density of the $C O$ MO. (B) Off-center cut-away view showing the complete inner most $O 1 s$ shell, and moving radially, the $O 2 s$ shell, the $O 2 p$ shell, and the $\sigma$ prolate spheroidal MO that has the $O$ atom as a focus. Moving radially from the carbon-atom focus, the complete inner most $C 1 s$ shell, the $C 2 s$ shell, and the $\sigma$ prolate spheroidal MO are shown.

## SUM OF THE ENERGIES OF THE $\sigma$ MO AND THE AOS OF THE CARBON MONOXIDE MOLECULE

The energies of the $C O \sigma$ MO are given by the substitution of the semiprincipal axes (Eqs. (13.888-13.889) and (13.892)) into the energy equations (Eqs. (11.207-11.212)) of $H_{2}$ except that the terms based on charge are multiplied by four and the kinetic energy term is multiplied by two due to the $\sigma-\mathrm{MO}$ double bond with two pairs of paired electrons:

$$
\begin{align*}
& V_{e}=2^{2} \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-102.97635 \mathrm{eV}  \tag{13.894}\\
& V_{p}=2^{2} \frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=50.84210 \mathrm{eV}  \tag{13.895}\\
& T=2 \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=11.23379 \mathrm{eV} \tag{13.896}
\end{align*}
$$

$$
\begin{align*}
& V_{m}=2^{2} \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-11.23379 \mathrm{eV}  \tag{13.897}\\
& E_{T}=V_{e}+T+V_{m}+V_{p} \tag{13.898}
\end{align*}
$$

Substitution of Eqs. (11.79) and (13.894-13.897) into Eq. (13.898) gives:
where $E_{T}(C O, \sigma)$ is the total energy of the $\sigma \mathrm{MO}$ of $C O$. The total energy of $C O, E_{T}(C O)$, is given by the sum of E(ionization; $C^{+}$), the energy of the second electron of carbon (Eq. (13.878)) donated to the double bond, E(ionization; $O^{+}$), the energy of the second electron of oxygen (Eq. (13.879)) donated to the double bond, $E_{T}(O, 2 p)$, the $O 2 p$ AO contribution due to the decrease in radius with bond formation (Eq. (13.881)), and $E_{T}(C O, \sigma)$, the $\sigma \mathrm{MO}$ contribution given by Eq. (13.899):

$$
\begin{align*}
E_{T}(C O) & =E\left(\text { ionization } ; C^{+}\right)+E\left(\text { ionization } ; O^{+}\right)+E_{T}(O, 2 p)+E_{T}(C O, \sigma) \\
& =24.38332 \mathrm{eV}+35.11730 \mathrm{eV}-43.11996 \mathrm{eV}-52.13425 \mathrm{eV}  \tag{13.900}\\
& =-35.75359 \mathrm{eV}
\end{align*}
$$

## VIBRATION OF $C O$

The vibrational energy levels of $C O$ may be solved by determining the Morse potential curve from the energy relationships for the transition from a $C$ atom and $O$ atom whose parameters are given by Eqs. (10.115-10.123) and (10.154-10.163), respectively, to a $C$ atom whose parameter $r_{4}$ is given by Eq. (10.61), an $O$ atom whose parameter $r_{6}$ is given by Eq. (13.877), and the $\sigma$ MO whose parameters are given by Eqs. (13.888-13.890) and (13.892-13.893). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K\&P) [15] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

## THE DOPPLER ENERGY TERMS OF THE CARBON MONOXIDE MOLECULE

The equations of the radiation reaction force of carbon monoxide are the same as those of $H_{2}$ with the substitution of the CO parameters except that there is a factor of four increase in the central force in Eq. (11.231) due to the double bond. Using Eqs. (11.231-11.233), the angular frequency of the reentrant oscillation in the transition state is

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{4 e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}=2.38335 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{13.901}
\end{equation*}
$$

where $a$ is given by Eq. (13.888). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{align*}
\bar{E}_{K} & =\hbar \omega=\hbar 2.38335 \times 10^{16} \mathrm{rad} / \mathrm{s}  \tag{13.902}\\
& =15.68762 \mathrm{eV}
\end{align*}
$$

In Eq. (11.181), substitution of $E_{T}(C O)$ for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.902) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of the reentrant orbit:

$$
\begin{align*}
\bar{E}_{D} & \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}  \tag{13.903}\\
& =-35.75359 \mathrm{eV} \sqrt{\frac{2 e(15.68762 \mathrm{eV})}{m_{e} c^{2}}}=-0.28016 \mathrm{eV}
\end{align*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $C O \mathrm{MO}$ due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.903) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy. Using the experimental $C O$ $\omega_{e}$ of $2169.81 \mathrm{~cm}^{-1}(0.26902 \mathrm{eV})$ [28] for $\bar{E}_{\text {Kvib }}$ of the transition state, $\bar{E}_{\text {osc }}^{\prime}(\mathrm{CO})$ per bond is:

$$
\begin{align*}
& \bar{E}_{o s c}^{\prime}(C O)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.904}\\
& \bar{E}_{o s c}^{\prime}(C O)=-0.28016 \mathrm{eV}+\frac{1}{2}(0.26902 \mathrm{eV})=-0.14564 \mathrm{eV} \tag{13.905}
\end{align*}
$$

Since the $\sigma$ MO bond is a double bond with twice a many electrons as a single bond, $\bar{E}_{\text {osc }}^{\prime}(C O)$ is multiplied by two to give:

$$
\begin{equation*}
\bar{E}_{\text {osc }}(C O)=-0.29129 \mathrm{eV} \tag{13.906}
\end{equation*}
$$

## TOTAL AND BOND ENERGIES OF THE CARBON MONOXIDE MOLECULE

$E_{T+o s c}(C O)$, the total energy of $C O$ including the Doppler term, is given by the sum of $E_{T}(C O)$ (Eq. (13.900)) and $\bar{E}_{\text {osc }}(C O)$ given by Eq. (13.906):

$$
\left.\left.\begin{array}{rl}
E_{T+o s c}(C O) & =\left(\begin{array}{l}
V_{e}+T+V_{m}+V_{p}+E\left(\text { ionization } ; C^{+}\right) \\
\\
+E\left(\text { ionization; } O^{+}\right)+E_{T}(O, 2 p)+\bar{E}_{\text {osc }}(C O)
\end{array}\right) \\
& =\binom{E_{T}(C O, \sigma)+E\left(\text { ionization; } C^{+}\right)+E\left(\text { ionization; } O^{+}\right)}{+E_{T}(O, 2 p)+\bar{E}_{\text {osc }}(C O)} \\
& =E_{T}(C O)+\bar{E}_{\text {osc }}(C O)
\end{array}\right)\left(\begin{array}{l}
\left(\begin{array}{l}
-e^{2} \\
8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}} \\
\left.8 \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-4\right)+E\left(\text { ionization; } C^{+}\right)
\end{array}\right) \\
+E\left(\text { ionization; } O^{+}\right)-\sum_{o, n=4}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{6}}-\frac{1}{r_{8}}\right)  \tag{13.908}\\
E_{T+o s c}(C O)
\end{array}\right)\right\}
$$

From Eqs. (13.906-13.908), the total energy of the $C O$ MO is:

$$
\begin{align*}
E_{T+o s c}(C O) & =-35.75359 \mathrm{eV}+\bar{E}_{\text {osc }}(C O) \\
& =-35.75359 \mathrm{eV}+(-0.29129 \mathrm{eV})=-36.04488 \mathrm{eV} \tag{13.909}
\end{align*}
$$

where the experimental $\omega_{e}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The $C O$ bond dissociation energy, $E_{D}(C O)$, is given by the difference between the sum of the energies of the $C$ and $O$ atoms and $E_{T+o s c}(C O)$ :

$$
\begin{equation*}
E_{D}(C O)=E(C)+E(O)-E_{T+o s c}(C O) \tag{13.910}
\end{equation*}
$$

where the energy of a carbon atom is [6]:

$$
\begin{equation*}
E(C)=-11.26030 \mathrm{eV} \tag{13.911}
\end{equation*}
$$

and the energy of an oxygen atom is [6]:

$$
\begin{equation*}
E(O)=-13.61806 \mathrm{eV} \tag{13.912}
\end{equation*}
$$

Thus, the $C O$ bond dissociation energy, $E_{D}(C O)$, given by Eqs. (13.909-13.912) is:

$$
\begin{align*}
E_{D}(C O) & =-(11.26030 \mathrm{eV}+13.61806 \mathrm{eV})-E_{T+o s c}(\mathrm{CO})  \tag{13.913}\\
& =-24.87836 \mathrm{eV}-(-36.04488 \mathrm{eV})=11.16652 \mathrm{eV}
\end{align*}
$$

The experimental $C O$ bond dissociation energy is [49]:

$$
\begin{equation*}
E_{D 298}(C O)=11.15696 \mathrm{eV} \tag{13.914}
\end{equation*}
$$

The results of the determination of bond parameters of $C O$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## NITRIC OXIDE RADICAL

The nitric oxide radical can be formed by the reaction of nitrogen and oxygen atoms:

$$
\begin{equation*}
N+O \rightarrow N O \tag{13.915}
\end{equation*}
$$

The bond in the nitric oxide radical comprises a double bond, a $\mathrm{H}_{2}$-type molecular orbital (MO) with four paired electrons. The force balance equation and radius $r_{7}$ of the $2 p$ shell of $N$ is derived in the Seven-Electron Atoms section. The force balance equation and radius $r_{8}$ of the $2 p$ shell of $O$ is derived in the Eight-Electron Atoms section. With the formation of the $H_{2}$-type MO by the contribution of two $2 p$ electrons from each of the $N$ and $O$ atoms, a diamagnetic force arises between the remaining outer shell atomic electrons, the $2 s$ and $2 p$ electrons of $N$ and $O$, and the $H_{2}$-type MO. This force from $N$ and $O$ causes the $H_{2}$-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the factor of two increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining $N$ and $O$ electrons decrease the radii of the corresponding shells such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of $N O$ is $N 1 s^{2} O 1 s^{2} N 2 s^{2} O 2 s^{2} N 2 p^{1} O 2 p^{2} \sigma_{N, O}^{4}$ where $\sigma$ designates the $\mathrm{H}_{2}$-type MO , and the orbital arrangement is:

Nitric oxide is predicted to be weakly paramagnetic in agreement with observations [42].

## FORCE BALANCE OF THE $2 p$ SHELL OF THE NITROGEN ATOM OF THE NITRIC OXIDE RADICAL

For the $N$ atom, force balance for the outermost $2 p$ electron of $N O$ (electron 5) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 5 and the $2 s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Seven-Electron Atoms section. The central Coulomb force on the outer-most $2 p$ shell electron of $N O$ (electron 5) due to the nucleus and the inner four electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{e l e}=\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0} r_{5}^{2}} \mathbf{i}_{\mathbf{r}} \tag{13.917}
\end{equation*}
$$

for $r>r_{4}$. The $2 p$ shell possess a +2 external electric field given by Eq. (10.92) for $r>r_{5}$. The energy is minimized with conservation of angular momentum. This condition is met when the magnetic forces of $N$ in $N O$ are the same as those of $N$ in the nitrogen molecule with $r_{5}$ replacing $r_{6}$ and with an increase of the central field by an integer. The diamagnetic force, $\mathbf{F}_{\text {diamagnetic }}$, of Eq. (10.82) due to the $p$-orbital contribution is given by Eq. (13.622) with $r_{5}$ replacing $r_{6}$ :

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic }}=-\left(\frac{1}{3}\right) \frac{\hbar^{2}}{4 m_{e} r_{5}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}}=-\frac{\hbar^{2}}{12 m_{e} r_{5}^{2} r_{3}} \sqrt{\frac{3}{4}} \mathbf{i}_{\mathbf{r}} \tag{13.918}
\end{equation*}
$$

And, $\mathbf{F}_{\text {mag } 2}$ corresponding to the conserved orbital angular momentum of the three orbitals is also the same as that of $N_{2}$ given by Eq. (13.623) with $r_{5}$ replacing $r_{6}$ :

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 2}=\frac{1}{Z} \frac{3 \hbar^{2}}{m_{e} r_{5}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathrm{r}} \tag{13.919}
\end{equation*}
$$

The electric field external to the $2 p$ shell given by Eq. (10.92) for $r>r_{5}$ gives rise to a second diamagnetic force, $\mathbf{F}_{\text {diamagnetic 2 }}$, given by Eq. (10.93). $\mathbf{F}_{\text {diamagnetic } 2}$ due to the binding of the p-orbital electron having an electric field of +2 outside of its radius follows from Eq. (13.624).

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 2}=-\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{m_{e} r_{5}^{4}} 10 \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.920}
\end{equation*}
$$

In addition to the $N$ forces $\mathbf{F}_{\text {ele }}, \mathbf{F}_{\text {diamagnetic }}, \mathbf{F}_{\text {mag 2 }}$, and $\mathbf{F}_{\text {diamagnetic } 2}$ of $N O$ being the same as $N_{2}$ given by Eqs. (13.621-13.624), respectively, $\mathbf{F}_{\text {ele }}, \mathbf{F}_{\text {mag 2 }}$, and $\mathbf{F}_{\text {diamagnetic } 2}$ are also the same as those of $C N$ (Eqs. (13.820) and (13.822-13.823)). In the $N_{2}$ and $C N$ cases, the contribution of a $2 p$ electron from the $N$ atom in the formation of the $\sigma$ MO gives rise to an additional paramagnetic force on the remaining two $2 p$ electrons that pair. However, the force, $\mathbf{F}_{\text {mag }}{ }_{3}$, is absent in $N O$ since the single outer electron is unpaired.

The radius of the $2 p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.917)) and diamagnetic (Eqs. (13.918) and (13.920)), and paramagnetic (Eq. (13.919)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{5}^{2}}{r_{5}}=\binom{\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0} r_{5}^{2}}-\frac{\hbar^{2}}{12 m_{e} r_{5}^{2} r_{3}} \sqrt{s(s+1)}+\frac{3 \hbar^{2}}{Z m_{e} r_{5}^{2} r_{3}} \sqrt{s(s+1)}}{-\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{5}^{4} m_{e}} 10 \sqrt{s(s+1)}} \tag{13.921}
\end{equation*}
$$

Substitution of $v_{5}=\frac{\hbar}{m_{e} r_{5}}$ (Eq. (1.35)) and $s=\frac{1}{2}$ into Eq. (13.921) gives:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} r_{5}^{3}}=\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0} r_{5}^{2}}-\frac{\hbar^{2}}{12 m_{e} r_{5}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{3 \hbar^{2}}{Z m_{e} r_{5}^{2} r_{3}} \sqrt{\frac{3}{4}}-\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{5}^{4} m_{e}} 10 \sqrt{\frac{3}{4}} \tag{13.922}
\end{equation*}
$$

The quadratic equation corresponding to Eq. (13.922) is

$$
\begin{equation*}
r_{5}^{2}-\frac{\frac{\hbar^{2}}{m_{e}}}{\left(\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)^{2}} r_{5}-\frac{\frac{\hbar^{2}}{m_{e}}\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3} 10 \sqrt{\frac{3}{4}}}{\left(\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)}=0 \tag{13.923}
\end{equation*}
$$

The solution of Eq. (13.923) using the quadratic formula is:

$$
\begin{equation*}
r_{5}=\frac{a_{0}}{\left((Z-4)-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)} \pm a_{0} \sqrt{\left(\frac{\left((Z-4)-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}{}\right)^{2}} \sqrt[{\left(\frac{\left.20 \sqrt{3}\left(\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3}\right)}{\left((Z-4)-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}\right.}]{2}, r_{3} \text { in units of } a_{0} \tag{13.924}
\end{equation*}
$$

The positive root of Eq. (13.924) must be taken in order that $r_{5}>0$. Substitution of $\frac{r_{3}}{a_{0}}=0.69385$ (Eq. (10.62) with $Z=7$ ) into Eq. (13.924) gives:

$$
\begin{equation*}
r_{5}=0.74841 a_{0} \tag{13.925}
\end{equation*}
$$

## FORCE BALANCE OF THE $2 p$ SHELL OF THE OXYGEN ATOM OF THE NITRIC OXIDE RADICAL

For the $O$ atom, force balance for the outermost $2 p$ electron of $N O$ (electron 6) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 6 and the other $2 p$ electron as well as the $2 s$ shell electrons due to spin and orbital angular momentum. The forces used are derived in the Eight-Electron Atoms section. The central Coulomb force on the outer-most $2 p$ shell electron of $N O$ (electron 6) due to the nucleus and the inner five electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{e l e}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}} \mathbf{i}_{\mathbf{r}} \tag{13.926}
\end{equation*}
$$

for $r>r_{5}$. The $2 p$ shell possess an external electric field of +2 given by Eq. (10.92) for $r>r_{6}$. The energy is minimized with conservation of angular momentum. This condition is met when the diamagnetic force, $\mathbf{F}_{\text {diamagnetic }}$, of Eq. (10.82) due to the $p$ orbital contribution is given by:

$$
\begin{align*}
\mathbf{F}_{\text {diamagnetic }} & =-\left(\frac{2}{3}\right) \frac{\hbar^{2}}{4 m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \\
& =-\frac{2 \hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}} \mathbf{i}_{\mathbf{r}} \tag{13.927}
\end{align*}
$$

And, $\mathbf{F}_{\text {mag } 2}$ corresponding to the conserved spin and orbital angular momentum given by Eqs. (10.157) and (13.670) is:

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 2}=\frac{1}{Z} \frac{2 \hbar^{2}}{m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.928}
\end{equation*}
$$

The electric field external to the $2 p$ shell given by Eq. (10.92) for $r>r_{6}$ gives rise to a second diamagnetic force, $\mathbf{F}_{\text {diamagnetic 2 }}$, given by Eq. (10.93). $\mathbf{F}_{\text {diamagnetic } 2}$ due to the binding of the p-orbital electron having an electric field of +2 outside of its radius is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 2}=-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{m_{e} r_{6}^{4}} 10 \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.929}
\end{equation*}
$$

In addition, the contribution of two $2 p$ electrons in the formation of the $\sigma$ MO gives rise to a paramagnetic force on the remaining paired $2 p$ electrons. The force $\mathbf{F}_{\text {mag }}$ is given by Eq. (13.625) wherein the radius is $r_{6}$ :

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 3}=\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{13.930}
\end{equation*}
$$

The radius of the $2 p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.926)) and diamagnetic (Eqs. (13.927) and (13.929)), and paramagnetic (Eqs. (13.928) and (13.930)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{6}^{2}}{r_{6}}=\binom{\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}}-\frac{2 \hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)}+\frac{2 \hbar^{2}}{Z m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)}}{-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{6}^{4} m_{e}} 10 \sqrt{s(s+1)}+\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{s(s+1)}} \tag{13.931}
\end{equation*}
$$

Substitution of $v_{6}=\frac{\hbar}{m_{e} r_{6}}$ (Eq. (1.35)) and $s=\frac{1}{2}$ into Eq. (13.931) gives:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} r_{6}^{3}}-\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{\frac{3}{4}}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}}-\frac{2 \hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{2 \hbar^{2}}{Z m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}}-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{6}^{4} m_{e}} 10 \sqrt{\frac{3}{4}} \tag{13.932}
\end{equation*}
$$

The quadratic equation corresponding to Eq. (13.932) is:

$$
\begin{equation*}
r_{6}^{2}-\frac{\frac{\hbar^{2}}{m_{e}}\left(1-\frac{\sqrt{3}}{8}\right)}{\left(\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)^{2}} r_{6}-\frac{\frac{\hbar^{2}}{m_{e}}\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3} 10 \sqrt{\frac{3}{4}}}{\left(\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)}=0 \tag{13.933}
\end{equation*}
$$

The solution of Eq. (13.933) using the quadratic formula is:

$$
\begin{equation*}
r_{6}=\frac{a_{0}\left(1-\frac{\sqrt{3}}{8}\right)}{\left((Z-5)-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)} \pm a_{0} \sqrt{\left(\frac{1-\frac{\sqrt{3}}{8}}{\left(\frac{\left.(Z-5)-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}{\left(\frac{20 \sqrt{3}\left(\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3}\right)}{\left((Z-5)-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}\right.}\right)^{2}}, r_{3} \text { in units of } a_{0}\right.} \tag{13.934}
\end{equation*}
$$

The positive root of Eq. (13.934) must be taken in order that $r_{6}>0$. Substitution of $\frac{r_{3}}{a_{0}}=0.59020$ (Eq. (10.62) with $Z=8$ ) into Eq. (13.934) gives:

$$
\begin{equation*}
r_{6}=0.70460 a_{0} \tag{13.935}
\end{equation*}
$$

## ENERGIES OF THE $2 p$ SHELLS OF THE NITROGEN ATOM AND OXYGEN ATOM OF THE NITRIC OXIDE RADICAL

With the formation of the $H_{2}$-type MO by the contribution of two $2 p$ electrons from each of the $N$ and $O$ atoms, the total energy of the $N O$ molecule, which is subtracted from the sum of the energies of the nitrogen and oxygen atoms to determine the bond energy, is increased by the ionization energies of $N^{+}$and $O^{+}$given by Eqs. (10.132-10.133) and (10.152-10.153), respectively. Experimentally, the energies are [6]:

$$
\begin{equation*}
E\left(\text { ionization } ; N^{+}\right)=29.6013 \mathrm{eV} \tag{13.936}
\end{equation*}
$$

E(ionization; $\left.O^{+}\right)=35.11730 \mathrm{eV}$
In addition, the central forces on the $2 p$ shells of the $N$ and $O$ atoms are increased with the formation of the $\sigma$ MO which reduces each shell's radius and increases its total energy. The Coulombic energy terms of the total energy of the $N$ and $O$ atoms at the new radii are calculated and added to the ionization energies of $N^{+}$and $O^{+}$, and the energy of the $\sigma$ MO to give the total energy of $N O$. Then, the bond energy is determined from the total $N O$ energy.

The radius $r_{7}$ of the nitrogen atom before bonding is given by Eq. (10.142):

$$
\begin{equation*}
r_{7}=0.93084 a_{0} \tag{13.938}
\end{equation*}
$$

Using the initial radius $r_{7}$ of the $N$ atom and the final radius $r_{5}$ of the $N 2 p$ shell (Eq. (13.925)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_{T}(N, 2 p)$ of the Coulombic energy change of the $N 2 p$ electrons of the $N$ atom is determined using Eq. (10.102):

$$
\begin{equation*}
E_{T}(N, 2 p)=-\sum_{n=4}^{4} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{5}}-\frac{1}{r_{7}}\right)=-(13.60580 \mathrm{eV})(0.26186)(3)=-10.68853 \mathrm{eV} \tag{13.939}
\end{equation*}
$$

The radius $r_{8}$ of the oxygen atom before bonding is given by Eq. (10.162):

$$
\begin{equation*}
r_{8}=a_{0} \tag{13.940}
\end{equation*}
$$

Using the initial radius $r_{8}$ of the $O$ atom and the final radius $r_{6}$ of the $O 2 p$ shell (Eq. (13.935)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_{T}(O, 2 p)$ of the Coulombic energy change of the $O 2 p$ electrons of the $O$ atom is determined using Eq. (10.102):

$$
\begin{equation*}
E_{T}(O, 2 p)=-\sum_{n=4}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{6}}-\frac{1}{r_{8}}\right)=-(13.60580 \mathrm{eV})(0.41925)(3+4)=-39.92918 \mathrm{eV} \tag{13.941}
\end{equation*}
$$

## FORCE BALANCE OF THE $\sigma$ MO OF THE NITRIC OXIDE RADICAL

The force balance can be considered due to a second pair of two electrons binding to a molecular ion having $+2 e$ at each focus and a first bound pair. Then, the forces are the same as those of a molecule ion having $+e$ at each focus. The diamagnetic force $\mathbf{F}_{\text {diamagneticMO1 }}$ for the $\sigma-\mathrm{MO}$ of the $N O$ molecule due to the two paired electrons in the $O 2 p$ shell is given by Eq. (13.633) with: $n_{e}=2$ :

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO1 }}=\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{13.942}
\end{equation*}
$$

$\mathbf{F}_{\text {diamagneticMO2 }}$ of the nitric oxide radical comprising nitrogen with charge $Z_{1}=7$ and $\left|L_{1}\right|=\hbar$ and $\left|L_{2}\right|=\sqrt{\frac{3}{4}} \hbar$ and oxygen with $Z_{2}=8$ and $\left|L_{3}\right|=\hbar$ is given by the corresponding sum of the contributions. Using Eq. (13.835), $\mathbf{F}_{\text {diamagneticMO2 }}$ for $N O$ is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO2 }}=\left(\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{1}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{13.943}
\end{equation*}
$$

The general force balance equation for the $\sigma$-MO of the nitric oxide radical given by Eqs. (11.200), (13.633-13.634), and (13.942-13.943) is the same as that of $C N$ (Eq. (13.836)):

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(1+\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{1}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{13.944}\\
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D-\left(\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{1}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{13.945}\\
& \left(2+\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{1}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D  \tag{13.946}\\
& a=\left(2+\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{1}{Z_{2}}\right) a_{0} \tag{13.947}
\end{align*}
$$

Substitution of $Z_{1}=7$ and $Z_{2}=8$ into Eq. (13.947) gives:

$$
\begin{equation*}
a=2.39158 a_{0}=1.26557 \times 10^{-10} \mathrm{~m} \tag{13.948}
\end{equation*}
$$

Substitution of Eq. (13.948) into Eq. (11.79) is:

$$
\begin{equation*}
c^{\prime}=1.09352 a_{0}=5.78666 \times 10^{-11} \mathrm{~m} \tag{13.949}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (13.949) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.18704 a_{0}=1.15733 \times 10^{-10} \mathrm{~m} \tag{13.950}
\end{equation*}
$$

The experimental bond distance is [28]:

$$
\begin{equation*}
2 c^{\prime}=1.15077 \times 10^{-10} \mathrm{~m} \tag{13.951}
\end{equation*}
$$

Substitution of Eqs. (13.948-13.949) into Eq. (11.80) is:

$$
\begin{equation*}
b=c=2.12693 a_{0}=1.12552 \times 10^{-10} \mathrm{~m} \tag{13.952}
\end{equation*}
$$

Substitution of Eqs. (13.948-13.949) into Eq. (11.67) is:

$$
\begin{equation*}
e=0.45724 \tag{13.953}
\end{equation*}
$$

Using the electron configuration of $N O$ (Eq. (13.916)), the radii of the $N 1 s=0.14605 a_{0}$ (Eq. (10.51)), $N 2 s=0.69385 a_{0}$ (Eq. (10.62)), $\quad N 2 p=0.74841 a_{0} \quad$ (Eq. (13.925)), $\quad O 1 s=0.12739 a_{0} \quad$ (Eq. (10.51)), $\quad O 2 s=0.59020 a_{0} \quad$ (Eq. (10.62)), and $O 2 p=0.70460 a_{0}$ (Eq. (13.935)) shells and the parameters of the $\sigma \mathrm{MO}$ of $N O$ given by Eqs. (13.3-13.4), (13.948-13.950), and (13.952-13.953), the dimensional diagram and charge-density of the $N O \mathrm{MO}$ are shown in Figures 13.26 and 13.27, respectively.

Figure 13.26. The cross section of the $N O$ MO showing the axes, $\sigma$ MO ( $H_{2}$-type ellipsoidal MO) with four paired electrons, with the $N 1 s, 2 s$, and $2 p$ atomic orbitals (AOs) and the $O 1 s, 2 s$, and $2 p$ AOs. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $r_{5}$ : radius of the $N 2 p$ shell having two paired electrons, $r_{6}$ : radius of the $O 2 p$ shell having two paired electrons.

Figure 13.27. $N O$ MO comprising the $\sigma$ MO ( $\mathrm{H}_{2}$-type MO) with $N$ and $O$ atoms at the foci that have each donated two electrons to the $\sigma$ MO and have smaller radii and higher binding energies as a consequence. (A) Color scale, translucent view of the charge-density of the NO MO. (B) Off-center cut-away view showing the complete inner most $N 1 s$ shell, and moving radially, the $N 2 s$ shell, the $N 2 p$ shell, and the $\sigma$ prolate spheroidal MO that has the $N$ atom as a focus. Moving radially from the oxygen-atom focus, the complete inner most $O 1 s$ shell, the $O 2 s$ shell, the $O 2 p$ shell, and the $\sigma$ prolate spheroidal MO are shown.

## SUM OF THE ENERGIES OF THE $\sigma$ MO AND THE AOs OF THE NITRIC OXIDE RADICAL

The energies of the $N O \sigma$ MO are given by the substitution of the semiprincipal axes (Eqs. (13.948-13.949) and (13.952)) into the energy equations (Eqs. (11.207-11.212)) of $\mathrm{H}_{2}$ except that the terms based on charge are multiplied by four and the kinetic energy term is multiplied by two due to the $\sigma-\mathrm{MO}$ double bond with two pairs of paired electrons:

$$
\begin{align*}
& V_{e}=2^{2} \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-98.30623 \mathrm{eV}  \tag{13.954}\\
& V_{p}=2^{2} \frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=49.76880 \mathrm{eV}  \tag{13.955}\\
& T=2 \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=10.27631 \mathrm{eV}  \tag{13.956}\\
& V_{m}=2^{2} \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-10.27631 \mathrm{eV}  \tag{13.957}\\
& E_{T}=V_{e}+T+V_{m}+V_{p} \tag{13.958}
\end{align*}
$$

Substitution of Eqs. (11.79) and (13.954-13.957) into Eq. (13.958) gives:

$$
\begin{align*}
E_{T}(N O, \sigma) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(8 \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-4\right)  \tag{13.959}\\
& =-48.53743 \mathrm{eV}
\end{align*}
$$

where $E_{T}(N O, \sigma)$ is the total energy of the $\sigma \mathrm{MO}$ of $N O$. The total energy of $N O, E_{T}(N O)$, is given by the sum of E(ionization; $N^{+}$), the energy of the second electron of nitrogen (Eq. (13.936)) donated to the double bond, E(ionization; $O^{+}$), the energy of the second electron of oxygen (Eq. (13.937)) donated to the double bond, $E_{T}(N, 2 p)$, the $N 2 p$ AO contribution
due to the decrease in radius with bond formation (Eq. (13.939)), $E_{T}(O, 2 p)$, the $O 2 p$ AO contribution due to the decrease in radius with bond formation (Eq. (13.941)), and $E_{T}(N O, \sigma)$, the $\sigma$ MO contribution given by Eq. (13.959).

$$
\begin{align*}
E_{T}(N O) & =\binom{E\left(\text { ionization } ; N^{+}\right)+E\left(\text { ionization } ; O^{+}\right)}{+E_{T}(N, 2 p)+E_{T}(O, 2 p)+E_{T}(N O, \sigma)}=\binom{29.6013 \mathrm{eV}+35.11730 \mathrm{eV}}{-10.68853 \mathrm{eV}-39.92918 \mathrm{eV}-48.53743 \mathrm{eV}}  \tag{13.960}\\
& =-34.43653 \mathrm{eV}
\end{align*}
$$

## VIBRATION OF $N O$

The vibrational energy levels of $N O$ may be solved by determining the Morse potential curve from the energy relationships for the transition from a $N$ atom and $O$ atom whose parameters are given by Eqs. (10.134-10.143) and (10.154-10.163), respectively, to a $N$ atom whose parameter $r_{5}$ is given by Eq. (13.925), an $O$ atom whose parameter $r_{6}$ is given by Eq. (13.935), and the $\sigma$ MO whose parameters are given by Eqs. (13.948-13.950) and (13.952-13.953). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K\&P) [15] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

## THE DOPPLER ENERGY TERMS OF THE NITRIC OXIDE RADICAL

The equations of the radiation reaction force of nitric oxide are the same as those of $H_{2}$ with the substitution of the $N O$ parameters except that there is a factor of four increase in the central force in Eq. (11.231) due to the double bond. Using Eqs. (11.231-11.233) and (13.901), the angular frequency of the reentrant oscillation in the transition state is

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{4 e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}=2.23557 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{13.961}
\end{equation*}
$$

where $a$ is given by Eq. (13.948). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 2.23557 \times 10^{16} \mathrm{rad} / \mathrm{s}=14.71493 \mathrm{eV} \tag{13.962}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}(N O)$ for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (13.962) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-34.43653 \mathrm{eV} \sqrt{\frac{2 e(14.71493 \mathrm{eV})}{m_{e} c^{2}}}=-0.26134 \mathrm{eV} \tag{13.963}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $N O \mathrm{MO}$ due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (13.963) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy. Using the experimental $N O$ $\omega_{e}$ of $1904.20 \mathrm{~cm}^{-1}(0.23609 \mathrm{eV})$ [28] for $\bar{E}_{\text {Kvib }}$ of the transition state, $\bar{E}_{\text {osc }}^{\prime}(N O)$ per bond is:

$$
\begin{align*}
& \bar{E}_{\text {osc }}^{\prime}(N O)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{13.964}\\
& \bar{E}_{\text {osc }}^{\prime}(N O)=-0.26134 \mathrm{eV}+\frac{1}{2}(0.23609 \mathrm{eV})=-0.14329 \mathrm{eV} \tag{13.965}
\end{align*}
$$

Since the $\sigma$ MO bond is a double bond with twice a many electrons as a single bond, $\bar{E}^{\prime}{ }_{\text {osc }}(N O)$ is multiplied by two to give:

$$
\begin{equation*}
\bar{E}_{o s c}(N O)=-0.28658 \mathrm{eV} \tag{13.966}
\end{equation*}
$$

## TOTAL AND BOND ENERGIES OF THE NITRIC OXIDE RADICAL

$E_{T+o s c}(N O)$, the total energy of $N O$ including the Doppler term, is given by the sum of $E_{T}(N O)($ Eq. $(13.960))$ and $\bar{E}_{\text {osc }}(N O)$ given by Eq. (13.966).

$$
\begin{align*}
& E_{T+o s c}(N O)=\binom{V_{e}+T+V_{m}+V_{p}+E\left(\text { ionization } ; N^{+}\right)+E\left(\text { ionization } ; O^{+}\right)}{+E_{T}(N, 2 p)+E_{T}(O, 2 p)+\bar{E}_{\text {osc }}(N O)} \\
& =\binom{E_{T}(N O, \sigma)+E\left(\text { ionization } ; N^{+}\right)+E\left(\text { ionization; } O^{+}\right)}{+E_{T}(N, 2 p)+E_{T}(O, 2 p)+\bar{E}_{\text {osc }}(N O)}  \tag{13.967}\\
& =E_{T}(N O)+\bar{E}_{o s c}(N O) \\
& \left(\left(\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(8 \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-4\right)\right.\right. \\
& E_{T+o s c}(N O)=\left\{\begin{array}{l}
\binom{\left.+ \text { (ionization; } N^{+}\right)+E\left(\text { ionization; } O^{+}\right)}{-\sum_{N, n=4}^{4} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{5}}-\frac{1}{r_{7}}\right)-\sum_{o, n=4}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{6}}-\frac{1}{r_{8}}\right)} \\
\binom{\left(+2 \sqrt{\frac{\frac{4 e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}\right.}{m_{e} c^{2}}+2\left(\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{array}\right\}  \tag{13.968}\\
& =-34.43653 \mathrm{eV}-2(0.26134 \mathrm{eV})+2\left(\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{align*}
$$

From Eqs. (13.966-13.968), the total energy of the $N O$ MO is:

$$
\begin{equation*}
E_{T+o s c}(N O)=-34.43653 \mathrm{eV}+\bar{E}_{\text {osc }}(N O)=-34.43653 \mathrm{eV}+(-0.28658)=-34.72312 \mathrm{eV} \tag{13.969}
\end{equation*}
$$

where the experimental $\omega_{e}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The $N O$ bond dissociation energy, $E_{D}(N O)$, is given by the difference between the sum of the energies of the $N$ and $O$ atoms and $E_{T+o s c}(N O)$ :

$$
\begin{equation*}
E_{D}(N O)=E(N)+E(O)-E_{T+o s c}(N O) \tag{13.970}
\end{equation*}
$$

where the energy of a nitrogen atom is [6]:

$$
\begin{equation*}
E(N)=-14.53414 \mathrm{eV} \tag{13.971}
\end{equation*}
$$

and the energy of an oxygen atom is [6]:

$$
\begin{equation*}
E(O)=-13.61806 \mathrm{eV} \tag{13.972}
\end{equation*}
$$

Thus, the $N O$ bond dissociation energy, $E_{D}(N O)$, given by Eqs. (13.969-13.972) is:

$$
\begin{align*}
E_{D}(N O) & =-(14.53414 \mathrm{eV}+13.61806 \mathrm{eV})-E_{T+o s c}(N O) \\
& =-28.15220 \mathrm{eV}-(-34.72312 \mathrm{eV})  \tag{13.973}\\
& =6.57092 \mathrm{eV}
\end{align*}
$$

The experimental $N O$ bond dissociation energy is [49]:

$$
\begin{equation*}
E_{D 298}(N O)=6.5353 \mathrm{eV} \tag{13.974}
\end{equation*}
$$

The results of the determination of bond parameters of $N O$ are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

Table 13.1. The calculated and experimental bond parameters of $H_{3}^{+}, D_{3}^{+}, \mathrm{OH}, \mathrm{OD}, \mathrm{H}_{2} \mathrm{O}, \mathrm{D}_{2} \mathrm{O}, \mathrm{NH}, \mathrm{ND}, \mathrm{NH}_{2}, \mathrm{ND}_{2}$, $\mathrm{NH}_{3}, \mathrm{ND}_{3}, \mathrm{CH}, \mathrm{CD}, \mathrm{CH}_{2}, \mathrm{CH}_{3}, \mathrm{CH}_{4}, \mathrm{~N}_{2}, \mathrm{O}_{2}, \mathrm{~F}_{2}, \mathrm{Cl}_{2}, \mathrm{CN}, \mathrm{CO}$, and NO .

## Chapter 14

## MORE POLYATOMIC MOLECULES AND HYDROCARBONS

Additional polyatomic molecules can be solved using similar principles as those used to solve hydrogen molecular ions and molecules wherein the hydrogen molecular orbitals (MOs) and hydrogen atomic orbitals serve as basis functions for the MOs. The MO must (1) be a solution of Laplace's equation to give a equipotential energy surface, (2) correspond to an orbital solution of the Newtonian equation of motion in an inverse-radius-squared central field having a constant total energy, (3) be stable to radiation, and (4) conserve the electron angular momentum of $\hbar$. Energy of the MO must be matched to that of the outermost atomic orbital of a bonding heteroatom in the case where a minimum energy is achieved with a direct bond to the AO. Alternatively, the MO is continuous with the AO containing paired electrons that do not particpate in the bond. Rather, they only provide a means for the energy matched MO to form a continuous equipotential energy surface. In the case that an independent MO is formed, the AO force balance causes the remaining electrons to be at lower energy and a smaller radius. In another case, the atomic orbital may hybridize in order to achieve a bond at an energy minimum, and the sharing of electrons between two or more such orbitals to form a MO permits the participating hybridized orbitals to decrease in energy through a decrease in the radius of one or more of the participating orbitals. Representative cases were solved. Specifically, the results of the determination of bond parameters of carbon dioxide $\left(\mathrm{CO}_{2}\right)$, nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$, ethane $\left(\mathrm{CH}_{3} \mathrm{CH}_{3}\right)$, ethylene $\left(\mathrm{CH}_{2} \mathrm{CH}_{2}\right)$, acetylene $(\mathrm{CHCH})$, benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$, propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$, butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$, pentane $\left(\mathrm{C}_{5} \mathrm{H}_{12}\right)$, hexane ( $\left.\mathrm{C}_{6} \mathrm{H}_{14}\right)$, heptane $\left(C_{7} H_{16}\right)$, octane $\left(C_{8} H_{18}\right)$, nonane $\left(C_{9} H_{20}\right)$, decane $\left(C_{10} H_{22}\right)$, undecane $\left(C_{11} H_{24}\right)$, dodecane $\left(C_{12} H_{26}\right)$, and octadecane $\left(C_{18} H_{38}\right)$ are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## CARBON DIOXIDE MOLECULE

The carbon dioxide molecule can be formed by the reaction of carbon monoxide and an oxygen atom:

$$
\begin{equation*}
\mathrm{CO}+\mathrm{O} \rightarrow \mathrm{CO}_{2} \tag{14.1}
\end{equation*}
$$

Each equivalent bond in the carbon dioxide molecule comprises a double bond that is energy-matched to the filled $C 2 s$ orbital. Each such bond comprises $75 \%$ of a $H_{2}$-type MO with four paired electrons as a basis set such that three electrons can be assigned to each $C=O$ bond. Thus, the two $C 2 p$ electrons combine with the four $O 2 p$ electrons, two from each $O$, as a linear combination to form the two $\mathrm{C}=\mathrm{O}$ bonds of $\mathrm{CO}_{2}$. The force balance equation and radius $r_{8}$ of the $2 p$ shell of $O$ is derived in the Eight-Electron Atoms section. With the formation of the $H_{2}$-type MOs by the contribution of two $2 p$ electrons from each of the two $O$ atoms, a factor of two increase of the central field on the remaining $O 2 p$ electrons arises. The resulting increased Coulombic as well as magnetic central forces decrease the radii of the $O 2 p$ shells such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of $\mathrm{CO}_{2}$ is $C 1 s^{2} O_{1} 1 s^{2} O_{2} 1 s^{2} C 2 s^{2} O_{1} 2 s^{2} O_{2} 2 s^{2} O_{1} 2 p^{2} O_{2} 2 p^{2} \sigma_{O_{2}, C, O_{1}}^{6}$ where the subscripts designate the $O$ atom, 1 or $2, \sigma$ designates the $H_{2}$ type MO, and the orbital arrangement is:

Carbon dioxide is predicted to be diamagnetic in agreement with observations [1].

## FORCE BALANCE OF THE $2 p$ SHELL OF THE OXYGEN ATOM OF THE CARBON DIOXIDE MOLECULE

For each $O$ atom, force balance for the outermost $2 p$ electron of $\mathrm{CO}_{2}$ (electron 6 ) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 6 and the other $2 p$ electrons as well as the $2 s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Eight-Electron Atoms section. The central Coulomb force on the outer-most $2 p$ shell electron of $C O$ (electron 6) due to the nucleus and the inner five electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{e l e}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}} \mathbf{i}_{\mathbf{r}} \tag{14.3}
\end{equation*}
$$

for $r>r_{5}$. The $2 p$ shell possess a +2 external electric field given by Eq. (10.92) for $r>r_{6}$. The energy is minimized with conservation of angular momentum. This condition is met when the diamagnetic force, $\mathbf{F}_{\text {diamagnetic }}$, of Eq. (10.82) due to the $p$ orbital contribution is given by:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic }}=-\left(\frac{2}{3}\right) \frac{\hbar^{2}}{4 m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}}=-\frac{2 \hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}} \mathbf{i}_{\mathbf{r}} \tag{14.4}
\end{equation*}
$$

where $s=1 / 2$. And, $\mathbf{F}_{\text {mag } 2}$ corresponding to the conserved spin and orbital angular momentum given by Eq. (10.157) is:

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 2}=\frac{1}{Z} \frac{2 \hbar^{2}}{m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathrm{r}} \tag{14.5}
\end{equation*}
$$

The electric field external to the $2 p$ shell given by Eq. (10.92) for $r>r_{6}$ gives rise to a second diamagnetic force, $\mathbf{F}_{\text {diamagnetic } 2}$, given by Eq. (10.93). $\mathbf{F}_{\text {diamagnetic } 2}$ due to the binding of the p-orbital electron having an electric field of +2 outside of its radius is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 2}=-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{m_{e} r_{6}^{4}} 10 \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{14.6}
\end{equation*}
$$

The radius of the $2 p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (14.3)) and diamagnetic (Eqs. (14.4) and (14.6)), and paramagnetic (Eq. (14.5)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{6}^{2}}{r_{6}}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}}-\frac{2 \hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)}+\frac{2 \hbar^{2}}{Z m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)}-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{6}^{4} m_{e}} 10 \sqrt{s(s+1)} \tag{14.7}
\end{equation*}
$$

Substitution of $v_{6}=\frac{\hbar}{m_{e} r_{6}}$ (Eq. (1.35)) and $s=\frac{1}{2}$ into Eq. (14.7) gives:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} r_{6}^{3}}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}}-\frac{2 \hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{2 \hbar^{2}}{Z m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}}-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{6}^{4} m_{e}} 10 \sqrt{\frac{3}{4}} \tag{14.8}
\end{equation*}
$$

The quadratic equation corresponding to Eq. (14.8) is:

$$
\begin{equation*}
r_{6}^{2}-\frac{\frac{\hbar^{2}}{m_{e}}}{\left(\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)^{2}} r_{6}-\frac{\frac{\hbar^{2}}{m_{e}}\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3} 10 \sqrt{\frac{3}{4}}}{\left(\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)}=0 \tag{14.9}
\end{equation*}
$$

The solution of Eq. (14.9) using the quadratic formula is:

$$
\begin{equation*}
r_{6}=\frac{a_{0}}{\left((Z-5)-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)} \pm a_{0} \sqrt{\left(\frac{1}{\left((Z-5)-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}\right)^{2}} \sqrt{\frac{20 \sqrt{3}\left(\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3}\right)}{\left((Z-5)-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}}, r_{3} \text { in units of } a_{0} \tag{14.10}
\end{equation*}
$$

The positive root of Eq. (14.10) must be taken in order that $r_{6}>0$. Substitution of $\frac{r_{3}}{a_{0}}=0.59020$ (Eq. (10.62) with $Z=8$ ) into Eq. (14.10) gives:

$$
\begin{equation*}
r_{6}=0.74776 a_{0} \tag{14.11}
\end{equation*}
$$

## ENERGIES OF THE $2 s$ AND $2 p$ SHELLS OF THE CARBON ATOM AND THE $2 p$ SHELL OF THE OXYGEN ATOMS OF THE CARBON DIOXIDE MOLECULE

Consider the determination of the total energy of $\mathrm{CO}_{2}$ from the reaction of a carbon atom with two oxygen atoms. With the formation of the $H_{2}$-type MO by the contribution of two $2 p$ electrons from the $C$ atom, the remaining outer-shell atomic electrons comprise the $2 s$ electrons which are unchanged by bonding with two oxygen atoms. However, the total energy of the $\mathrm{CO}_{2}$ molecule, which is subtracted from the sum of the energies of the oxygen atom and carbon monoxide molecule to determine the $O-C O$ bond energy, is increased by the ionization energies of $C, C^{+}, O$, and $2 O^{+}$given by Eqs. (14.12-14.15), respectively. Experimentally, the energies are [2]:

$$
\begin{align*}
& E(\text { ionization } ; C)=11.26030 \mathrm{eV}  \tag{14.12}\\
& E\left(\text { ionization } ; C^{+}\right)=24.38332 \mathrm{eV}  \tag{14.13}\\
& E(\text { ionization } ; O)=13.61806 \mathrm{eV}  \tag{14.14}\\
& E\left(\text { ionization } ; O^{+}\right)=35.11730 \mathrm{eV} \tag{14.15}
\end{align*}
$$

In addition, the central forces on the $2 p$ shell of the $O$ atom are increased with the formation of the $\sigma$ MO which reduces the shell's radius and increases its total energy. The Coulombic energy terms of the total energy of each $O$ atom at the new radius are calculated and added to the ionization energies of $C, C^{+}, O$, and $2 O^{+}$, and the energy of the $\sigma$ MO to give the total energy of $\mathrm{CO}_{2}$. Then, the bond energy is determined from the total $\mathrm{CO}_{2}$ energy.

The radius $r_{8}$ of each oxygen atom before bonding is given by Eq. (10.162):

$$
\begin{equation*}
r_{8}=a_{0} \tag{14.16}
\end{equation*}
$$

Using the initial radius $r_{8}$ of each $O$ atom and the final radius $r_{6}$ of the $O 2 p$ shell (Eq. (14.11)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_{T}(O, 2 p)$ of the Coulombic energy change of the $O 2 p$ electrons of each $O$ atom is determined using Eq. (10.102):

$$
\begin{equation*}
E_{T}(O, 2 p)=-\sum_{n=4}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{6}}-\frac{1}{r_{8}}\right)=-(13.60580 \mathrm{eV})(0.33733)(3+4)=-32.12759 \mathrm{eV} \tag{14.17}
\end{equation*}
$$

## FORCE BALANCE OF THE $\sigma$ MO OF THE CARBON DIOXIDE MOLECULE

As in the case of $\mathrm{H}_{2}$, the $\sigma \mathrm{MO}$ is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into the $C$ atom for distances shorter than the radius of the $C 2 s$ shell; nor, can it extend into the $O$ atom for distances shorter than the radius of the $O 2 p$ shell. Thus, the MO surface of each $C=O$ bond comprises a prolate spheroid that bridges and is continuous with the $2 s$ and $2 p$ shells of the $O$ and $C$ atoms whose nuclei serve as the foci. The energy of each prolate spheroid is matched to that of the $C 2 s$ and $O 2 p$ shells. As in the case of previous examples of energy-matched MOs such as $O H$ and NH , the $\mathrm{C}=\mathrm{O}$-bond MO must comprise $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO in order to match potential, kinetic, and orbital
energy relationships. However, the paired electrons of the $C 2 s$ and $O 2 p$ shells are not involved in bonding. Rather, the AOs permit a continuous surface comprising the two $C=O$-bond MOs having six paired electrons, two from each of the $C$ and the two $O$ atoms:

$$
\begin{equation*}
2\left(0.75 \mathrm{H}_{2} \mathrm{MO}\right) \rightarrow \mathrm{CO}_{2} \mathrm{MO} \tag{14.18}
\end{equation*}
$$

The force balance of the $\mathrm{CO}_{2} \mathrm{MO}$ is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.18) and the energy matching condition between the carbon and oxygen components of the MO.

Similar to the OH and $\mathrm{H}_{2} \mathrm{O}$ cases given by Eqs. (13.57) and (13.162), the $\mathrm{H}_{2}$-type ellipsoidal MO comprises $75 \%$ of the $\mathrm{CO}_{2} \mathrm{MO}$; so, the electron charge density in Eq. (11.65) is given by $-0.75 e$. Thus, $k^{\prime}$ of each $H_{2}$-type-ellipsoidal-MO component of the $\mathrm{CO}_{2} \mathrm{MO}$ is given by Eq. (13.59). The distance from the origin of each $C=O$-bond MO to each focus $c^{\prime}$ is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C=O$-bond MO $b=c$ given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). Then, the solution of the semimajor axis $a$ allows for the solution of the other axes of the prolate spheroidal and eccentricity of the $\mathrm{CO}_{2} \mathrm{MO}$.

The energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ of the $\mathrm{CO}_{2} \sigma$ MO are the same as those of OH given by Eqs. (13.67-13.73), except that the terms based on charge are multiplied by four and the kinetic energy term is multiplied by two due to each $\sigma$-MO double bond:

$$
\begin{equation*}
E_{T}(C=O, \sigma)=-\frac{4 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right] \tag{14.19}
\end{equation*}
$$

where $E_{T}(C=O, \sigma)$ is the total energy of each $C=O \quad \mathrm{MO}$ of $\mathrm{CO}_{2}$. The total energy of a $\mathrm{H}_{2}$-type ellipsoidal MO is given by Eqs. (11.212) and (13.75). A minimum energy is obtained when each double bond of the $\sigma \mathrm{MO}$ of $\mathrm{CO}_{2}$ comprises the energy equivalent of four $H_{2}$-type ellipsoidal MOs. For each $C=O$ bond to match the energy of the $C 2 s$ orbital, the ionization energy of $C$ and $C^{+}$(Eqs. (14.12-14.13)) must be added for each bond of the double bond. Thus, the total energy of each $C=O$-bond MOs is:

$$
\begin{align*}
E_{T}(C=O, \sigma) & =2\binom{2\left(-\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}\left[\left(2 \sqrt{2}-\sqrt{2}+\frac{\sqrt{2}}{2}\right) \ln \frac{\sqrt{2}+1}{\sqrt{2}-1}-\sqrt{2}\right]\right)}{\left.+ \text { E(ionization; } C)+ \text { E(ionization; } C^{+}\right)} \\
& =2(2(-31.63536831 \mathrm{eV})+11.26030 \mathrm{eV}+24.38332 \mathrm{eV})  \tag{14.20}\\
& =-55.25423 \mathrm{eV}
\end{align*}
$$

$E_{T}(C=O, \sigma)$ given by Eq. (14.19) is set equal to Eq. (14.20):

$$
\begin{equation*}
\frac{4 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[\left(\frac{3}{2}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]=e 55.25423 \mathrm{eV} \tag{14.21}
\end{equation*}
$$

From the energy relationship given by Eq. (14.21) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the $\mathrm{CO}_{2} \mathrm{MO}$ can be solved.

Substitution of Eq. (13.60) into Eq. (14.21) gives:

$$
\begin{equation*}
E_{T}(C=O, \sigma)=\frac{4 e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left[\left(\frac{3}{2}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right]=e 55.25423 \mathrm{eV} \tag{14.22}
\end{equation*}
$$

The most convenient way to solve Eq. (14.22) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is

$$
\begin{equation*}
a=1.80703 a_{0}=9.56239 \times 10^{-11} \mathrm{~m} \tag{14.23}
\end{equation*}
$$

Substitution of Eq. (14.23) into Eq. (13.60) is:

$$
\begin{equation*}
c^{\prime}=1.09758 a_{0}=5.80815 \times 10^{-11} \mathrm{~m} \tag{14.24}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.24) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.19516 a_{0}=1.16163 \times 10^{-10} \mathrm{~m} \tag{14.25}
\end{equation*}
$$

The experimental bond distance is [3]

$$
\begin{equation*}
2 c^{\prime}=1.1600 \times 10^{-10} \mathrm{~m} \tag{14.26}
\end{equation*}
$$

Substitution of Eqs. (14.23-14.24) into Eq. (13.62) is:

$$
\begin{equation*}
b=c=1.43550 a_{0}=7.59636 \times 10^{-11} \mathrm{~m} \tag{14.27}
\end{equation*}
$$

Substitution of Eqs. (14.23-14.24) into Eq. (13.63) is:

$$
\begin{equation*}
e=0.60740 \tag{14.28}
\end{equation*}
$$

The $C$ and $O$ nuclei comprise the foci of each $H_{2}$-type ellipsoidal MO defined as $O=C=O$. Consider the left-hand $C=O$ bond of the two equivalent bonds in the absence of the right-hand bond. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C 2 s \mathrm{AO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{4}=0.84317 a_{0}$ is the radius of the $C 2 s$ shell. Substitution of Eqs. (14.23-14.24) into Eq. (13.261) gives

$$
\begin{equation*}
\theta^{\prime}=54.53^{\circ} \tag{14.29}
\end{equation*}
$$

Then, the angle $\theta_{C 2 s A O}$ the radial vector of the $C 2 s \mathrm{AO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C 2 s A O}=180^{\circ}-54.53^{\circ}=125.47^{\circ} \tag{14.30}
\end{equation*}
$$

as shown in Figure 14.1. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{4} \sin \theta_{C 2 S A O}=0.84317 a_{0} \sin \theta_{C 2 s A O}=b \sin \theta_{H_{2} M O} \tag{14.31}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{H_{2} M O}=\sin ^{-1} \frac{0.84317 a_{0} \sin \theta_{C 2 s A O}}{b}=\sin ^{-1} \frac{0.84317 a_{0} \sin 125.47^{\circ}}{b} \tag{14.32}
\end{equation*}
$$

with the use of Eq. (14.30). Substitution of Eq. (14.27) into Eq. (14.32) gives:

$$
\begin{equation*}
\theta_{H_{2} M O}=28.58^{\circ} \tag{14.33}
\end{equation*}
$$

Then, the distance $d_{\mathrm{H}_{2} \mathrm{MO}}$ along the internuclear axis from the origin of $\mathrm{H}_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by

$$
\begin{equation*}
d_{\mathrm{H}_{2} \mathrm{MO}}=a \cos \theta_{\mathrm{H}_{2} \mathrm{MO}} \tag{14.34}
\end{equation*}
$$

Substitution of Eqs. (14.23) and (14.33) into Eq. (14.34) gives:

$$
\begin{equation*}
d_{H_{2} M O}=1.58687 a_{0}=8.39737 \times 10^{-11} \mathrm{~m} \tag{14.35}
\end{equation*}
$$

The distance $d_{C 2 s A O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by

$$
\begin{equation*}
d_{C 2 S A O}=d_{\mathrm{H}_{2} \mathrm{MO}}-c^{\prime} \tag{14.36}
\end{equation*}
$$

Substitution of Eqs. (14.24) and (14.35) into Eq. (14.36) gives:

$$
\begin{equation*}
d_{C 2 s A O}=0.48929 a_{0}=2.58922 \times 10^{-11} \mathrm{~m} \tag{14.37}
\end{equation*}
$$

The $C$ and $O$ nuclei comprise the foci of each $H_{2}$-type ellipsoidal MO defined as $O=C=O$. Consider the right-hand $C=O$ bond of the two equivalent bonds. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $O 2 p \mathrm{AO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{6}=0.74776 a_{0}$ is the radius of the $O 2 p$ shell. Substitution of Eqs. (14.23-14.24) into Eq. (13.261) gives

$$
\begin{equation*}
\theta^{\prime}=30.18^{\circ} \tag{14.38}
\end{equation*}
$$

Then, the angle $\theta_{O 2 p A O}$ the radial vector of the $O 2 p \mathrm{AO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{O 2 p A O}=180^{\circ}-30.18^{\circ}=149.82^{\circ} \tag{14.39}
\end{equation*}
$$

as shown in Figure 14.1. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{\mathrm{H}_{2} \mathrm{MO}}$ satisfies the following relationship:

$$
\begin{equation*}
r_{6} \sin \theta_{O 2 p A O}=0.74776 a_{0} \sin \theta_{O 2 p A O}=b \sin \theta_{H_{2} M O} \tag{14.40}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{H_{2} M O}=\sin ^{-1} \frac{0.74776 a_{0} \sin \theta_{O 2 p A O}}{b}=\sin ^{-1} \frac{0.74776 a_{0} \sin 149.82^{\circ}}{b} \tag{14.41}
\end{equation*}
$$

with the use of Eq. (14.39). Substitution of Eq. (14.27) into Eq. (14.41) gives:

$$
\begin{equation*}
\theta_{\mathrm{H}_{2} \mathrm{MO}}=15.18^{\circ} \tag{14.42}
\end{equation*}
$$

Then, the distance $d_{\mathrm{H}_{2} \mathrm{MO}}$ along the internuclear axis from the origin of $\mathrm{H}_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{\mathrm{H}_{2} \mathrm{MO}}=a \cos \theta_{\mathrm{H}_{2} \mathrm{MO}} \tag{14.43}
\end{equation*}
$$

Substitution of Eqs. (14.23) and (14.42) into Eq. (14.43) gives:

$$
\begin{equation*}
d_{H_{2} M O}=1.74396 a_{0}=9.22862 \times 10^{-11} \mathrm{~m} \tag{14.44}
\end{equation*}
$$

The distance $d_{O 2 p A O}$ along the internuclear axis from the origin of each $O$ atom to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{2 p A O}=d_{\mathrm{H}_{2} \mathrm{MO}}-c^{\prime} \tag{14.45}
\end{equation*}
$$

Substitution of Eqs. (14.24) and (14.44) into Eq. (14.45) gives:

$$
\begin{equation*}
d_{O 2 p A O}=0.64637 a_{0}=3.42047 \times 10^{-11} \mathrm{~m} \tag{14.46}
\end{equation*}
$$

As shown in Eq. (14.18), each $C=O$ bond comprises a factor of 0.75 of the charge-density of double that of the $H_{2}-$ type ellipsoidal MO. Using the electron configuration of $\mathrm{CO}_{2}$ (Eq. (14.2)), the radii of the $C 1 s=0.17113 a_{0}$ (Eq. (10.51)), $C 2 s=0.84317 a_{0}$ (Eq. (10.62)), $O 1 s=0.12739 a_{0}$ (Eq. (10.51)), $O 2 s=0.59020 a_{0}$ (Eq. (10.62)), and $O 2 p=0.74776 a_{0}$ (Eq. (14.11)) shells and the parameters of the $\sigma \mathrm{MO}$ of $\mathrm{CO}_{2}$ given by Eqs. (13.3-13.4), (14.23-14.25), and (14.27-14.28), the dimensional diagram and charge-density of the $\mathrm{CO}_{2} \mathrm{MO}$ are shown in Figures 14.1 and 14.2, respectively.

Figure 14.1. The cross section of the $\mathrm{CO}_{2} \mathrm{MO}$ showing the axes, $\sigma$ MO (two $\mathrm{H}_{2}$-type ellipsoidal MOs) with six paired electrons, with the $C 1 s$ and $2 s$ AOs and the $O 1 s, 2 s$, and $2 p$ AOs. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $r_{4}$ : radius of the $C 2 s$ shell having two paired electrons, $r_{6}$ : radius of the $O 2 p$ shell having two paired electrons.

Figure 14.2. $\mathrm{CO}_{2} \mathrm{MO}$ comprising the $\sigma \mathrm{MO}$ (two $\mathrm{H}_{2}$-type MOs) with $C$ and two $O$ atoms at the foci that have each donated two electrons to the $\sigma$ MO. Consequently, the outer electrons of the carbon atom comprise the $C 2 s$ shell, and each $\mathrm{O} 2 p$ shell has a smaller radius and a higher binding energy. (A) Color scale, translucent view of the charge-density of the $\mathrm{CO}_{2}$ MO. (B) Off-center cut-away view showing each complete inner most $O 1 s$ shell, and moving radially, the $O 2 s$ shell, the $O 2 p$ shell, and the $\sigma$ prolate spheroidal MO that has the corresponding $O$ atom as a focus. Moving radially from the carbon-atom focus, the complete inner most $C 1 s$ shell, the $C 2 s$ shell, and the $\sigma$ prolate spheroidal MOs are shown.

## SUM OF THE ENERGIES OF THE $\sigma$ MO AND THE AOS OF THE CARBON DIOXIDE MOLECULE

The energies of the $\mathrm{CO}_{2} \sigma \mathrm{MO}$ are given by the substitution of the semiprincipal axes (Eqs. (14.23-14.24) and (14.27)) into the energy equations of $O H$ (Eqs. (13.67-13.73)), except that the terms based on charge are multiplied by four and the kinetic energy term is multiplied by two due to each $\sigma$-MO double bond:

$$
\begin{align*}
& V_{e}=2^{2}\left(\frac{3}{4}\right) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-104.83940 \mathrm{eV}  \tag{14.47}\\
& V_{p}=2^{2} \frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=49.58464 \mathrm{eV}  \tag{14.48}\\
& T=2\left(\frac{3}{4}\right) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=14.50438 \mathrm{eV}  \tag{14.49}\\
& V_{m}=2^{2}\left(\frac{3}{4}\right) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-14.50438 \mathrm{eV}  \tag{14.50}\\
& E_{T}=V_{e}+T+V_{m}+V_{p} \tag{14.51}
\end{align*}
$$

Substitution of Eqs. (13.60) and (14.47-14.50) into Eq. (14.51) gives:

$$
\begin{equation*}
E_{T}(C=O, \sigma)=V_{e}+T+V_{m}+V_{p}=\frac{-4 e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left[\left(\frac{3}{2}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right]=-55.25476 \mathrm{eV} \tag{14.52}
\end{equation*}
$$

where $E_{T}(C=O, \sigma)$ is the total energy of each $C=O \quad \sigma$ MO of $C O_{2}$ given by Eq. (14.19) which is reiteratively matched to Eq. (14.20) within five-significant-figure round off error.

The total energy of $\mathrm{CO}_{2}, E_{T}\left(\mathrm{CO}_{2}\right)$, is given by the sum of $E$ (ionization; C ) and $E$ (ionization; $\mathrm{C}^{+}$), the sum of the energies of the first and second electrons of carbon (Eqs. (14.12-14.13)) donated to each double bond, the sum of E(ionization; $O$ ) and two times E(ionization; $O^{+}$), the energies of the first and second electrons of oxygen (Eqs. (14.14-14.15)) donated to the double bonds, two times $E_{T}(O, 2 p)$, the $O 2 p$ AO contribution due to the decrease in radius with the formation of each bond (Eq. (14.17)), and two times $E_{T}(C=O, \sigma)$, the $\sigma$ MO contribution given by Eq. (14.22):

$$
\begin{align*}
E_{T}\left(\mathrm{CO}_{2}\right) & =\binom{\text { E(ionization; } \left.C)+ \text { E(ionization; } C^{+}\right)+ \text {E(ionization; } O \text { ) }}{+2 E\left(\text { ionization; } O^{+}\right)+2 E_{T}(O, 2 p)+2 E_{T}(C=O, \sigma)} \\
& =\left(\begin{array}{l}
11.26030 \mathrm{eV}+24.38332 \mathrm{eV}+13.61806 \mathrm{eV} \\
+2(35.11730 \mathrm{eV})+2(-32.12759 \mathrm{eV}) \\
-2\left(\frac{4 e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left(\begin{array}{l}
\left(\frac{3}{2}\right) \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{\ln }-\sqrt{\frac{2 a a_{0}}{3}}
\end{array}\right)\right.
\end{array}\right)  \tag{14.53}\\
& =\binom{11.26030 \mathrm{eV}+24.38332 \mathrm{eV}+13.61806 \mathrm{eV}}{+2(35.11730 \mathrm{eV})+2(-32.12759 \mathrm{eV})-2(55.25423 \mathrm{eV})}=-55.26841 \mathrm{eV}
\end{align*}
$$

## VIBRATION OF $\mathrm{CO}_{2}$

The vibrational energy levels of $\mathrm{CO}_{2}$ may be solved by determining the Morse potential curve from the energy relationships for the transition from a $C$ atom and two $O$ atoms whose parameters are given by Eqs. (10.115-10.123) and (10.154-10.163), respectively, to a $C$ atom whose parameter $r_{4}$ is given by Eq. (10.61), two $O$ atoms whose parameter $r_{6}$ is given by Eq. (14.11), and the $\sigma \mathrm{CO}_{2} \mathrm{MO}$ whose parameters are given by Eqs. (14.23-14.25) and (14.27-14.28). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K\&P) [4] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

## THE DOPPLER ENERGY TERMS OF THE CARBON DIOXIDE MOLECULE

The equations of the radiation reaction force of carbon dioxide are the same as those of OH with the substitution of the $\mathrm{CO}_{2}$ parameters except that there is a factor of four increase in the central force in Eq. (13.140) due to the double bond. Using Eqs. (13.140-13.142), the angular frequency of the reentrant oscillation in the transition state is

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{4(0.75) e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=4.16331 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{14.54}
\end{equation*}
$$

where $b$ is given by Eq. (14.27). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 4.16331 \times 10^{16} \mathrm{rad} / \mathrm{s}=27.40365 \mathrm{eV} \tag{14.55}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(C O_{2}\right) / 2$ for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.55) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h v} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-27.63421 \mathrm{eV} \sqrt{\frac{2 e(27.40365 \mathrm{eV})}{m_{e} c^{2}}}=-0.28619 \mathrm{eV} \tag{14.56}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The transition state comprises $O--C O$, oxygen binding to $C O$. Vibration of the linear XYZ-molecular transition state corresponds to $v_{3}$ [5] with the maximum kinetic energy localized to the nascent $C-O$ bond. In this case, the kinetic energy of the nuclei is the maximum for this bond. Thus, $\bar{E}_{\text {Kvib }}$ is the vibrational energy. The decrease in the energy of the $\mathrm{CO}_{2}$ MO due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.56) and $\bar{E}_{\text {Kvib }}$, the vibrational energy. Using the experimental $\mathrm{CO}_{2} E_{\text {vib }}\left(v_{3}\right)$ of $2349 \mathrm{~cm}^{-1}(0.29124 \mathrm{eV})$ [6] for $\bar{E}_{K v i b}$ of the transition state, $\bar{E}_{\text {osc }}\left(\mathrm{CO}_{2}\right)$ is:

$$
\begin{align*}
& \bar{E}_{o s c}\left(C O_{2}\right)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+E_{v i b}  \tag{14.57}\\
& \bar{E}_{\text {osc }}\left(C O_{2}\right)=-0.28619 \mathrm{eV}+0.29124 \mathrm{eV}=0.00505 \mathrm{eV} \tag{14.58}
\end{align*}
$$

## TOTAL AND BOND ENERGIES OF THE CARBON DIOXIDE MOLECULE

$E_{T+\text { osc }}\left(\mathrm{CO}_{2}\right)$, the total energy of $\mathrm{CO}_{2}$ including the Doppler term, is given by the sum of $E_{T}\left(\mathrm{CO}_{2}\right)$ (Eq. (14.53)) and $\bar{E}_{\text {osc }}\left(\mathrm{CO}_{2}\right)$ given by Eq. (14.58).

$$
\begin{align*}
& E_{T+o s c}\left(\mathrm{CO}_{2}\right)=\left(\begin{array}{l}
2\left(V_{e}+T+V_{m}+V_{p}\right)+E(\text { ionization } ; C) \\
+E\left(\text { ionization } ; C^{+}\right)+E(\text { ionization } ; O)+2 E\left(\text { ionization; } O^{+}\right) \\
+2 E_{T}(O, 2 p)+\bar{E}_{o s c}\left(\mathrm{CO}_{2}\right)
\end{array}\right) \\
& =\left(\begin{array}{l}
2 E_{T}(C=O, \sigma)+E(\text { ionization } ; C)+E\left(\text { ionization; } C^{+}\right) \\
+E(\text { ionization; } O)+2 E\left(\text { ionization; } O^{+}\right) \\
+2 E_{T}(\mathrm{O}, 2 p)+\bar{E}_{\text {osc }}\left(\mathrm{CO}_{2}\right)
\end{array}\right)  \tag{14.59}\\
& =E_{T}\left(\mathrm{CO}_{2}\right)+\bar{E}_{\text {osc }}\left(\mathrm{CO}_{2}\right) \\
& E_{T+o s c}\left(C O_{2}\right)=\left\{\begin{array}{l}
\left(\begin{array}{l}
\left.\left.\left(\begin{array}{l}
2\left(\frac{-4 e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left(\frac{3}{2}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right.
\end{array}\right)\right)+ \text { E(ionization; } C\right) \\
\left.+ \text { E(ionization; } C^{+}\right)+E(\text { ionization } ; O) \\
+2 E\left(\text { ionization } ; O^{+}\right)-2 \sum_{O, n=4}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{6}}-\frac{1}{r_{8}}\right)
\end{array}\right) \\
\left(\begin{array}{l}
\frac{1+\frac{4(0.75) e^{2}}{2}}{\frac{4 \pi \varepsilon_{0} b^{3}}{m_{e}}}
\end{array}\right)+E_{v i b}^{m_{e} c^{2}}
\end{array}\right)  \tag{14.60}\\
& =-55.26841 \mathrm{eV}-0.28619 \mathrm{eV}+E_{v i b}
\end{align*}
$$

From Eqs. (14.57-14.60), the total energy of the $\mathrm{CO}_{2} \mathrm{MO}$ is:

$$
\begin{equation*}
E_{T+o s c}\left(C O_{2}\right)=-55.25476 \mathrm{eV}+\bar{E}_{\text {osc }}\left(\mathrm{CO}_{2}\right)=-55.25476 \mathrm{eV}+0.00505 \mathrm{eV}=-55.26336 \mathrm{eV} \tag{14.61}
\end{equation*}
$$

where the experimental $E_{v i b}$ was used.
As in the case of the dissociation of the bond of the hydroxyl radical, an oxygen atom is formed with dissociation of $\mathrm{CO}_{2}$. O has two unpaired electrons as shown in Eq. (13.55) which interact to stabilize the atom as shown by Eq. (10.16110.162). The lowering of the energy of the reactants decreases the bond energy. Thus, the total energy of oxygen is reduced by the energy in the field of the two magnetic dipoles given by Eq. (7.46) and Eq. (13.101).

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} a_{0}^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{a_{0}^{3}}=0.11441 \mathrm{eV} \tag{14.62}
\end{equation*}
$$

The $\mathrm{CO}_{2}$ bond dissociation energy, $E_{D}\left(\mathrm{CO}_{2}\right)$, is given by the sum of the energies of the $C O$ and the $O$ atom minus the sum of $E_{T+o s c}\left(\mathrm{CO}_{2}\right)$ and $E$ (magnetic) :

$$
\begin{equation*}
E_{D}\left(\mathrm{CO}_{2}\right)=E(\mathrm{CO})+E(\mathrm{O})-\left(E(\text { magnetic })+E_{T+\text { osc }}\left(\mathrm{CO}_{2}\right)\right) \tag{14.63}
\end{equation*}
$$

The energy of an oxygen atom is given by Eq. (14.14) and $E_{T}(C O)$ is given by the sum of the experimental energies of $C$ (Eq. (14.12)), $O$ (Eq. (14.14)), and the negative of the bond energy of $C O$ (Eq. (13.914)):

$$
\begin{equation*}
E(C O)=-11.26030 \mathrm{eV}-13.618060 \mathrm{eV}-11.15696 \mathrm{eV}=-36.03532 \mathrm{eV} \tag{14.64}
\end{equation*}
$$

The energy of $O$ is given by the negative of the corresponding ionization energy given in Eq. (4.14). Thus, the $\mathrm{CO}_{2}$ bond dissociation energy, $E_{D}\left(\mathrm{CO}_{2}\right)$, given by the Eqs. (4.14) and (14.61-14.64) is:

$$
\begin{align*}
E_{D}\left(C O_{2}\right) & =-(36.03532 \mathrm{eV}+13.618060 \mathrm{eV})-\left(E(\text { magnetic })+E_{T+o s c}\left(C O_{2}\right)\right) \\
& =-49.65338 \mathrm{eV}-(0.11441 \mathrm{eV}-55.26336 \mathrm{eV})  \tag{14.65}\\
& =5.49557 \mathrm{eV}
\end{align*}
$$

The experimental $\mathrm{CO}_{2}$ bond dissociation energy is [7]:

$$
\begin{equation*}
E_{D 298}\left(\mathrm{CO}_{2}\right)=5.516 \mathrm{eV} \tag{14.66}
\end{equation*}
$$

The results of the determination of bond parameters of $\mathrm{CO}_{2}$ are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## NITROGEN DIOXIDE MOLECULE

The nitrogen dioxide molecule can be formed by the reaction of nitric oxide and an oxygen atom:

$$
\begin{equation*}
\mathrm{NO}+\mathrm{O} \rightarrow \mathrm{NO}_{2} \tag{14.67}
\end{equation*}
$$

The bonding in the nitrogen dioxide molecule comprises two double bonds, each a $H_{2}$-type MO with four paired electrons wherein the central $N$ atom is shared by both bonds such that six electrons can be assigned to the two $N=O$ bonds. Thus, two $N 2 p$ electrons combine with the four $O 2 p$ electrons, two from each $O$, as a linear combination to form the two overlapping $N=O$ bonds of $N O_{2}$. The force balance equation and radius $r_{7}$ of the $2 p$ shell of $N$ is derived in the Seven-Electron Atoms section. The force balance equation and radius $r_{8}$ of the $2 p$ shell of $O$ is derived in the Eight-Electron Atoms section. With the formation of each of the two $H_{2}$-type MOs by the contribution of two $2 p$ electrons each from the $N$ and $O$ atoms, a diamagnetic force arises between the remaining outer shell atomic electrons, the $2 s$ and $2 p$ electrons of N and O , and the $\mathrm{H}_{2}-$ type MO. This force from $N$ and O causes the $\mathrm{H}_{2}$-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the factor of two increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining $N$ and $O$ electrons decrease the radii of the corresponding shells such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of $\mathrm{NO}_{2}$ is $N 1 s^{2} O_{1} 1 s^{2} O_{2} 1 s^{2} N 2 s^{2} O_{1} 2 s^{2} O_{2} 2 s^{2} N 2 p^{1} O_{1} 2 p^{2} O_{2} 2 p^{2} \sigma_{O_{2}, N, O_{1}}^{6}$ where the subscripts designate the $O$ atom, 1 or 2 , $\sigma$ designates the $H_{2}$-type MO , and the orbital arrangement is:

Nitrogen dioxide is predicted to be weakly paramagnetic in agreement with observations [1].

## FORCE BALANCE OF THE $2 p$ SHELL OF THE NITROGEN ATOM OF NITROGEN DIOXIDE

For the $N$ atom, force balance for the outermost $2 p$ electron of $\mathrm{NO}_{2}$ (electron 5) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 5 and the $2 s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Seven-Electron Atoms section. The central Coulomb force on the outer-most $2 p$ shell electron of $N O$ (electron 5) due to the nucleus and the inner four electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{\text {ele }}=\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0} r_{5}^{2}} \mathbf{i}_{\mathrm{r}} \tag{14.69}
\end{equation*}
$$

for $r>r_{4}$. The $2 p$ shell possess a +2 external electric field given by Eq. (10.92) for $r>r_{5}$. The energy is minimized with conservation of angular momentum. This condition is met when the magnetic forces of N in $\mathrm{NO}_{2}$ are the same as those of N in $N O$. They are also the same as those of $N$ in the nitrogen molecule with $r_{5}$ replacing $r_{6}$ and with an increase of the central field by an integer. The diamagnetic force, $\mathbf{F}_{\text {diamagnetic }}$, of Eq. (10.82) due to the $p$-orbital contribution is given by Eq. (13.918).

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic }}=-\left(\frac{1}{3}\right) \frac{\hbar^{2}}{4 m_{e} r_{5}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}}=-\frac{\hbar^{2}}{12 m_{e} r_{5}^{2} r_{3}} \sqrt{\frac{3}{4}} \mathbf{i}_{\mathbf{r}} \tag{14.70}
\end{equation*}
$$

And, $\mathbf{F}_{\text {mag } 2}$ corresponding to the conserved orbital angular momentum of the three orbitals is also the same as that of $\mathrm{NO}_{2}$ given by Eq. (13.919):

$$
\begin{equation*}
\mathbf{F}_{\operatorname{mag} 2}=\frac{1}{Z} \frac{3 \hbar^{2}}{m_{e} r_{5}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathrm{r}} \tag{14.71}
\end{equation*}
$$

The electric field external to the $2 p$ shell given by Eq. (10.92) for $r>r_{5}$ gives rise to a second diamagnetic force, $\mathbf{F}_{\text {diamagnetic 2 }}$, given by Eq. (10.93). $\mathbf{F}_{\text {diamagnetic } 2}$ due to the binding of the p-orbital electron having an electric field of +2 outside of its radius is given by Eq. (13.920):

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 2}=-\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{m_{e} r_{5}^{4}} 10 \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{14.72}
\end{equation*}
$$

The radius of the $2 p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (14.69)) and diamagnetic (Eqs. (14.70) and (14.72)), and paramagnetic (Eq. (14.71)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{5}^{2}}{r_{5}}=\binom{\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0} r_{5}^{2}}-\frac{\hbar^{2}}{12 m_{e} r_{5}^{2} r_{3}} \sqrt{s(s+1)}+\frac{3 \hbar^{2}}{Z m_{e} r_{5}^{2} r_{3}} \sqrt{s(s+1)}}{-\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{5}^{4} m_{e}} 10 \sqrt{s(s+1)}} \tag{14.73}
\end{equation*}
$$

Substitution of $v_{5}=\frac{\hbar}{m_{e} r_{5}}$ (Eq. (1.35)) and $s=\frac{1}{2}$ into Eq. (14.73) gives:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} r_{5}^{3}}=\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0} r_{5}^{2}}-\frac{\hbar^{2}}{12 m_{e} r_{5}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{3 \hbar^{2}}{Z m_{e} r_{5}^{2} r_{3}} \sqrt{\frac{3}{4}}-\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{5}^{4} m_{e}} 10 \sqrt{\frac{3}{4}} \tag{14.74}
\end{equation*}
$$

The quadratic equation corresponding to Eq. (14.74) is:

$$
\begin{equation*}
r_{5}^{2}-\frac{\frac{\hbar^{2}}{m_{e}}}{\left(\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)} r_{5}-\frac{\frac{\hbar^{2}}{m_{e}}\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3} 10 \sqrt{\frac{3}{4}}}{\left(\frac{(Z-4) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)}=0 \tag{14.75}
\end{equation*}
$$

The solution of Eq. (14.75) using the quadratic formula is:

$$
=\frac{a_{0}}{\left((Z-4)-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)} \pm a_{0} \sqrt{\left(\frac{\left((Z-4)-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}{}\right)^{2}} \sqrt{\left(\frac{20 \sqrt{3}\left(\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3}\right)}{\left((Z-4)-\left(\frac{1}{12}-\frac{3}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}\right.}, r_{3} \text { in units of } a_{0}
$$

The positive root of Eq. (14.76) must be taken in order that $r_{5}>0$. Substitution of $\frac{r_{3}}{a_{0}}=0.69385$ (Eq. (10.62) with $Z=7$ ) into Eq. (14.76) gives:

$$
\begin{equation*}
r_{5}=0.74841 a_{0} \tag{14.77}
\end{equation*}
$$

## FORCE BALANCE OF THE $2 p$ SHELL OF EACH OXYGEN ATOM OF NITROGEN DIOXIDE

For each $O$ atom, force balance for the outermost $2 p$ electron of $\mathrm{NO}_{2}$ (electron 6) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 6 and the other $2 p$ electron as well as the $2 s$ shell electrons due to spin and orbital angular momentum. The forces used are derived in the Eight-Electron Atoms section. The central Coulomb force on the outer-most $2 p$ shell electron of $\mathrm{NO}_{2}$ (electron 6) due to the nucleus and the inner five electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$
\begin{equation*}
\mathbf{F}_{e l e}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}} \mathbf{i}_{\mathbf{r}} \tag{14.78}
\end{equation*}
$$

for $r>r_{5}$. The $2 p$ shell possess an external electric field of +2 given by Eq. (10.92) for $r>r_{6}$. The energy is minimized with conservation of angular momentum. This condition is met when the magnetic forces of $O$ in $N O_{2}$ are the same as those of $O$ in $N O$. The diamagnetic force, $\mathbf{F}_{\text {diamagnetic }}$, of Eq. (10.82) due to the $p$-orbital contribution given by Eq. (13.927) is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic }}=-\left(\frac{2}{3}\right) \frac{\hbar^{2}}{4 m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}}=-\frac{2 \hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}} \mathbf{i}_{\mathbf{r}} \tag{14.79}
\end{equation*}
$$

And, $\mathbf{F}_{\text {mag } 2}$ corresponding to the conserved spin and orbital angular momentum given by Eq. (13.928) is:

$$
\begin{equation*}
\mathbf{F}_{m a g} 2=\frac{1}{Z} \frac{2 \hbar^{2}}{m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{14.80}
\end{equation*}
$$

The electric field external to the $2 p$ shell given by Eq. (10.92) for $r>r_{6}$ gives rise to a second diamagnetic force, $\mathbf{F}_{\text {diamagnetic 2 }}$, given by Eq. (10.93). $\mathbf{F}_{\text {diamagnetic } 2}$ due to the binding of the p-orbital electron having an electric field of +2 outside of its radius given by Eq. (13.929) is:

$$
\begin{equation*}
\mathbf{F}_{\text {diamagnetic } 2}=-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{m_{e} r_{6}^{4}} 10 \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{14.81}
\end{equation*}
$$

In addition, the contribution of two $2 p$ electrons in the formation of the $\sigma$ MO gives rise to a paramagnetic force on the remaining paired $2 p$ electrons. The force $\mathbf{F}_{\text {mag } 3}$ is given by Eq. (13.930) is:

$$
\begin{equation*}
\mathbf{F}_{\text {mag } 3}=\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{s(s+1)} \mathbf{i}_{\mathbf{r}} \tag{14.82}
\end{equation*}
$$

The radius of the $2 p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (14.78)) and diamagnetic (Eqs. (14.79) and (14.81)), and paramagnetic (Eqs. (14.80) and (14.82)) forces as follows:

$$
\begin{equation*}
\frac{m_{e} v_{6}^{2}}{r_{6}}=\binom{\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}}-\frac{2 \hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)}+\frac{2 \hbar^{2}}{Z m_{e} r_{6}^{2} r_{3}} \sqrt{s(s+1)}}{-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{6}^{4} m_{e}} 10 \sqrt{s(s+1)}+\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{s(s+1)}} \tag{14.83}
\end{equation*}
$$

Substitution of $v_{6}=\frac{\hbar}{m_{e} r_{6}}$ (Eq. (1.35)) and $s=\frac{1}{2}$ into Eq. (14.83) gives:

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} r_{6}^{3}}-\frac{\hbar^{2}}{4 m_{e} r_{6}^{3}} \sqrt{\frac{3}{4}}=\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0} r_{6}^{2}}-\frac{2 \hbar^{2}}{12 m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}}+\frac{2 \hbar^{2}}{Z m_{e} r_{6}^{2} r_{3}} \sqrt{\frac{3}{4}}-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) \frac{r_{3} \hbar^{2}}{r_{6}^{4} m_{e}} 10 \sqrt{\frac{3}{4}} \tag{14.84}
\end{equation*}
$$

The quadratic equation corresponding to Eq. (14.84) is:

$$
\begin{equation*}
r_{6}^{2}-\frac{\frac{\hbar^{2}}{m_{e}}\left(1-\frac{\sqrt{3}}{8}\right)}{\left(\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)^{-}} r_{6}-\frac{\frac{\hbar^{2}}{m_{e}}\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3} 10 \sqrt{\frac{3}{4}}}{\left(\frac{(Z-5) e^{2}}{4 \pi \varepsilon_{0}}-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\hbar^{2}}{m_{e} r_{3}} \sqrt{\frac{3}{4}}\right)}=0 \tag{14.85}
\end{equation*}
$$

The solution of Eq. (14.85) using the quadratic formula is:

$$
r_{6}=\frac{a_{0}\left(1-\frac{\sqrt{3}}{8}\right)}{\left((Z-5)-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)} \pm a_{0} \sqrt{\left(\frac{1-\frac{\sqrt{3}}{8}}{\left(\frac{\left.(Z-5)-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}{\left(\frac{20 \sqrt{3}\left(\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right) r_{3}\right)}{\left((Z-5)-\left(\frac{2}{12}-\frac{2}{Z}\right) \frac{\sqrt{3}}{2 r_{3}}\right)}\right.}\right.}, r_{3} \text { in units of } a_{0}\right.}
$$

The positive root of Eq. (14.86) must be taken in order that $r_{6}>0$. Substitution of $\frac{r_{3}}{a_{0}}=0.59020$ (Eq. (10.62) with $Z=8$ ) into Eq. (14.86) gives:

$$
\begin{equation*}
r_{6}=0.70460 a_{0} \tag{14.87}
\end{equation*}
$$

## ENERGIES OF THE $2 p$ SHELLS OF THE NITROGEN ATOM AND OXYGEN ATOMS OF NITROGEN DIOXIDE

Consider the determination of the total energy of $\mathrm{NO}_{2}$ from the reaction of a nitrogen atom with two oxygen atoms. With the formation of each $\mathrm{H}_{2}$-type MO by the contribution of two $2 p$ electrons from each of the $N$ and the two $O$ atoms, the total energy of the $\mathrm{NO}_{2}$ molecule, which is subtracted from the sum of the energies of the nitrogen and oxygen atoms to determine the bond energy, is increased by the ionization energies of $N, N^{+}, O$, and $2 O^{+}$given by Eqs. (14.88-14.91), respectively. Experimentally, the energies are [2]:

$$
\begin{align*}
& E(\text { ionization; } N)=14.53414 \mathrm{eV}  \tag{14.88}\\
& E\left(\text { ionization; } N^{+}\right)=29.6013 \mathrm{eV}  \tag{14.89}\\
& E(\text { ionization; } O)=13.61806 \mathrm{eV}  \tag{14.90}\\
& E\left(\text { ionization } ; O^{+}\right)=35.11730 \mathrm{eV} \tag{14.91}
\end{align*}
$$

In addition, the central forces on the $2 p$ shells of the $N$ and $O$ atoms are increased with the formation of the $\sigma$ MOs which reduces each shell's radius and increases its total energy. The change per bond is the same as that of NO since the final radii given by Eq. (14.77) and (14.87) are the same for $N O$ and $\mathrm{NO}_{2}$. The Coulombic energy terms of the total energy of the N and $O$ atoms at the new radii are calculated and added to the ionization energies of $N, N^{+}, O$, and $2 O^{+}$, and the energy of the
$\sigma$ MOs to give the total energy of $\mathrm{NO}_{2}$. Then, the bond energy is determined from the total $\mathrm{NO}_{2}$ energy.
The radius $r_{7}$ of the nitrogen atom before bonding is given by Eq. (10.142).

$$
\begin{equation*}
r_{7}=0.93084 a_{0} \tag{14.92}
\end{equation*}
$$

Using the initial radius $r_{7}$ of the $N$ atom and the final radius $r_{5}$ of the $N 2 p$ shell (Eq. (14.77)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_{T}(N, 2 p)$ of the Coulombic energy change of the $N 2 p$ electrons of the $N$ atom is determined using Eq. (10.102):

$$
\begin{equation*}
E_{T}(N, 2 p)=-\sum_{n=4}^{4} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{5}}-\frac{1}{r_{7}}\right)=-(13.60580 \mathrm{eV})(0.26186)(3)=-10.68853 \mathrm{eV} \tag{14.93}
\end{equation*}
$$

The radius $r_{8}$ of the oxygen atom before bonding is given by Eq. (10.162).

$$
\begin{equation*}
r_{8}=a_{0} \tag{14.94}
\end{equation*}
$$

Using the initial radius $r_{8}$ of the $O$ atom and the final radius $r_{6}$ of the $O 2 p$ shell (Eq. (14.87)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_{T}(O, 2 p)$ of the Coulombic energy change of the $O 2 p$ electrons of the $O$ atom is determined using Eq. (10.102).

$$
\begin{equation*}
E_{T}(O, 2 p)=\sum_{n=4}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}}\left(\frac{1}{r_{6}}-\frac{1}{r_{8}}\right)=(13.60580 \mathrm{eV})\left(0.41925 a_{0}^{-1}\right)(3+4)=-39.92918 \mathrm{eV} \tag{14.95}
\end{equation*}
$$

## FORCE BALANCE OF THE $\sigma$ MO OF NITROGEN DIOXIDE

The force balance can be considered due to a second pair of two electrons binding to a molecular ion having $+2 e$ at each focus and a first bound pair. Then, the forces are the same as those of a molecule ion having $+e$ at each focus. The diamagnetic force $\mathbf{F}_{\text {diamagneticMO1 }}$ for each $\sigma-\mathrm{MO}$ of the $\mathrm{NO}_{2}$ molecule due to the two, paired electrons in the $O 2 p$ shell is given by Eq. (13.633) with $n_{e}=2$ :

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO1 }}=\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{14.96}
\end{equation*}
$$

This is also the corresponding force of $N O$ given by Eq. (13.942). $\mathbf{F}_{\text {diamagneticMO2 }}$ of the nitrogen dioxide molecule comprising nitrogen with charge $Z_{1}=7$ and $\left|L_{1}\right|=\hbar$ and $\left|L_{2}\right|=\sqrt{\frac{3}{4}} \hbar$ and the two oxygen atoms, each with $Z_{2}=8$ and $\left|L_{3}\right|=\hbar$ is given by the corresponding sum of the contributions. Using Eq. (13.835), $\mathbf{F}_{\text {diamagnetic } \mathrm{MO}_{2} \text { for } \mathrm{NO}_{2} \text { is: }}$

$$
\begin{equation*}
\mathbf{F}_{\text {diamagneticMO2 }}=\left(\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{2}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \mathbf{i}_{\xi} \tag{14.97}
\end{equation*}
$$

This is also the corresponding force of $N O$ given by Eq. (13.943) except the term due to oxygen is twice that of $N O$ due to the two oxygen atoms of $\mathrm{NO}_{2}$. The general force balance equation for the $\sigma-\mathrm{MO}$ of the nitrogen dioxide molecule given by Eqs. (11.200), and (14.97-14.98) is also the same as that of $C N$ (Eq. (14.836)) except for the doubling of the $\frac{2}{Z_{2}}$ term due to the two oxygen atoms:

$$
\begin{align*}
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D-\left(1+\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{2}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{14.98}\\
& \frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D-\left(\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{2}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D  \tag{14.99}\\
& \left(2+\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{2}{Z_{2}}\right) \frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{0} a b^{2}} D \tag{14.100}
\end{align*}
$$

$$
\begin{equation*}
a=\left(2+\frac{1}{Z_{1}}+\frac{\sqrt{\frac{3}{4}}}{Z_{1}}+\frac{2}{Z_{2}}\right) a_{0} \tag{14.101}
\end{equation*}
$$

Substitution of $Z_{1}=7$ and $Z_{2}=8$ into Eq. (14.101) gives:

$$
\begin{equation*}
a=2.51658 a_{0}=1.33171 \times 10^{-10} \mathrm{~m} \tag{14.102}
\end{equation*}
$$

Substitution of Eq. (14.102) into Eq. (11.79) is:

$$
\begin{equation*}
c^{\prime}=1.12173 a_{0}=5.93596 \times 10^{-11} \mathrm{~m} \tag{14.103}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.103) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.24347 a_{0}=1.18719 \times 10^{-10} \mathrm{~m} \tag{14.104}
\end{equation*}
$$

The experimental bond distance is [3]:

$$
\begin{equation*}
2 c^{\prime}=1.193 \times 10^{-10} \mathrm{~m} \tag{14.105}
\end{equation*}
$$

Substitution of Eqs. (14.102-14.103) into Eq. (11.80) is:

$$
\begin{equation*}
b=c=2.25275 a_{0}=1.19210 \times 10^{-10} \mathrm{~m} \tag{14.106}
\end{equation*}
$$

Substitution of Eqs. (14.102-14.103) into Eq. (11.67) is:

$$
\begin{equation*}
e=0.44574 \tag{14.107}
\end{equation*}
$$

The bonding in the nitrogen dioxide molecule comprises two double bonds, each a $H_{2}$-type MO with four paired electrons wherein the central $N$ atom is shared by both bonds such that six electrons can be assigned to the two $N=O$ bonds. Thus, two $N 2 p$ electrons combine with the four $O 2 p$ electrons, two from each $O$, as a linear combination to form the two overlapping $\mathrm{N}=\mathrm{O}$ bonds of $\mathrm{NO}_{2}$. Using the electron configuration of $\mathrm{NO}_{2}$ (Eq. (14.68)), the radii of the $N 1 s=0.14605 a_{0}$ (Eq. (10.51)), $\quad N 2 s=0.69385 a_{0} \quad$ (Eq. (10.62)), $\quad N 2 p=0.74841 a_{0} \quad$ (Eq. (14.77)), $O 1 s=0.12739 a_{0} \quad$ (Eq. (10.51)), $O 2 s=0.59020 a_{0}$ (Eq. (10.62)), and $O 2 p=0.70460 a_{0}$ (Eq. (14.87)) shells and the parameters of the $\sigma$ MOs of $\mathrm{NO}_{2}$ given by Eqs. (13.3-13.4), (14.102-14.104), and (14.106-14.107), the dimensional diagram and charge-density of the $\mathrm{NO}_{2}$ MO are shown in Figures 14.3 and 14.4, respectively.

Figure 14.3. The cross section of the $\mathrm{NO}_{2} \mathrm{MO}$ showing the axes, $\sigma$ MOs (two $H_{2}$-type ellipsoidal MOs) with six paired electrons, with the $N 1 s, 2 s$, and $2 p$ AOs and the $O 1 s, 2 s$, and $2 p$ AOs. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $r_{5}$ : radius of the $N 2 p$ shell having one unpaired electron, $r_{6}$ : radius of each $O 2 p$ shell having two paired electrons.

Figure 14.4. $\mathrm{NO}_{2} \mathrm{MO}$ comprising two $\sigma$ MOs ( $\mathrm{H}_{2}$-type MOs) with $N$ and $O$ atoms at the foci that have each donated two electrons to the $\sigma$ MOs and have smaller radii and higher binding energies as a consequence. (A)-(B) Top and side color scale, translucent views of the charge-density of the $\mathrm{NO}_{2} \mathrm{MO}$. (C) Off-center cut-away view showing the complete inner most $\mathrm{N} 1 s$ shell, and moving radially, the $N 2 s$ shell, the $N 2 p$ shell, and the $\sigma$ prolate spheroidal MOs that each have the $N$ atom as a focus. Moving radially from each oxygen-atom focus, the complete innermost $O 1 s$ shell, the $O 2 s$ shell, the $O 2 p$ shell, and the $\sigma$ prolate spheroidal MOs are shown.

## SUM OF THE ENERGIES OF THE $\sigma$ MOS AND THE AOS OF NITROGEN DIOXIDE

The energies of each $\mathrm{NO}_{2} \sigma$ MO are the same as those of $N O$ (Eqs. (13.954-13.958)). They are given by the substitution of the semiprincipal axes (Eqs. (14.102-14.103) and (14.106)) into the energy equations (Eqs. (11.207-11.212)) of $\mathrm{H}_{2}$ except that the terms based on charge are multiplied by four and the kinetic energy term is multiplied by two due to the $\sigma$-MO double bond with two pairs of paired electrons:

$$
\begin{align*}
& V_{e}=2^{2} \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-93.03032 \mathrm{eV}  \tag{14.108}\\
& V_{p}=2^{2} \frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=48.51704 \mathrm{eV}  \tag{14.109}\\
& T=2 \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=9.24176 \mathrm{eV}  \tag{14.110}\\
& V_{m}=2^{2} \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-9.24176 \mathrm{eV}  \tag{14.111}\\
& E_{T}=V_{e}+T+V_{m}+V_{p} \tag{14.112}
\end{align*}
$$

Substitution of Eqs. (11.79) and (14.108-14.111) into Eq. (14.112) gives:

$$
\begin{equation*}
E_{T}(N=O, \sigma)=\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(8 \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-4\right)=-44.51329 \mathrm{eV} \tag{14.113}
\end{equation*}
$$

where $E_{T}(N=O, \sigma)$ is the total energy of each $\sigma \mathrm{MO}$ of $N O_{2}$. The total energy of $N O_{2}, E_{T}\left(N O_{2}\right)$, is given by the sum of $E\left(\right.$ ionization $; N$ ) and E(ionization; $N^{+}$), the sum of the energies of the first and second electrons of nitrogen (Eqs. (14.8814.89)) donated to each double bond, the sum of $E$ (ionization; $O$ ) and two times $E$ (ionization; $O^{+}$), the energies of the first and second electrons of oxygen (Eqs. (14.90-14.91)) donated to the double bonds, $E_{T}(N, 2 p)$, the $N 2 p$ AO contribution due to the decrease in radius with the formation of each bond (Eq. (14.93)), two times $E_{T}(O, 2 p)$, the $O 2 p$ AO contribution due to the decrease in radius with the formation of each bond (Eq. (14.95)), and two times $E_{T}(N=O, \sigma)$, the $\sigma$ MO contribution given by Eq. (14.113):

$$
\begin{align*}
E_{T}\left(N O_{2}\right) & =\left(\begin{array}{l}
\text { E(ionization; } N)+E\left(\text { ionization; } N^{+}\right) \\
+E(\text { ionization; } O)+2 E\left(\text { ionization; } O^{+}\right)+E_{T}(N, 2 p) \\
+2 E_{T}(O, 2 p)+2 E_{T}(N=O, \sigma)
\end{array}\right) \\
& =\left(\begin{array}{l}
14.53414 \mathrm{eV}+29.6013 \mathrm{eV}+13.61806 \mathrm{eV} \\
+2(35.11730 \mathrm{eV})+(-10.68853 \mathrm{eV})+2(-39.92918 \mathrm{eV}) \\
+2\left(\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\binom{a+\sqrt{\frac{a a_{0}}{2}}}{\hline \ln \frac{a-\sqrt{\frac{a a_{0}}{2}}}{}}\right.
\end{array}\right) \\
& =\left(\begin{array}{l}
14.53414 \mathrm{eV}+29.6013 \mathrm{eV}+13.61806 \mathrm{eV} \\
+2(35.11730 \mathrm{eV})+(-10.68853 \mathrm{eV}) \\
+2(-39.92918 \mathrm{eV})+2(-44.51329 \mathrm{eV})
\end{array}\right)=-51.58536 \mathrm{eV} \tag{14.114}
\end{align*}
$$

## VIBRATION OF $\mathrm{NO}_{2}$

The vibrational energy levels of $\mathrm{NO}_{2}$ may be solved by determining the Morse potential curve from the energy relationships for the transition from a $N$ atom and two $O$ atoms whose parameters are given by Eqs. (10.134-10.143) and (10.154-10.163), respectively, to a $N$ atom whose parameter $r_{5}$ is given by Eq. (14.77), two $O$ atoms whose parameter $r_{6}$ is given by Eq. (14.87), and the $\sigma$ MOs whose parameters are given by Eqs. (14.102-14.104) and (14.106-14.107). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K\&P) [4] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

## THE DOPPLER ENERGY TERMS OF NITROGEN DIOXIDE

The equations of the radiation reaction force of nitrogen dioxide are the same as those of NO with the substitution of the $\mathrm{NO}_{2}$ parameters. Using Eq. (13.961), the angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{4 e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}=2.07110 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{14.115}
\end{equation*}
$$

where $a$ is given by Eq. (14.102). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 2.07110 \times 10^{16} \mathrm{rad} / \mathrm{s}=13.63231 \mathrm{eV} \tag{14.116}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(N O_{2}\right) / 2$ for $E_{h \nu}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.116) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-25.79268 \mathrm{eV} \sqrt{\frac{2 e(13.63231 \mathrm{eV})}{m_{e} c^{2}}}=-0.18840 \mathrm{eV} \tag{14.117}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The transition state comprises $\mathrm{O}--\mathrm{NO}$, oxygen binding to NO . As in the case of $\mathrm{CO}_{2}$ bond formation, vibration in the transition state corresponds to $v_{3}$ [5] with the maximum kinetic energy localized to the nascent $N-O$ bond. In this case, the kinetic energy of the nuclei is the maximum for this bond. Thus, $\bar{E}_{\text {Kvib }}$ is the vibrational energy. The decrease in the energy of the $\mathrm{NO}_{2} \mathrm{MO}$ due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.117) and $\bar{E}_{\text {Kvib }}$, the vibrational energy. Using the experimental $\mathrm{NO}_{2} E_{\text {vib }}\left(v_{3}\right)$ of $1618 \mathrm{~cm}^{-1}(0.20061 \mathrm{eV})$ [6] for $\bar{E}_{K v i b}$ of the transition state, $\bar{E}_{\text {osc }}\left(N O_{2}\right)$ is:

$$
\begin{align*}
& \bar{E}_{\text {osc }}\left(N O_{2}\right)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+E_{v i b}  \tag{14.118}\\
& \bar{E}_{\text {osc }}\left(N O_{2}\right)=-0.18840 \mathrm{eV}+0.20061 \mathrm{eV}=0.01221 \mathrm{eV} \tag{14.119}
\end{align*}
$$

## TOTAL AND BOND ENERGIES OF NITROGEN DIOXIDE

$E_{T+o s c}\left(N O_{2}\right)$, the total energy of $N O_{2}$ including the Doppler term, is given by the sum of $E_{T}\left(N O_{2}\right)$ (Eq. (14.114)) and $\bar{E}_{\text {osc }}\left(N O_{2}\right)$ given by Eq. (14.119).

$$
\begin{align*}
& E_{T+o s c}\left(\mathrm{NO}_{2}\right)=\left(\begin{array}{l}
2\left(V_{e}+T+V_{m}+V_{p}\right)+E(\text { ionization } ; N)+E\left(\text { ionization; } N^{+}\right) \\
+E(\text { ionization } ; O)+2 E\left(\text { ionization } ; O^{+}\right) \\
+E_{T}(N, 2 p)+2 E_{T}(O, 2 p)+\bar{E}_{o s c}\left(N O_{2}\right)
\end{array}\right) \\
& =\left(\begin{array}{l}
2 E_{T}(N=O, \sigma)+E(\text { ionization } ; N)+E\left(\text { ionization } ; N^{+}\right) \\
+E(\text { ionization } ; O)+2 E\left(\text { ionization } ; O^{+}\right) \\
+E_{T}(N, 2 p)+2 E_{T}(O, 2 p)+\bar{E}_{\text {osc }}\left(N O_{2}\right)
\end{array}\right)  \tag{14.120}\\
& =E_{T}\left(N O_{2}\right)+\bar{E}_{\text {osc }}\left(N O_{2}\right) \\
& \left(\left(2\left(\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(8 \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-4\right)\right)\right.\right.
\end{align*}
$$

$$
\begin{aligned}
& =-51.58536 \mathrm{eV}-0.18840 \mathrm{eV}+E_{\text {vib }}
\end{aligned}
$$

From Eqs. (14.119-14.121), the total energy of the $\mathrm{NO}_{2} \mathrm{MO}$ is:

$$
\begin{align*}
E_{T+o s c}\left(N O_{2}\right) & =-51.58536 \mathrm{eV}+\bar{E}_{\text {osc }}\left(N O_{2}\right) \\
& =-51.58536 \mathrm{eV}+0.01221 \mathrm{eV}  \tag{14.122}\\
& =-51.57315 \mathrm{eV}
\end{align*}
$$

where the experimental $E_{v i b}$ was used.
As in the case of the dissociation of the bond of the hydroxyl radical, an oxygen atom is formed with dissociation of $\mathrm{NO}_{2} . \quad \mathrm{O}$ has two unpaired electrons as shown in Eq. (13.55) which interact to stabilize the atom as shown by Eq. (10.16110.162). The lowering of the energy of the reactants decreases the bond energy. Thus, the total energy of oxygen is reduced by the energy in the field of the two magnetic dipoles given by Eq. (7.46) and Eq. (13.101).

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} a_{0}^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{a_{0}^{3}}=0.11441 \mathrm{eV} \tag{14.123}
\end{equation*}
$$

The $\mathrm{NO}_{2}$ bond dissociation energy, $E_{D}\left(\mathrm{NO}_{2}\right)$, is given by the sum of the energies of the $N O$ and the $O$ atom minus the sum of $E_{T+o s c}\left(\mathrm{NO}_{2}\right)$ and $E$ (magnetic) :

$$
\begin{equation*}
E_{D}\left(N O_{2}\right)=E(N O)+E(O)-\left(E(\text { magnetic })+E_{T+o s c}\left(N O_{2}\right)\right) \tag{14.124}
\end{equation*}
$$

The energy of an oxygen atom is given by the negative of Eq. (14.90), and $E_{T}(N O)$ is given by the sum of the experimental energies of $N$ (negative of Eq. (14.88)), $O$, and the negative of the bond energy of $N O$ (Eq. (13.974)).

$$
\begin{equation*}
E(N O)=-14.53414 \mathrm{eV}-13.618060 \mathrm{eV}-6.53529 \mathrm{eV}=-34.68749 \mathrm{eV} \tag{14.125}
\end{equation*}
$$

Thus, the $\mathrm{NO}_{2}$ bond dissociation energy, $E_{D}\left(\mathrm{NO}_{2}\right)$, given by Eqs. (4.90) and (14.112-14.125) is:

$$
\begin{align*}
E_{D}\left(N O_{2}\right) & =-(34.68749 \mathrm{eV}+13.618060 \mathrm{eV})-\left(E(\text { magnetic })+E_{T+o s c}\left(N O_{2}\right)\right)  \tag{14.126}\\
& =-48.30555 \mathrm{eV}-(0.11441 \mathrm{eV}-51.57315 \mathrm{eV})=3.15319 \mathrm{eV}
\end{align*}
$$

The experimental $\mathrm{NO}_{2}$ bond dissociation energy is [7]:

$$
\begin{equation*}
E_{D 298}\left(N O_{2}\right)=3.161 \mathrm{eV} \tag{14.127}
\end{equation*}
$$

## BOND ANGLE OF $\mathrm{NO}_{2}$

The $\mathrm{NO}_{2} \mathrm{MO}$ comprises a linear combination of two $\mathrm{N}=O$-bond MOs. A bond is also possible between the two $O$ atoms of the $N=O$ bonds. Such $O=O$ bonding would decrease the $N=O$ bond strength since electron density would be shifted from the $N=O$ bonds to the $O=O$ bond. Thus, the bond angle between the two $N=O$ bonds is determined by the condition that the total energy of the $\mathrm{H}_{2}$-type ellipsoidal MO between the terminal $O$ atoms of the $N=O$ bonds is zero. From Eqs. (11.79) and (13.228), the distance from the origin to each focus of the $O=O$ ellipsoidal MO is:

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 2 a}}=\sqrt{\frac{a a_{0}}{2}} \tag{14.128}
\end{equation*}
$$

The internuclear distance from Eq. (13.229) is:

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{\frac{a a_{0}}{2}} \tag{14.129}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal $O=O$ MO $b=c$ is given by Eq. (13.167).
The component energies and the total energy $E_{T}$ of the $O=O$ bond are given by the energy equations (Eqs. (11.20711.212), (11.213-11.217), and (11.239)) of $H_{2}$ except that the terms based on charge are multiplied by four and the kinetic energy term is multiplied by two due to the $O=O$ double bond with two pairs of paired electrons. Substitution of Eq. (14.128) into Eqs. (11.207-11.212) gives:

$$
0=\left[\begin{array}{l}
\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left(\frac{a+\sqrt{\frac{a a_{0}}{2}}}{8 \ln \frac{a-\sqrt{\frac{a a_{0}}{2}}}{2}}\right) 4 \tag{14.130}
\end{array}\right)\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{\frac{4 \pi \varepsilon_{0} a^{3}}{m_{e}}}{m_{e} c^{2}}}}{}}\right][
$$

From the energy relationship given by Eq. (14.130) and the relationship between the axes given by Eqs. (14.128-14.129) and (13.167-14.168), the dimensions of the $O=O \mathrm{MO}$ can be solved.

The most convenient way to solve Eq. (14.130) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a=8.3360 a_{0}=4.4112 \times 10^{-10} \mathrm{~m} \tag{14.131}
\end{equation*}
$$

Substitution of Eq. (14.131) into Eq. (14.128) gives:

$$
\begin{equation*}
c^{\prime}=2.0416 a_{0}=1.0804 \times 10^{-10} \mathrm{~m} \tag{14.132}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.132) by two is:

$$
\begin{equation*}
2 c^{\prime}=4.0831 a_{0}=2.1607 \times 10^{-10} \mathrm{~m} \tag{14.133}
\end{equation*}
$$

Substitution of Eqs. (14.131-14.132) into Eq. (14.167) gives:

$$
\begin{equation*}
b=c=8.0821 a_{0}=4.2769 \times 10^{-10} \mathrm{~m} \tag{14.134}
\end{equation*}
$$

Substitution of Eqs. (14.131-14.132) into Eq. (14.168) gives:

$$
\begin{equation*}
e=0.2449 \tag{14.135}
\end{equation*}
$$

From, $2 c^{\prime}{ }_{C=C}$ (Eq. (14.133)), the distance between the two $O$ atoms when the total energy of the corresponding MO is zero (Eq. (14.130)), and $2{c^{\prime}}_{N=O}$ (Eq. (14.104)), the internuclear distance of each $N=O$ bond, the corresponding bond angle can be determined from the law of cosines. Using, Eqs. (13.240-13.242), the bond angle $\theta$ between the $N=O$ bonds is:

$$
\begin{equation*}
\theta=\cos ^{-1}\left(\frac{2(2.24347)^{2}-(4.0831)^{2}}{2(2.24347)^{2}}\right)=\cos ^{-1}(-0.6562)=131.012^{\circ} \tag{14.136}
\end{equation*}
$$

The experimental angle between the $N=O$ bonds is [3]:

$$
\begin{equation*}
\theta=134.1^{\circ} \tag{14.137}
\end{equation*}
$$

The results of the determination of bond parameters of $\mathrm{NO}_{2}$ are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## ETHANE MOLECULE ( $\mathrm{CH}_{3} \mathrm{CH}_{3}$ )

The ethane molecule $\mathrm{CH}_{3} \mathrm{CH}_{3}$ is formed by the reaction of two methyl radicals:

$$
\begin{equation*}
\mathrm{CH}_{3}+\mathrm{CH}_{3} \rightarrow \mathrm{CH}_{3} \mathrm{CH}_{3} \tag{14.138}
\end{equation*}
$$

$\mathrm{CH}_{3} \mathrm{CH}_{3}$ can be solved using the same principles as those used to solve $\mathrm{CH}_{3}$, wherein the $2 s$ and $2 p$ shells of each C hybridize to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. First, two sets of three $H$ atomic orbitals (AOs) combine with two sets of three carbon $2 s p^{3}$ HOs to form two methyl groups comprising a linear combination of six diatomic $\mathrm{H}_{2}$-type MOs developed in the Nature of the Chemical Bond of HydrogenType Molecules and Molecular Ions section. Then, the two $\mathrm{CH}_{3}$ groups bond by forming a $\mathrm{H}_{2}$-type MO between the remaining $C 2 s p^{3} \mathrm{HO}$ on each carbon.

## FORCE BALANCE OF THE $C-C$-BOND MO OF ETHANE

$\mathrm{CH}_{3} \mathrm{CH}_{3}$ comprises a chemical bond between two $\mathrm{CH}_{3}$ radicals wherein each methyl radical comprises three chemical bonds between carbon and hydrogen atoms. The solution of the parameters of $\mathrm{CH}_{3}$ is given in the Methyl Radical $\left(\mathrm{CH}_{3}\right)$ section. Each $\mathrm{C}-\mathrm{H}$ bond of $\mathrm{CH}_{3}$ having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of $75 \% \mathrm{H}_{2}$-type ellipsoidal MO and $25 \% \mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO}$. The proton of the $H$ atom and the nucleus of the $C$ atom are along each internuclear axis and serve as the foci. As in the case of $H_{2}$, each of the three $\mathrm{C}-\mathrm{H}$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $C 2 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C 2 s p^{3}$ shell since it is energetically unfavorable. Thus, each MO surface comprises a prolate spheroid at the $H$ proton that is continuous with the $C 2 s p^{3}$ shell at the $C$ atom whose nucleus serves as the other focus. The electron configuration and the energy, $E\left(C, 2 s p^{3}\right)$, of the $C 2 s p^{3}$ shell is given by Eqs. (13.422) and (13.428), respectively. The central paramagnetic force due to spin of each $C-H$ bond is provided by the spin-pairing force of the $\mathrm{CH}_{3} \mathrm{MO}$ that has the symmetry of an $s$ orbital that superimposes with the $C 2 s p^{3}$ orbitals such that the corresponding angular momenta are unchanged.

Two $\mathrm{CH}_{3}$ radicals bond to form $\mathrm{CH}_{3} \mathrm{CH}_{3}$ by forming a MO between the two remaining $\mathrm{C} 2 s p^{3}$ - HO electrons of the two carbon atoms. However, in this case, the sharing of electrons between two $C 2 s p^{3} \mathrm{HOs}$ to form a molecular orbital (MO) comprising two spin-paired electrons permits each $C 2 s p^{3} \mathrm{HO}$ to decrease in radius and energy.

As in the case of the $C-H$ bonds, the $C-C$-bond MO is a prolate-spheroidal-MO surface that cannot extend into $C 2 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C 2 s p^{3}$ shell of each atom. Thus, the MO surface comprises a partial prolate spheroid in between the carbon nuclei and is continuous with the $C 2 s p^{3}$ shell at each $C$ atom. The energy of the $H_{2}$ type ellipsoidal MO is matched to that of the $C 2 s p^{3}$ shell. As in the case of previous examples of energy-matched MOs such as those of $\mathrm{OH}, \mathrm{NH}, \mathrm{CH}$, and the $\mathrm{C}=\mathrm{O}$-bond MO of $\mathrm{CO}_{2}$, the $\mathrm{C}-\mathrm{C}$-bond MO of ethane must comprise $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO in order to match potential, kinetic, and orbital energy relationships. Thus, the $C-C$-bond MO must comprise two $\mathrm{C} 2 s p^{3} \mathrm{HOs}$ and $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO divided between the two $C 2 s p^{3} \mathrm{HOs}$ :

$$
\begin{equation*}
2 \mathrm{C} 2 s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO} \rightarrow \mathrm{C}-\mathrm{C} \text { - bond } \mathrm{MO} \tag{14.139}
\end{equation*}
$$

The linear combination of the $H_{2}$-type ellipsoidal MO with each $C 2 s p^{3} \mathrm{HO}$ further comprises an excess $25 \%$ charge-density contribution from each $C 2 s p^{3} \mathrm{HO}$ to the $C-C$-bond MO to achieve an energy minimum. The force balance of the $C-C$-bond

MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.139) and the energy matching condition between the $\mathrm{C} 2 s p^{3}-\mathrm{HO}$ components of the MO.

Similarly, the energies of each $\mathrm{CH}_{3}$ MO involve each $C 2 s p^{3}$ and each $H 1 s$ electron with the formation of each $C-H$ bond. The sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $C 2 s p^{3}$ shell. This energy is determined by the considering the effect of the donation of $25 \%$ electron density from the two $C 2 s p^{3}$ HOs to the $C-C$-bond MO. The $2 s p^{3}$ hybridized orbital arrangement given by Eq. (13.422) is:

\[

\]

where the quantum numbers $\left(\ell, m_{\ell}\right)$ are below each electron. The total energy of the state is given by the sum over the four electrons. The sum $E_{T}\left(C, 2 s p^{3}\right)$ of calculated energies of $C, C^{+}, C^{2+}$, and $C^{3+}$ from Eqs. (10.123), (10.113-10.114), (10.68), and (10.48), respectively, is:

$$
\begin{equation*}
E_{T}\left(C, 2 s p^{3}\right)=64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+11.27671 \mathrm{eV}=148.25751 \mathrm{eV} \tag{14.141}
\end{equation*}
$$

which agrees well with the sum of 148.02532 eV from the experimental [2] values. Consider the case of the $C 2 s p^{3} \mathrm{HO}$ of each methyl radical. The orbital-angular-momentum interactions cancel such that the energy of the $E_{T}\left(C, 2 s p^{3}\right)$ is purely Coulombic. By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{2 s p^{3}}$ of the $C 2 s p^{3}$ shell may be calculated from the Coulombic energy using Eq. (10.102):

$$
\begin{equation*}
r_{2 s p^{3}}=\sum_{n=2}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 148.25751 \mathrm{eV})}=\frac{10 e^{2}}{8 \pi \varepsilon_{0}(e 148.25751 \mathrm{eV})}=0.91771 a_{0} \tag{14.142}
\end{equation*}
$$

where $Z=6$ for carbon. Using Eqs. (10.102) and (14.142), the Coulombic energy $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{2 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.91771 a_{0}}=-14.82575 \mathrm{eV} \tag{14.143}
\end{equation*}
$$

During hybridization, the spin-paired $2 s$ electrons are promoted to the $C 2 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (13.152) at the initial radius of the $2 s$ electrons. From Eq. (10.62) with $Z=6$, the radius $r_{3}$ of the $C 2 s$ shell is:

$$
\begin{equation*}
r_{3}=0.84317 a_{0} \tag{14.144}
\end{equation*}
$$

Using Eqs. (13.152) and (14.144), the unpairing energy is:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.84317 a_{0}\right)^{3}}=0.19086 \mathrm{eV} \tag{14.145}
\end{equation*}
$$

Using Eqs. (14.143) and (14.145), the energy $E\left(C, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(C, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-14.82575 \mathrm{eV}+0.19086 \mathrm{eV}=-14.63489 \mathrm{eV} \tag{14.146}
\end{equation*}
$$

Next, consider the formation of the $C-C$-bond MO of ethane from two methyl radicals, each having a $C 2 s p^{3}$ electron with an energy given by Eq. (14.146). The total energy of the state is given by the sum over the four electrons. The sum $E_{T}\left(C_{\text {ethane }}, 2 s p^{3}\right)$ of calculated energies of $C 2 s p^{3}, C^{+}, C^{2+}$, and $C^{3+}$ from Eqs. (10.123), (10.113-10.114), (10.68), and (10.48), respectively, is:

$$
\begin{align*}
E_{T}\left(C_{\text {ethane }}, 2 s p^{3}\right) & =-\left(64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+E\left(C, 2 s p^{3}\right)\right) \\
& =-(64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+14.63489 \mathrm{eV})  \tag{14.147}\\
& =-151.61569 \mathrm{eV}
\end{align*}
$$

where $E\left(C, 2 s p^{3}\right)$ is the sum of the energy of $C,-11.27671 \mathrm{eV}$, and the hybridization energy. The orbital-angular-momentum
interactions also cancel such that the energy of the $E_{T}\left(C_{\text {ethane }}, 2 s p^{3}\right)$ is purely Coulombic.
The sharing of electrons between two $C 2 s p^{3}$ HOs to form a $C-C$-bond MO permits each participating hybridized orbital to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each $C 2 s p^{3}$ HO donates an excess of $25 \%$ of its electron density to the $C-C$-bond MO to form an energy minimum. By considering this electron redistribution in the ethane molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{\text {ethane2sp }}$ of the $C 2 s p^{3}$ shell of ethane may be calculated from the Coulombic energy using Eq. (10.102).

$$
\begin{equation*}
r_{\text {ethane } 2 s p^{3}}=\left(\sum_{n=2}^{5}(Z-n)-0.25\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 151.61569 \mathrm{eV})}=\frac{9.75 e^{2}}{8 \pi \varepsilon_{0}(\mathrm{e} 151.61569 \mathrm{eV})}=0.87495 a_{0} \tag{14.148}
\end{equation*}
$$

Using Eqs. (10.102) and (14.148), the Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {ethane }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(C_{\text {ethane }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {ethane2 } 2 p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.87495 a_{0}}=-15.55033 \mathrm{eV} \tag{14.149}
\end{equation*}
$$

During hybridization, the spin-paired $2 s$ electrons are promoted to the $C 2 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (13.152). Using Eqs. (14.145) and (14.149), the energy $E\left(C_{\text {ethane }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(C_{\text {ethane }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {ethane } 2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-15.55033 \mathrm{eV}+0.19086 \mathrm{eV}=-15.35946 \mathrm{eV} \tag{14.150}
\end{equation*}
$$

Thus, $E_{T}\left(C-C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell with the formation of the $C-C$-bond MO is given by the difference between Eq. (14.146) and Eq. (14.150).

$$
\begin{equation*}
E_{T}\left(C-C, 2 s p^{3}\right)=E\left(C_{\text {ethane }}, 2 s p^{3}\right)-E\left(C, 2 s p^{3}\right)=-15.35946 \mathrm{eV}-(-14.63489 \mathrm{eV})=-0.72457 \mathrm{eV} \tag{14.151}
\end{equation*}
$$

The $H_{2}$-type ellipsoidal MO comprises $75 \%$ of the $C-C$-bond MO shared between two $C 2 s p^{3}$ HOs corresponding to the electron charge density in Eq. (11.65) of $\frac{-0.75 e}{2}$. But, the additional $25 \%$ charge-density contribution to the $C-C$-bond MO causes the electron charge density in Eq. (11.65) to be $\frac{-e}{2}=-0.5 e$. Thus, the force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ in terms of the central force of the foci given by Eq. (11.65) is:

$$
\begin{equation*}
k^{\prime}=\frac{(0.5) 2 e^{2}}{4 \pi \varepsilon_{0}} \tag{14.152}
\end{equation*}
$$

The distance from the origin to each focus $c^{\prime}$ is given by substitution of Eq. (14.152) into Eq. (13.60). Thus, the distance from the origin of the $C-C$-bond MO to each focus $c^{\prime}$ is given by:

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} a}}=\sqrt{a a_{0}} \tag{14.153}
\end{equation*}
$$

The internuclear distance from Eq. (14.153) is:

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{a a_{0}} \tag{14.154}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal $C-C$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of the $C-C$-bond MO. Since the $C-C$-bond MO comprises a $H_{2}$-type-ellipsoidal MO that transitions to the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$ of each carbon, the energy $E\left(C_{\text {ethane }}, 2 s p^{3}\right)$ in Eq. (14.150) adds to that of the $H_{2}$-type ellipsoidal MO to give the total energy of the $C-C$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the $C-C$-bond MO are solved. Similarly, $E\left(C_{\text {ethane }}, 2 s p^{3}\right)$ is added to the energy of the $H_{2}$-type ellipsoidal MO of each $C-H$ bond of the methyl groups to give its total energy. From the energy equation and the relationship between the axes, the dimensions of the equivalent $C-H$-bond MOs of the methyl groups in ethane are solved.

The general equations for the energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ of the $C-C$-bond MO are the same as those of the CH MO as well as each $C-H$-bond MO of the methyl groups except that energy of the $C_{\text {ethane }} 2 s p^{3}$ HO is used. Since the prolate spheroidal $H_{2}$-type MO transitions to the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$ of each carbon and the energy of the $C_{\text {ethane }} 2 s p^{3}$ shell must remain constant and equal to the $E\left(C_{\text {ethane }}, 2 s p^{3}\right)$ given by Eq. (14.150), the total energy $E_{T}(C-C, \sigma)$ of the $\sigma$ component of the $C-C$-bond MO is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$ and the $\mathrm{H}_{2}$-type ellipsoidal MO that forms the $\sigma$ component of the $C-C$-bond MO as given by Eq. (14.139) with the electron charge redistribution. Using Eqs. (13.431) and (14.150), $E_{T}(C-C, \sigma)$ is given by:

$$
\begin{equation*}
E_{T}(C-C, \sigma)=E_{T}+E\left(C_{\text {ethane }}, 2 s p^{3}\right)=-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.35946 \mathrm{eV} \tag{14.155}
\end{equation*}
$$

To match the boundary condition that the total energy of the entire the $H_{2}$-type ellipsoidal MO is given by Eqs. (11.212) and (13.75), $E_{T}(C-C, \sigma)$ given by Eq. (14.155) is set equal to Eq. (13.75):

$$
\begin{equation*}
E_{T}(C-C, \sigma)=-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.35946 \mathrm{eV}=-31.63536831 \mathrm{eV} \tag{14.156}
\end{equation*}
$$

From the energy relationship given by Eq. (14.156) and the relationship between the axes given by Eqs. (14.153-14.154) and (13.62-13.63), the dimensions of the $C-C$-bond MO can be solved.

Substitution of Eq. (14.153) into Eq. (14.156) gives:

$$
\begin{equation*}
\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a a_{0}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{a a_{0}}}{a-\sqrt{a a_{0}}}-1\right]=e 16.27589 \tag{14.157}
\end{equation*}
$$

The most convenient way to solve Eq. (14.157) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is

$$
\begin{equation*}
a=2.10725 a_{0}=1.11511 \times 10^{-10} \mathrm{~m} \tag{14.158}
\end{equation*}
$$

Substitution of Eq. (14.158) into Eq. (14.153) gives:

$$
\begin{equation*}
c^{\prime}=1.45164 a_{0}=7.68173 \times 10^{-11} \mathrm{~m} \tag{14.159}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.159) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.90327 a_{0}=1.53635 \times 10^{-10} \mathrm{~m} \tag{14.160}
\end{equation*}
$$

The experimental bond distance is [3]:

$$
\begin{equation*}
2 c^{\prime}=1.5351 \times 10^{-10} \mathrm{~m} \tag{14.161}
\end{equation*}
$$

Substitution of Eqs. (14.158-14.159) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=1.52750 a_{0}=8.08317 \times 10^{-11} \mathrm{~m} \tag{14.162}
\end{equation*}
$$

Substitution of Eqs. (14.158-14.159) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.68888 \tag{14.163}
\end{equation*}
$$

The nucleus of the $C$ atoms comprise the foci of the $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{\text {ethane } 2 s p^{3}}=0.87495 a_{0}$ is the radius of the $C_{\text {ethane }} 2 s p^{3}$ shell. Substitution of Eqs. (14.158-14.159) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=67.33^{\circ} \tag{14.164}
\end{equation*}
$$

Then, the angle $\theta_{C-C_{e t h a n e} 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C-C_{\text {ehane }} 2 s p^{3} H O}=180^{\circ}-67.33^{\circ}=112.67^{\circ} \tag{14.165}
\end{equation*}
$$

as shown in Figure 14.5.

Figure 14.5. The cross section of the $C-C$-bond $\mathrm{MO}(\sigma \mathrm{MO})$ and one $C-H$-bond MO of ethane showing the axes, angles, and point of intersection of each $H_{2}$-type ellipsoidal MO with the corresponding $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$. The continuation of each $H_{2}$-type-ellipsoidal-MO basis element of the $C-C$ bond and the $C-H$-bond beyond the intersection point with each $C_{\text {ethane }} 2 s p^{3}$ shell and $\sigma \mathrm{MO}$ is shown as dashed since each only serves to solve the energy match with the $C_{\text {ethane }} 2 s p^{3}$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of each intersection point. The actual charge density is shown by the solid lines. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $d_{1}: d_{C-C_{\text {ethane }}, H_{2} M O}, \quad \theta_{1}: \theta_{C-C_{\text {ethane }} 2 s p^{3} H O}, \quad d_{2}: d_{C-C_{\text {ethane }} 2 s p^{3} H O}, \quad R: r_{\text {ethane } 22 s p^{3}}, \quad d_{3}: d_{C-H_{\text {ethane }}, H_{2} M O}, \quad \theta_{2}: \theta_{C-H_{\text {ethane }} 2 s p^{3} H O}, \quad$ and $d_{4}: d_{C-H_{\text {ethane }} 2 s p^{3} H O}$.

Consider the right-hand intersection point. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$ coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{C-C_{e l h a n e}, H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{\text {ethane } 2 s p^{3}} \sin \theta_{C-C_{\text {ethane }} 2 s p^{3} H O}=0.87495 a_{0} \sin \theta_{C-C_{\text {ethane }} 2 s p^{3} H O}=b \sin \theta_{C-C_{\text {ethane }}, H_{2} M O} \tag{14.166}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{C-C_{\text {ethane }}, H_{2} M O}=\sin ^{-1} \frac{0.87495 a_{0} \sin \theta_{C-C_{\text {ethane }} 2 s p^{3} H O}}{b}=\sin ^{-1} \frac{0.87495 a_{0} \sin 112.67^{\circ}}{b} \tag{14.167}
\end{equation*}
$$

with the use of Eq. (14.166). Substitution of Eq. (14.162) into Eq. (14.167) gives:

$$
\begin{equation*}
\theta_{C-C_{\text {ethane }}, H_{2} M O}=31.91^{\circ} \tag{14.168}
\end{equation*}
$$

Then, the distance $d_{C-C_{\text {ethane }}, H_{2} M O}$ along the internuclear axis from the origin of $H_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C-C_{\text {ethane }}, \mathrm{H}_{2} \mathrm{MO}}=a \cos \theta_{C-C_{\text {ethane }}, \mathrm{H}_{2} \mathrm{MO}} \tag{14.169}
\end{equation*}
$$

Substitution of Eqs. (14.158) and (14.168) into Eq. (14.169) gives:

$$
\begin{equation*}
d_{C-C_{\text {ethane },} H_{2} M O}=1.78885 a_{0}=9.46617 \times 10^{-11} \mathrm{~m} \tag{14.170}
\end{equation*}
$$

The distance $d_{C-C_{\text {elhane }} 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C-C_{\text {elhane }} 2 s p^{3} \mathrm{HO}}=d_{C-C_{\text {ethane },} \mathrm{H}_{2} \mathrm{MO}}-c^{\prime} \tag{14.171}
\end{equation*}
$$

Substitution of Eqs. (14.159) and (14.170) into Eq. (14.171) gives:

$$
\begin{equation*}
d_{C-C_{\text {ethane }} 2 s p^{3} H O}=0.33721 a_{0}=1.78444 \times 10^{-11} \mathrm{~m} \tag{14.172}
\end{equation*}
$$

## FORCE BALANCE OF THE $\mathrm{CH}_{3}$ MOS OF ETHANE

Each of the two equivalent $\mathrm{CH}_{3}$ MOs must comprise three $\mathrm{C}-\mathrm{H}$ bonds with each comprising $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO and a $C 2 s p^{3} \mathrm{HO}$ as given by Eq. (13.540):

$$
\begin{equation*}
3\left[1{\mathrm{C} 2 s p^{3}}^{+} 0.75 \mathrm{H}_{2} \mathrm{MO}\right] \rightarrow \mathrm{CH}_{3} \mathrm{MO} \tag{14.173}
\end{equation*}
$$

The force balance of the $\mathrm{CH}_{3} \mathrm{MO}$ is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.540) and the energy matching condition between the hydrogen and $C 2 s p^{3} \mathrm{HO}$ components of the MO.

The force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ of the each $H_{2}$-type-ellipsoidal-MO component of the $\mathrm{CH}_{3} \mathrm{MO}$ in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $\mathrm{C}-\mathrm{H}$-bond MO to each focus $c^{\prime}$ is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $\mathrm{C}-\mathrm{H}-$ bond MO. Since each of the three prolate spheroidal $\mathrm{C}-\mathrm{H}$-bond MOs comprises an $H_{2}$-type-ellipsoidal MO that transitions to the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$ of ethane, the energy $E\left(C_{\text {ethane }}, 2 s p^{3}\right)$ of Eq. (14.150) adds to that of the three corresponding $H_{2}$-type ellipsoidal MOs to give the total energy of the $\mathrm{CH}_{3} \mathrm{MO}$. From the energy equation and the relationship between the axes, the dimensions of the $\mathrm{CH}_{3} \mathrm{MO}$ are solved.

The energy components of $V_{e}, V_{p}, T$, and $V_{m}$ are the same as those of methyl radical, three times those of CH corresponding to the three $C-H$ bonds except that energy of the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$ is used. Since each prolate spheroidal $H_{2}$-type MO transitions to the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$ and the energy of the $C_{\text {ethane }} 2 s p^{3}$ shell must remain constant and equal to the $E\left(C_{\text {ethane }}, 2 s p^{3}\right)$ given by Eq. (14.150), the total energy $E_{T_{\text {chanee }}}\left(\mathrm{CH}_{3}\right)$ of the $\mathrm{CH}_{3} \mathrm{MO}$ is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $C_{\text {ehane }} 2 s p^{3} \mathrm{HO}$ and the three $H_{2}$-type ellipsoidal MOs that forms the $\mathrm{CH}_{3} \mathrm{MO}$ as given by Eq. (13.540). Using Eq. (13.431), $E_{T_{\text {echemene }}}\left(\mathrm{CH}_{3}\right)$ is given by:

$$
\begin{equation*}
E_{T_{\text {chane }}}\left(\mathrm{CH}_{3}\right)=E_{T}+E\left(C_{\text {ethane }}, 2 s p^{3}\right)=-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.35946 \mathrm{eV} \tag{14.174}
\end{equation*}
$$

$E_{T_{\text {ehane }}}\left(\mathrm{CH}_{3}\right)$ given by Eq. (14.174) is set equal to three times the energy of the $H_{2}$-type ellipsoidal MO minus two times the Coulombic energy of $H$ given by Eq. (13.542):

$$
\begin{equation*}
E_{T}\left(\mathrm{CH}_{3}\right)=-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.35946 \mathrm{eV}=-67.69450 \mathrm{eV} \tag{14.175}
\end{equation*}
$$

From the energy relationship given by Eq. (14.175) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the $\mathrm{CH}_{3}$ MO can be solved.

Substitution of Eq. (13.60) into Eq. (14.175) gives:

$$
\begin{equation*}
\frac{3 e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right]=e 52.33505 \tag{14.176}
\end{equation*}
$$

The most convenient way to solve Eq. (14.176) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is:

$$
\begin{equation*}
a=1.64469 a_{0}=8.70331 \times 10^{-11} \mathrm{~m} \tag{14.177}
\end{equation*}
$$

Substitution of Eq. (14.177) into Eq. (14.60) gives:

$$
\begin{equation*}
c^{\prime}=1.04712 a_{0}=5.54111 \times 10^{-11} \mathrm{~m} \tag{14.178}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.178) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.09424 a_{0}=1.10822 \times 10^{-10} \mathrm{~m} \tag{14.179}
\end{equation*}
$$

The experimental bond distance is [3]:

$$
\begin{equation*}
2 c^{\prime}=1.0940 \times 10^{-10} \mathrm{~m} \tag{14.180}
\end{equation*}
$$

Substitution of Eqs. (14.177-14.178) into Eq. (14.62) gives:

$$
\begin{equation*}
b=c=1.26828 a_{0}=6.71145 \times 10^{-11} \mathrm{~m} \tag{14.181}
\end{equation*}
$$

Substitution of Eqs. (14.177-14.178) into Eq. (14.63) gives:

$$
\begin{equation*}
e=0.63667 \tag{14.182}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $C$ atom comprise the foci of each $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{\text {ehane2sp }}=0.87495 a_{0}$ is the radius of the $C_{\text {ethane }} 2 s p^{3}$ shell. Substitution of Eqs. (14.177-14.178) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=79.34^{\circ} \tag{14.183}
\end{equation*}
$$

Then, the angle $\theta_{C-H_{\text {ethane }} 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C-H_{\text {ethane }} 2 s p^{3} H O}=180^{\circ}-79.34^{\circ}=100.66^{\circ} \tag{14.184}
\end{equation*}
$$

as shown in Figure 14.6.

Figure 14.6. The cross section of one $C-H$-bond MO of ethane showing the axes, angles, and point of intersection of the $H_{2}$-type ellipsoidal MO with the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$. The continuation of the $H_{2}$-type-ellipsoidal-MO basis element beyond the intersection point with the $C_{\text {ethane }} 2 s p^{3}$ shell is shown as dashed since it only serves to solve the energy match with the $C_{\text {ethane }} 2 s p^{3}$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of the intersection point. The actual charge density is shown by the solid lines. Legend: $a$ : semimajor axis, $b:$ semiminor axis, $c^{\prime}$ : internuclear distance, $d_{1}: d_{C-H_{\text {ethane }}, H_{2} M O}, \theta_{1}: \theta_{C-H_{\text {ethane }} 2 s p^{3} H O}, d_{2}: d_{C-H_{\text {ethane }} 2 s p^{3} H O}$, and $R: r_{\text {ethane } 2 s p^{3}}$.

The Cartesian i-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{C-H_{\text {ethane }}, H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{\text {ethane } 2 s p^{3}} \sin \theta_{C-H_{\text {ethane }} 2 s p^{3} H O}=0.87495 a_{0} \sin \theta_{C-H_{\text {ethane }} 2 s p^{3} H O}=b \sin \theta_{C-H_{\text {ethane }}, H_{2} M O} \tag{14.185}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{C-H_{\text {ethane }}, H_{2} M O}=\sin ^{-1} \frac{0.87495 a_{0} \sin \theta_{C-H_{\text {ethane }} 2 s p^{3} H O}}{b}=\sin ^{-1} \frac{0.87495 a_{0} \sin 100.66^{\circ}}{b} \tag{14.186}
\end{equation*}
$$

with the use of Eq. (14.184). Substitution of Eq. (14.181) into Eq. (14.186) gives:

$$
\begin{equation*}
\theta_{C-H_{\text {ethane }}, H_{2} M O}=42.68^{\circ} \tag{14.187}
\end{equation*}
$$

Then, the distance $d_{C-H_{\text {ethane }}, H_{2} M O}$ along the internuclear axis from the origin of $H_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C-H_{\text {ethane }}, H_{2} M O}=a \cos \theta_{C-H_{\text {ethane }}, H_{2} M O} \tag{14.188}
\end{equation*}
$$

Substitution of Eqs. (14.177) and (14.187) into Eq. (14.188) gives:

$$
\begin{equation*}
d_{C-H_{\text {ethane }}, H_{2} M O}=1.20901 a_{0}=6.39780 \times 10^{-11} \mathrm{~m} \tag{14.189}
\end{equation*}
$$

The distance $d_{C-H_{\text {ethane }} 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by

$$
\begin{equation*}
d_{C-\mathrm{H}_{\text {ethane }} 2 s p^{3} \mathrm{HO}}=d_{C-\mathrm{H}_{\text {ethane }}, \mathrm{H}_{2} \mathrm{MO}}-c^{\prime} \tag{14.190}
\end{equation*}
$$

Substitution of Eqs. (14.178) and (14.189) into Eq. (14.190) gives:

$$
\begin{equation*}
d_{C-H_{\text {ethane }} 2 s p^{3} H O}=0.16189 a_{0}=8.56687 \times 10^{-12} \mathrm{~m} \tag{14.191}
\end{equation*}
$$

## BOND ANGLE OF THE $\mathrm{CH}_{3}$ GROUPS

Each $\mathrm{CH}_{3}$ MO comprises a linear combination of three $\mathrm{C}-\mathrm{H}$-bond MOs. Each $\mathrm{C}-H$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$. A bond is also possible between the two H atoms of the $\mathrm{C}-\mathrm{H}$ bonds. Such $H-H$ bonding would decrease the $C-H$ bond strength since electron density would be shifted from the $C-H$ bonds to the $H-H$ bond. Thus, the bond angle between the two $C-H$ bonds is determined by the condition that the total energy of the $H_{2}$-type ellipsoidal MO between the terminal $H$ atoms of the $C-H$ bonds is zero. From Eqs. (11.79) and (13.228), the distance from the origin to each focus of the $H-H$ ellipsoidal MO is:

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 2 a}}=\sqrt{\frac{a a_{0}}{2}} \tag{14.192}
\end{equation*}
$$

The internuclear distance from Eq. (13.229) is:

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{\frac{a a_{0}}{2}} \tag{14.193}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal $H-H$ MO $b=c$ is given by Eq. (14.62).
The bond angle of the $\mathrm{CH}_{3}$ groups of ethane is derived by using the orbital composition and an energy matching factor as in the case with the $\mathrm{CH}_{3}$ radical. Since the two $\mathrm{H}_{2}$-type ellipsoidal MOs initially comprise $75 \%$ of the $H$ electron density of $H_{2}$ and the energy of each $H_{2}$-type ellipsoidal MO is matched to that of the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$, the component energies and the total energy $E_{T}$ of the $H-H$ bond are given by Eqs. (13.67-13.73) except that $V_{e}, T$, and $V_{m}$ are corrected for the hybridization-energy-matching factor of 0.87495 . Hybridization with $25 \%$ electron donation to the $C-C$-bond gives rise to the $C_{\text {ethane }} 2 s p^{3}$ HO-shell Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {ethane }}, 2 s p^{3}\right)$ given by Eq. (14.149). The corresponding normalization factor for determining the zero of the total $H-H$ bond energy is given by the ratio of 15.55033 eV , the magnitude of $E_{\text {Coulomb }}\left(C_{\text {ethane }}, 2 s p^{3}\right)$ given by Eq. (14.149), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). The hybridization energy factor $C_{\text {ethaneC } 2 s p^{3} H O}$ is:

$$
\begin{equation*}
C_{\text {ethaneC } 2 s p^{3} H O}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} r_{\text {ethane } 2 s p^{3}}}}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} 0.87495 a_{0}}}=\frac{13.605804 \mathrm{eV}}{15.55033 \mathrm{eV}}=0.87495 \tag{14.194}
\end{equation*}
$$

Substitution of Eq. (14.152) into Eq. (13.233) with the hybridization factor of 0.87495 gives:

$$
0=\left[\begin{array}{l}
\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left[(0.87495)^{-1}\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right]\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}}{m_{e} c^{2}}}\right]  \tag{14.195}\\
+\hbar \sqrt{\frac{\frac{0.75 e^{2}}{8 \pi \varepsilon_{0} a^{3}}-\frac{e^{2}}{8 \pi \varepsilon_{0}\left(a+c^{\prime}\right)^{3}}}{0.5 m_{p}}}
\end{array}\right]
$$

From the energy relationship given by Eq. (14.195) and the relationship between the axes given by Eqs. (14.192-14.193) and (14.62-14.63), the dimensions of the $H-H$ MO can be solved.

The most convenient way to solve Eq. (14.195) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is

$$
\begin{equation*}
a=5.7000 a_{0}=3.0163 \times 10^{-10} \mathrm{~m} \tag{14.196}
\end{equation*}
$$

Substitution of Eq. (14.196) into Eq. (14.192) gives:

$$
\begin{equation*}
c^{\prime}=1.6882 a_{0}=8.9335 \times 10^{-11} \mathrm{~m} \tag{14.197}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.197) by two is:

$$
\begin{equation*}
2 c^{\prime}=3.3764 a_{0}=1.7867 \times 10^{-10} \mathrm{~m} \tag{14.198}
\end{equation*}
$$

Substitution of Eqs. (14.196-14.197) into Eq. (14.62) gives:

$$
\begin{equation*}
b=c=5.4443 a_{0}=2.8810 \times 10^{-10} \mathrm{~m} \tag{14.199}
\end{equation*}
$$

Substitution of Eqs. (14.196-14.197) into Eq. (14.63) gives:

$$
\begin{equation*}
e=0.2962 \tag{14.200}
\end{equation*}
$$

From, $2 c_{H-H}^{\prime}$ (Eq. (14.198)), the distance between the two $H$ atoms when the total energy of the corresponding MO is zero (Eq. (14.195)), and $2 c_{C-H}^{\prime}$ (Eq. (14.179)), the internuclear distance of each $C-H$ bond, the corresponding bond angle can be determined from the law of cosines. Using, Eq. (13.242), the bond angle $\theta$ between the $C-H$ bonds is

$$
\begin{equation*}
\theta=\cos ^{-1}\left(\frac{2(2.09424)^{2}-(3.3764)^{2}}{2(2.09424)^{2}}\right)=\cos ^{-1}(-0.29964)=107.44^{\circ} \tag{14.201}
\end{equation*}
$$

The experimental angle between the $C-H$ bonds is [8]:

$$
\begin{equation*}
\theta=107.4^{\circ} \tag{14.202}
\end{equation*}
$$

The $\mathrm{CH}_{3}$ radical has a pyramidal structure with the carbon atom along the z -axis at the apex and the hydrogen atoms at the base in the xy-plane. The distance $d_{\text {origin-H }}$ from the origin to the nucleus of a hydrogen atom given by Eqs. (14.198) and (13.412) is:

$$
\begin{equation*}
d_{\text {origin }-H}=1.94936 a_{0} \tag{14.203}
\end{equation*}
$$

The height along the z-axis of the pyramid from the origin to $C$ nucleus $d_{\text {height }}$ given by Eqs. (13.414), (14.179), and (14.203) is

$$
\begin{equation*}
d_{\text {height }}=0.76540 a_{0} \tag{14.204}
\end{equation*}
$$

The angle $\theta_{v}$ of each $C-H$ bond from the z-axis given by Eqs. (13.416), (14.203), and (14.204) is:

$$
\begin{equation*}
\theta_{v}=68.563^{\circ} \tag{14.205}
\end{equation*}
$$

The $C-C$ bond is along the z-axis. Thus, the bond angle $\theta_{C-C-H}$ between the internuclear axis of the $C-C$ bond and a $H$ atom of the methyl groups is given by:

$$
\begin{equation*}
\theta_{C-C-H}=180-\theta_{v} \tag{14.206}
\end{equation*}
$$

Substitution of Eq. (14.205) into Eq. (14.206) gives:

$$
\begin{equation*}
\theta_{C-C-H}=111.44^{\circ} \tag{14.207}
\end{equation*}
$$

The experimental angle between the $C-C-H$ bonds is [3]:

$$
\begin{equation*}
\theta_{C-C-H}=111.17^{\circ} \tag{14.208}
\end{equation*}
$$

The $\mathrm{CH}_{3} \mathrm{CH}_{3} \mathrm{MO}$ shown in Figure 14.7 was rendered using these parameters. A minimum energy is obtained with a staggered configuration consistent with observations [3].

The charge-density in the $C-C$-bond MO is increased by a factor of 0.25 with the formation of the $C_{\text {ethane }} 2 s p^{3}$ HOs each having a smaller radius. Using the orbital composition of the $\mathrm{CH}_{3}$ groups (Eq. (14.173)) and the $\mathrm{C}-\mathrm{C}$-bond MO (Eq. (14.139)), the radii of $C 1 s=0.17113 a_{0}$ (Eq. (10.51)) and $C_{\text {ethane }} 2 s p^{3}=0.87495 a_{0}$ (Eq. (14.148)) shells, and the parameters of the $C-C$-bond (Eqs. (13.3-13.4), (14.158-14.160), and (14.162-14.172)), the parameters of the $C-H$-bond MOs (Eqs. (13.313.4), (14.177-14.179), and (14.181-14.191)), and the bond-angle parameters (Eqs. (14.195-14.208)), the charge-density of the $\mathrm{CH}_{3} \mathrm{CH}_{3} \mathrm{MO}$ comprising the linear combination of two sets of three $\mathrm{C}-\mathrm{H}$-bond MOs and a $\mathrm{C}-\mathrm{C}$-bond MO bridging the two methyl groups is shown in Figure 14.7. Each $\mathrm{C}-H$-bond MO comprises a $H_{2}$-type ellipsoidal MO and a $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$
having the dimensional diagram shown in Figure 14.6. The $C-C$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {ethane }} 2 s p^{3}$ HOs having the dimensional diagram shown in Figure 14.5.

Figure 14.7. $\mathrm{CH}_{3} \mathrm{CH}_{3} \mathrm{MO}$ comprising the linear combination of two sets of three $\mathrm{C}-\mathrm{H}$-bond MOs and a $\mathrm{C}-\mathrm{C}$-bond MO. (A) Color scale, translucent view of the charge-density of the $C-C$-bond MO with the $C_{\text {ethane }} 2 s p^{3}$ HOs shown transparently. The $C-C$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {ethane }} 2 s p^{3}$ HOs. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown. (B)-(D) End-on view, translucent view high-lighting the $C-C$-bond MO , and opaque view of the charge-density of the $\mathrm{CH}_{3} \mathrm{CH}_{3} \mathrm{MO}$, respectively.

## ENERGIES OF THE $\mathrm{CH}_{3}$ GROUPS

The energies of each $\mathrm{CH}_{3}$ group of ethane are given by the substitution of the semiprincipal axes (Eqs. (14.177-14.178) and (14.181)) into the energy equations of the methyl radical (Eqs. (13.556-13.560)), with the exception that $E\left(C_{\text {ethane }}, 2 s p^{3}\right)$ replaces $E\left(C, 2 s p^{3}\right)$ in Eq. (13.560):

$$
\begin{align*}
& V_{e}=3(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-107.68424 \mathrm{eV}  \tag{14.209}\\
& V_{p}=\frac{3 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=38.98068 \mathrm{eV}  \tag{14.210}\\
& T=3(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=32.73700 \mathrm{eV}  \tag{14.211}\\
& V_{m}=3(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-16.36850 \mathrm{eV}  \tag{14.212}\\
& E_{T_{\text {ehhane }}}\left(C H_{3}\right)=-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.35946 \mathrm{eV}=-67.69451 \mathrm{eV} \tag{14.213}
\end{align*}
$$

where $E_{T_{\text {elhane }}}\left(\mathrm{CH}_{3}\right)$ is given by Eq. (14.174) which is reiteratively matched to Eq. (13.542) within five-significant-figure round off error.

## VIBRATION OF THE ${ }^{12} \mathrm{CH}_{3}$ GROUPS

The vibrational energy levels of $\mathrm{CH}_{3}$ in ethane may be solved as three equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERMS OF THE ${ }^{12} \mathrm{CH}_{3}$ GROUPS

The equations of the radiation reaction force of the methyl groups in ethane are the same as those of the methyl radical with the substitution of the methyl-group parameters. Using Eq. (13.561), the angular frequency of the reentrant oscillation in the transition state is

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=2.50664 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{14.214}
\end{equation*}
$$

where $b$ is given by Eq. (14.181). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 2.50664 \times 10^{16} \mathrm{rad} / \mathrm{s}=16.49915 \mathrm{eV} \tag{14.215}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each $H_{2}$-type MO, for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.215) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-31.63537 \mathrm{eV} \sqrt{\frac{2 e(16.49915 \mathrm{eV})}{m_{e} c^{2}}}=-0.25422 \mathrm{eV} \tag{14.216}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of $\mathrm{CH}_{3}$ due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.216) and $\bar{E}_{K v i b}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of each $C-H$ bond. Using $\omega_{e}$ given by Eq. (13.458) for $\bar{E}_{\text {Kvib }}$ of the transition state having three independent bonds, $\bar{E}_{\text {ethane osc }}\left({ }^{12} \mathrm{CH}_{3}\right)$ per bond is:

$$
\begin{align*}
& \bar{E}_{\text {ethane osc }}^{\prime}\left({ }^{12} \mathrm{CH}_{3}\right)=\bar{E}_{D}+\bar{E}_{\text {Kvib }}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{14.217}\\
& \bar{E}_{\text {ehane asc }}^{\prime}\left({ }^{12} \mathrm{CH}_{3}\right)=-0.25422 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})=-0.07656 \mathrm{eV} \tag{14.218}
\end{align*}
$$

Given that the vibration and reentrant oscillation is for three $\mathrm{C}-\mathrm{H}$ bonds, $\bar{E}_{\text {ethane osc }}\left({ }^{12} \mathrm{CH}_{3}\right)$, is:

$$
\begin{equation*}
\bar{E}_{\text {ethane osc }}\left({ }^{12} \mathrm{CH}_{3}\right)=3\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)=3\left(-0.25422 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})\right)=-0.22967 \mathrm{eV} \tag{14.219}
\end{equation*}
$$

## TOTAL AND DIFFERENCE ENERGIES OF THE ${ }^{12} \mathrm{CH}_{3}$ GROUPS

$E_{\text {ethaneT }+ \text { osc }}\left({ }^{12} \mathrm{CH}_{3}\right)$, the total energy of each ${ }^{12} \mathrm{CH}_{3}$ group including the Doppler term, is given by the sum of $E_{T_{\text {ethane }}}\left(\mathrm{CH}_{3}\right)$ (Eq. (14.213)) and $\bar{E}_{\text {elhane osc }}\left({ }^{12} \mathrm{CH}_{3}\right)$ given by Eq. (14.219).

$$
\left.\begin{array}{rl}
E_{\text {ethaneT+osc }}\left({ }^{12} \mathrm{CH}_{3}\right) & =V_{e}+T+V_{m}+V_{p}+E\left(C_{\text {ethane }}, 2 s p^{3}\right)+\bar{E}_{\text {ethane osc }}\left({ }^{12} \mathrm{CH}_{3}\right) \\
& =E_{T_{\text {ethane }}}\left(\mathrm{CH}_{3}\right)+\bar{E}_{\text {ethane osc }}\left({ }^{12} \mathrm{CH}_{3}\right) \\
E_{\text {ethaneT oss }}\left({ }^{12} \mathrm{CH}_{3}\right) & =\left\{\begin{array}{l}
\left(\frac{-3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.359469 \mathrm{eV}\right) \\
-3\left((31.63536831 \mathrm{eV}) \sqrt{\frac{2 \hbar \sqrt{\frac{3}{4} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}}{m_{e}}}\right. \\
m_{e} c^{2}
\end{array}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)  \tag{14.221}\\
& =-67.69450 \mathrm{eV}-3\left(0.25422 \mathrm{eV}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{array}\right\}
$$

From Eqs. (14.217-14.221), the total energy of each ${ }^{12} \mathrm{CH}_{3}$ is:

$$
\begin{align*}
E_{\text {ehaneT } T \text { osc }}\left({ }^{12} \mathrm{CH}_{3}\right) & =-67.69450 \mathrm{eV}+\bar{E}_{\text {ehhane osc }}\left({ }^{12} \mathrm{CH}_{3}\right) \\
& =-67.69450 \mathrm{eV}-3\left(0.25422 \mathrm{eV}-\frac{1}{2}(0.35532 \mathrm{eV})\right)=-67.92417 \mathrm{eV} \tag{14.222}
\end{align*}
$$

where $\omega_{e}$ given by Eq. (13.458) was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The total energy for each methyl radical given by Eq. (13.569) is:

$$
\begin{align*}
E_{\text {radicalT osc }}\left({ }^{12} \mathrm{CH}_{3}\right) & =-67.69450 \mathrm{eV}+\bar{E}_{\text {radical osc }}\left({ }^{12} \mathrm{CH}_{3}\right) \\
& =-67.69450 \mathrm{eV}-3\left(0.25670 \mathrm{eV}-\frac{1}{2}(0.35532 \mathrm{eV})\right)=-67.93160 \mathrm{eV} \tag{14.223}
\end{align*}
$$

The difference in energy between the methyl groups and the methyl radical $\Delta E_{T+o s c}\left({ }^{12} \mathrm{CH}_{3}\right)$ is given by two times the difference between Eqs. (14.222) and (14.223):

$$
\begin{align*}
\Delta E_{T+o s c}\left({ }^{12} \mathrm{CH}_{3}\right) & =2\left(E_{\text {ethaneT Tosc }}\left({ }^{12} \mathrm{CH}_{3}\right)-E_{\text {radicalT }+ \text { osc }}\left({ }^{12} \mathrm{CH}_{3}\right)\right)  \tag{14.224}\\
& =2(-67.92417 \mathrm{eV}-(-67.93160 \mathrm{eV}))=0.01487 \mathrm{eV}
\end{align*}
$$

## SUM OF THE ENERGIES OF THE $C-C \sigma$ MO AND THE HOS OF ETHANE

The energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ of the $C-C$-bond MO are the same as those of the $C H$ MO as well as each $C-H$-bond MO of the methyl groups except that energy of the $C_{\text {ethane }} 2 s p^{3} \mathrm{HO}$ is used. The energies of each $C-C$-bond MO are given by the substitution of the semiprincipal axes (Eqs. (14.158-14.159) and (14.162)) into the energy equations of the CH MO (Eqs. (13.449-13.453)), with the exception that $E\left(C_{\text {ethane }}, 2 s p^{3}\right)$ replaces $E\left(C, 2 s p^{3}\right)$ in Eq. (13.453).

$$
\begin{align*}
& V_{e}=(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-29.101124 \mathrm{eV}  \tag{14.225}\\
& V_{p}=\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=9.37273 \mathrm{eV}  \tag{14.226}\\
& T=(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=6.90500 \mathrm{eV} \tag{14.227}
\end{align*}
$$

$$
\begin{align*}
& V_{m}=(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-3.45250 \mathrm{eV}  \tag{14.228}\\
& E_{T}(C-C, \sigma)=-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.35946 \mathrm{eV}=-31.63535 \mathrm{eV} \tag{14.229}
\end{align*}
$$

where $E_{T}(C-C, \sigma)$ is the total energy of the $C-C \sigma$ MO given by Eq. (14.155) which is reiteratively matched to Eq. (13.75) within five-significant-figure round off error.

The total energy of the $C-C$-bond MO, $E_{T}(C-C)$, is given by the sum of two times $E_{T}\left(C-C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell due to the decrease in radius with the formation of the $C-C$-bond MO (Eq. (14.151)), and $E_{T}(C-C, \sigma)$, the $\sigma \mathrm{MO}$ contribution given by Eq. (14.156).

$$
\begin{align*}
E_{T}(C-C) & =2 E_{T}\left(C-C, 2 s p^{3}\right)+E_{T}(C-C, \sigma) \\
& =\left(\begin{array}{l}
2(-0.72457 \mathrm{eV})+ \\
\left.\left(-\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a a_{0}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{a a_{0}}}{a-\sqrt{a a_{0}}}-1\right]-15.35946 \mathrm{eV}\right)\right) \\
\\
\end{array}\right) 2(-0.72457 \mathrm{eV})+(-31.63537 \mathrm{eV})=-33.08452 \mathrm{eV} \tag{14.230}
\end{align*}
$$

## VIBRATION OF ETHANE

The vibrational energy levels of $\mathrm{CH}_{3} \mathrm{CH}_{3}$ may be solved as two sets of three equivalent coupled harmonic oscillators with a bridging harmonic oscillator by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERMS OF THE $C-C$-BOND MO OF ETHANE

The equations of the radiation reaction force of the symmetrical $C-C$-bond MO are given by Eqs. (11.231-11.233), except the force-constant factor is 0.5 based on the force constant $k^{\prime}$ of Eq. (14.152), and the $C-C$-bond MO parameters are used. The angular frequency of the reentrant oscillation in the transition state is

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.5 e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}=9.55643 \times 10^{15} \mathrm{rad} / \mathrm{s} \tag{14.231}
\end{equation*}
$$

where $a$ is given by Eq. (14.158). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 9.55643 \times 10^{15} \mathrm{rad} / \mathrm{s}=6.29021 \mathrm{eV} \tag{14.232}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}(C-C)$ (Eq. (14.230)) for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.232) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-33.08450 \mathrm{eV} \sqrt{\frac{2 e(6.29021 \mathrm{eV})}{m_{e} c^{2}}}=-0.16416 \mathrm{eV} \tag{14.233}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $C-C$-bond MO due to the reentrant orbit of the bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.233) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of the $C-C$ bond. Using the experimental $C-C E_{v i b}\left(v_{3}\right)$ of $993 \mathrm{~cm}^{-1}(0.12312 \mathrm{eV})$ [10] for $\bar{E}_{\text {Kvib }}$ of the transition state, $\bar{E}_{\text {osc }}(C-C, \sigma)$ is:

$$
\begin{align*}
& \bar{E}_{\text {osc }}(C-C, \sigma)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{14.234}\\
& \bar{E}_{\text {osc }}(C-C, \sigma)=-0.16416 \mathrm{eV}+\frac{1}{2}(0.12312 \mathrm{eV})=-0.10260 \mathrm{eV} \tag{14.235}
\end{align*}
$$

## TOTAL ENERGIES OF THE $C-C$-BOND MO OF ETHANE

$E_{T+\text { osc }}(C-C)$, the total energy of the $C-C$-bond MO including the Doppler term, is given by the sum of $E_{T}(C-C)$ (Eq. (14.230)) and $\bar{E}_{\text {osc }}(C-C, \sigma)$ given by Eq. (14.235).

$$
\left.\left.\begin{array}{rl}
E_{T+o s c}(C-C)= & V_{e}+T+V_{m}+V_{p}+E\left(C_{\text {ethane }}, 2 s p^{3}\right)+2 E_{T}\left(C-C, 2 s p^{3}\right)+\bar{E}_{\text {osc }}(C-C, \sigma) \\
& =E_{T}(C-C, \sigma)+2 E_{T}\left(C-C, 2 s p^{3}\right)+\bar{E}_{\text {osc }}(C-C, \sigma)=E_{T}(C-C)+\bar{E}_{\text {osc }}(C-C, \sigma) \\
E_{T+o s c}(C-C)= & \left\{\binom{\left(\frac{-e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.35946 e V+2 E_{T}\left(C-C, 2 s p^{3}\right)\right)}{1+\sqrt{\frac{\frac{1}{2} \frac{e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}}+\frac{1}{m_{e} c^{2}} \hbar \sqrt{\frac{k}{\mu}}\right. \tag{14.237}
\end{array}\right)\right\}
$$

From Eqs. (14.234-14.237), the total energy of the $C-C$-bond MO is:

$$
\begin{align*}
E_{T+o s c}(C-C) & =-31.63537 \mathrm{eV}+2 E_{T}\left(C-C, 2 s p^{3}\right)+\bar{E}_{\text {osc }}(C-C, \sigma) \\
& =-31.63537 \mathrm{eV}+2(-0.72457 \mathrm{eV})-0.16416 \mathrm{eV}+\frac{1}{2}(0.12312 \mathrm{eV})=-33.18712 \mathrm{eV} \tag{14.238}
\end{align*}
$$

where the experimental $E_{v i b}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.

## BOND ENERGY OF THE $C-C$ BOND OF ETHANE

The dissociation energy of the $\mathrm{C}-\mathrm{C}$ bond of $\mathrm{CH}_{3} \mathrm{CH}_{3}, \mathrm{E}_{\mathrm{D}}\left(\mathrm{H}_{3} \mathrm{C}-\mathrm{CH}_{3}\right)$, is given by two times $\mathrm{E}\left(\mathrm{C}, 2 \mathrm{sp}{ }^{3}\right)$ (Eq. (14.146)), the initial energy of the $\mathrm{C} 2 s p^{3} \mathrm{HO}$ of each $\mathrm{CH}_{3}$ radical that bond with a single $\mathrm{C}-\mathrm{C}$ bond, minus the sum of $\Delta E_{T+\text { osc }}\left({ }^{12} \mathrm{CH}_{3}\right)$ (Eq. (14.224)), the energy change going from the methyl radicals to the methyl groups of ethane, and $E_{T+o s c}(C-C)$ (Eq. (14.238)). Thus, the dissociation energy of the $\mathrm{C}-\mathrm{C}$ bond of $\mathrm{CH}_{3} \mathrm{CH}_{3}$, is:

$$
\begin{align*}
E_{D}\left(\mathrm{H}_{3} \mathrm{C}-\mathrm{CH}_{3}\right) & =2\left(E\left(\mathrm{C}, 2 s p^{3}\right)\right)-\left(\Delta E_{T+o s c}\left({ }^{12} \mathrm{CH}_{3}\right)+E_{T+o s c}(\mathrm{C}-\mathrm{C})\right) \\
& =2(-14.63489 \mathrm{eV})-(0.01487 \mathrm{eV}-33.18712 \mathrm{eV})  \tag{14.239}\\
& =2(-14.63489 \mathrm{eV})-(33.17225 \mathrm{eV})=3.90247 \mathrm{eV}
\end{align*}
$$

The experimental dissociation energy of the $\mathrm{C}-\mathrm{C}$ bond of $\mathrm{CH}_{3} \mathrm{CH}_{3}$ is [6]:

$$
\begin{equation*}
E_{D}\left(\mathrm{H}_{3} \mathrm{C}-\mathrm{CH}_{3}\right)=3.89690 \mathrm{eV} \tag{14.240}
\end{equation*}
$$

The results of the determination of bond parameters of $\mathrm{CH}_{3} \mathrm{CH}_{3}$ are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## ETHYLENE MOLECULE ( $\mathrm{CH}_{2} \mathrm{CH}_{2}$ )

The ethylene molecule $\mathrm{CH}_{2} \mathrm{CH}_{2}$ is formed by the reaction of two dihydrogen carbide radicals:

$$
\begin{equation*}
\mathrm{CH}_{2}+\mathrm{CH}_{2} \rightarrow \mathrm{CH}_{2} \mathrm{CH}_{2} \tag{14.241}
\end{equation*}
$$

$\mathrm{CH}_{2} \mathrm{CH}_{2}$ can be solved using the same principles as those used to solve the methane series $\mathrm{CH}_{n=1,2,3,4}$, wherein the $2 s$ and $2 p$ shells of each $C$ hybridize to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. First, two sets of two $H$ atomic orbitals (AOs) combine with two sets of two carbon $2 s p^{3}$ HOs to form two dihydrogen carbide groups comprising a linear combination of four diatomic $H_{2}$-type MOs developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section. Then, the two $\mathrm{CH}_{2}$ groups bond by forming a $\mathrm{H}_{2}-$ type MO between the remaining two $C 2 s p^{3} \mathrm{HOs}$ on each carbon atom.

## FORCE BALANCE OF THE $C=C$-BOND MO OF ETHYLENE

$\mathrm{CH}_{2} \mathrm{CH}_{2}$ comprises a chemical bond between two $\mathrm{CH}_{2}$ radicals wherein each radical comprises two chemical bonds between carbon and hydrogen atoms. The solution of the parameters of $\mathrm{CH}_{2}$ is given in the Dihydrogen Carbide $\left(\mathrm{CH}_{2}\right)$ section. Each $\mathrm{C}-\mathrm{H}$ bond of $\mathrm{CH}_{2}$ having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of $75 \% H_{2}$-type ellipsoidal MO and $25 \% C 2 s p^{3} \mathrm{HO}$. The proton of the $H$ atom and the nucleus of the $C$ atom are along each internuclear axis and serve as the foci. As in the case of $H_{2}$, each of the two $C-H$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $C 2 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C 2 s p^{3}$ shell since it is energetically unfavorable. Thus, each MO surface comprises a prolate spheroid at the $H$ proton that is continuous with the $C 2 s p^{3}$ shell at the $C$ atom whose nucleus serves as the other focus. The electron configuration and the energy, $E\left(C, 2 s p^{3}\right)$, of the $C 2 s p^{3}$ shell is given by Eqs. (13.422) and (13.428), respectively. The central paramagnetic force due to spin of each $\mathrm{C}-\mathrm{H}$ bond is provided by the spin-pairing force of the $\mathrm{CH}_{2}$ MO that has the symmetry of an $s$ orbital that superimposes with the $C 2 s p^{3}$ orbitals such that the corresponding angular momenta are unchanged.

Two $\mathrm{CH}_{2}$ radicals bond to form $\mathrm{CH}_{2} \mathrm{CH}_{2}$ by forming a MO between the two pairs of remaining $\mathrm{C} 2 s p^{3}-\mathrm{HO}$ electrons of the two carbon atoms. However, in this case, the sharing of electrons between four $C 2 s p^{3}$ HOs to form a molecular orbital (MO) comprising four spin-paired electrons permits each $C 2 s p^{3} \mathrm{HO}$ to decrease in radius and energy.

As in the case of the $C-H$ bonds, the $C=C$-bond MO is a prolate-spheroidal-MO surface that cannot extend into $C 2 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C 2 s p^{3}$ shell of each atom. Thus, the MO surface comprises a partial prolate spheroid in between the carbon nuclei and is continuous with the $C 2 s p^{3}$ shell at each $C$ atom. The energy of the $H_{2}$ type ellipsoidal MO is matched to that of the $C 2 s p^{3}$ shell. As in the case of previous examples of energy-matched MOs such as those of $\mathrm{OH}, \mathrm{NH}, \mathrm{CH}$, the $\mathrm{C}=\mathrm{O}$-bond MO of $\mathrm{CO}_{2}$, and the $\mathrm{C}-\mathrm{C}$-bond MO of $\mathrm{CH}_{3} \mathrm{CH}_{3}$, the $\mathrm{C}=\mathrm{C}$-bond MO of ethylene must comprise $75 \%$ of a $H_{2}$-type ellipsoidal MO in order to match potential, kinetic, and orbital energy relationships. Thus, the $C=C$-bond MO must comprise a linear combination of two MOs wherein each comprises two $C 2 s p^{3} \mathrm{HOs}$ and $75 \%$ of a $\mathrm{H}_{2}$ type ellipsoidal MO divided between the $C 2 s p^{3} \mathrm{HOs}$ :

$$
\begin{equation*}
2\left(2 \mathrm{C} 2 s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO}\right) \rightarrow \mathrm{C}=\mathrm{C}-\text { bond } \mathrm{MO} \tag{14.242}
\end{equation*}
$$

The linear combination of each $H_{2}$-type ellipsoidal MO with each $C 2 s p^{3} \mathrm{HO}$ further comprises an excess $25 \%$ charge-density contribution from each $C 2 s p^{3} \mathrm{HO}$ to the $C=C$-bond MO to achieve an energy minimum. The force balance of the $C=C$ bond MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.242) and the energy matching condition between the $C 2 s p^{3}-\mathrm{HO}$ components of the MO.

Similarly, the energies of each $\mathrm{CH}_{2}$ MO involve each $\mathrm{C} 2 s p^{3}$ and each $\mathrm{H} 1 s$ electron with the formation of each $\mathrm{C}-\mathrm{H}$ bond. The sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $C 2 s p^{3}$ shell. This energy is determined by the considering the effect of the donation of $25 \%$ electron density from the two pairs of $C 2 s p^{3} \mathrm{HOs}$ to the $C=C$-bond MO with the formation of the $C_{\text {ethylene }} 2 s p^{3}$ HOs each having a smaller radius. The $2 s p^{3}$ hybridized orbital arrangement is given by Eq. (14.140). The sum $E_{T}\left(C, 2 s p^{3}\right)$ of calculated energies of $C, C^{+}, C^{2+}$, and $C^{3+}$ is given by Eq. (14.141). The radius $r_{2 s p^{3}}$ of the $C 2 s p^{3}$ shell is given by Eq. (14.142). The Coulombic energy $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ and the energy $E\left(C, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell are given by Eqs. (14.143) and (14.146), respectively.

Next, consider the formation of the $\mathrm{C}=\mathrm{C}$-bond MO of ethylene from two $\mathrm{CH}_{2}$ radicals, each having a $\mathrm{C} 2 s p^{3}$ electron with an energy given by Eq. (14.146). The total energy of the state is given by the sum over the four electrons. The sum $E_{T}\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ of calculated energies of $C 2 s p^{3}, C^{+}, C^{2+}$, and $C^{3+}$ from Eqs. (10.123), (10.113-10.114), (10.68), and (10.48), respectively, is:

$$
\begin{align*}
E_{T}\left(C_{\text {ethylene }}, 2 s p^{3}\right) & =-\left(64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+E\left(C, 2 s p^{3}\right)\right) \\
& =-(64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+14.63489 \mathrm{eV})  \tag{14.243}\\
& =-151.61569 \mathrm{eV}
\end{align*}
$$

where $E\left(C, 2 s p^{3}\right)$ (Eq. (14.146)) is the sum of the energy of $C,-11.27671 \mathrm{eV}$, and the hybridization energy. The orbital-angular-momentum interactions also cancel such that the energy of the $E_{T}\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ is purely Coulombic.

The sharing of electrons between two pairs of $C 2 s p^{3} \mathrm{HOs}$ to form a $C=C$-bond MO permits each participating hybridized orbital to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each participating $C 2 s p^{3} \mathrm{HO}$ donates an excess of $25 \%$ per bond of its electron density to the $C=C$-bond MO to form an energy minimum. By considering this electron redistribution in the ethylene molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{\text {ethylene } s p^{3}}$ of the $C 2 s p^{3}$ shell of ethylene may be calculated from the Coulombic energy using Eq. (10.102).

$$
\begin{equation*}
r_{\text {ethylene } 2 s p^{3}}=\left(\sum_{n=2}^{5}(Z-n)-0.5\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 151.61569 \mathrm{eV})}=\frac{9.5 e^{2}}{8 \pi \varepsilon_{0}(\mathrm{e} 151.61569 \mathrm{eV})}=0.85252 a_{0} \tag{14.244}
\end{equation*}
$$

where $Z=6$ for carbon. Using Eqs. (10.102) and (14.244), the Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(C_{\text {ethylene }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {ethylene2sp }}{ }^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.85252 a_{0}}=-15.95955 \mathrm{eV} \tag{14.245}
\end{equation*}
$$

During hybridization, the spin-paired $2 s$ electrons are promoted to the $C 2 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (13.152). Using Eqs. (14.145) and (14.245), the energy $E\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is

$$
\begin{equation*}
E\left(C_{\text {ethylene }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {ethylene } 2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-15.95955 \mathrm{eV}+0.19086 \mathrm{eV}=-15.76868 \mathrm{eV} \tag{14.246}
\end{equation*}
$$

Thus, $E_{T}\left(C=C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell with the formation of the $C=C$-bond MO is given by the difference between Eq. (14.146) and Eq. (14.246):

$$
\begin{equation*}
E_{T}\left(C=C, 2 s p^{3}\right)=E\left(C_{\text {ethylene }}, 2 s p^{3}\right)-E\left(C, 2 s p^{3}\right)=-15.76868 \mathrm{eV}-(-14.63489 \mathrm{eV})=-1.13380 \mathrm{eV} \tag{14.247}
\end{equation*}
$$

As in the case of $\mathrm{Cl}_{2}$, each $\mathrm{H}_{2}$-type ellipsoidal MO comprises $75 \%$ of the $\mathrm{C}=\mathrm{C}$-bond MO shared between two $C 2 s p^{3}$ HOs corresponding to the electron charge density in Eq. (11.65) of $\frac{-0.75 e}{2}$. But, the additional $25 \%$ charge-density contribution to each bond of the $C=C$-bond MO causes the electron charge density in Eq. (11.65) to be $\frac{-e}{2}=-0.5 e$. The corresponding force constant $k^{\prime}$ is given by Eq. (14.152). In addition, the energy matching at both $C 2 s p^{3}$ HOs further requires that $k^{\prime}$ be corrected by the hybridization factor given by Eq. (13.430). Thus, the force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ in terms of the central force of the foci (Eq. (11.65)) is given by:

$$
\begin{equation*}
k^{\prime}=C_{C 2 s p^{3} H O} \frac{(0.5) 2 e^{2}}{4 \pi \varepsilon_{0}}=0.91771 \frac{(0.5) 2 e^{2}}{4 \pi \varepsilon_{0}} \tag{14.248}
\end{equation*}
$$

The distance from the origin to each focus $c^{\prime}$ is given by substitution of Eq. (14.248) into Eq. (13.60). Thus, the distance from the origin of the component of the double $C=C$-bond MO to each focus $c^{\prime}$ is given by:

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{(0.91771) m_{e} e^{2} a}}=\sqrt{\frac{a a_{0}}{0.91771}} \tag{14.249}
\end{equation*}
$$

The internuclear distance from Eq. (14.249) is:

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{\frac{a a_{0}}{0.91771}} \tag{14.250}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal $C=C$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of the $C=C$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the $C=C$-bond MO are solved.

The general equations for the energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ of the $C=C$-bond MO are the same as those of the $C H$ MO except that energy of the $C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}$ is used and the double-bond nature is considered. In the case of a single bond, the prolate spheroidal $H_{2}$-type MO transitions to the $C_{\text {ehylene }} 2 s p^{3} \mathrm{HO}$ of each carbon, and the energy of the $C_{\text {ethylene }} 2 s p^{3}$ shell must remain constant and equal to the $E\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ given by Eq. (14.246). Thus, the energy $E\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ in Eq. (14.246) adds to that of the energies of the corresponding $H_{2}$-type ellipsoidal MO. The second bond of the double $C=C$-bond MO also transitions to the $C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}$ of each $C$. The energy of a second $H_{2}$-type ellipsoidal MO
adds to the first energy component, and the two bonds achieve an energy minimum as a linear combination of the two $H_{2}$-type ellipsoidal MOs each having the carbon nuclei as the foci. Each $C-C$-bond MO comprises the same $C_{\text {ethylene }} 2 s p^{3}$ HO shells of constant energy given by Eq. (14.246). As in the case of the water, $\mathrm{NH}_{2}$, and ammonia molecules given by Eqs. (13.180), (13.320), and (13.372), respectively, the energy of the redundant shell is subtracted from the total energy of the linear combination of the $\sigma$ MO. Thus, the total energy $E_{T}(C=C, \sigma)$ of the $\sigma$ component of the $C=C$-bond MO is given by the sum of the energies of the two bonds each comprising the linear combination of the $C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}$ and the $H_{2}$-type ellipsoidal MO as given by Eq. (14.242) wherein the $E_{T}$ terms add positively, the $E\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ terms cancel, and the energy matching condition between the components is provided by Eq. (14.248). Using Eqs. (13.431) and (14.246), $E_{T}(C=C, \sigma)$ is given by:

$$
\begin{align*}
E_{T}(C=C, \sigma) & =E_{T}+E\left(C_{\text {ethylene }}, 2 s p^{3}\right)-E\left(C_{\text {ethylene }}, 2 s p^{3}\right) \\
& =-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right] \tag{14.251}
\end{align*}
$$

The total energy term of the double $C=C$-bond MO is given by the sum of the two $H_{2}$-type ellipsoidal MOs given by Eq. (11.212). To match this boundary condition, $E_{T}(C=C, \sigma)$ given by Eq. (14.251) is set equal to two times Eq. (13.75).

$$
\begin{equation*}
E_{T}(C=C, \sigma)=-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]=-63.27074 \mathrm{eV} \tag{14.252}
\end{equation*}
$$

From the energy relationship given by Eq. (14.252) and the relationship between the axes given by Eqs. (14.249-14.250) and (13.62-13.63), the dimensions of the $C=C$-bond MO can be solved.

> Substitution of Eq. (14.249) into Eq. (14.252) gives:

$$
\begin{equation*}
\frac{2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{0.91771}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{0.91771}}}{a-\sqrt{\frac{a a_{0}}{0.91771}}}-1\right]=e 63.27074 \tag{14.253}
\end{equation*}
$$

The most convenient way to solve Eq. (14.253) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is:

$$
\begin{equation*}
a=1.47228 a_{0}=7.79098 \times 10^{-11} \mathrm{~m} \tag{14.254}
\end{equation*}
$$

Substitution of Eq. (14.254) into Eq. (14.249) gives

$$
\begin{equation*}
c^{\prime}=1.26661 a_{0}=6.70259 \times 10^{-11} \mathrm{~m} \tag{14.255}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.255) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.53321 a_{0}=1.34052 \times 10^{-10} \mathrm{~m} \tag{14.256}
\end{equation*}
$$

The experimental bond distance is [3]:

$$
\begin{equation*}
2 c^{\prime}=1.339 \times 10^{-10} \mathrm{~m} \tag{14.257}
\end{equation*}
$$

Substitution of Eqs. (14.254-14.255) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=0.75055 a_{0}=3.97173 \times 10^{-11} \mathrm{~m} \tag{14.258}
\end{equation*}
$$

Substitution of Eqs. (14.252-14.255) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.86030 \tag{14.259}
\end{equation*}
$$

The nucleus of the $C$ atoms comprise the foci of the $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{\text {ethylene2sp }}{ }^{3}=0.85252 a_{0}$ is the radius of the $C_{\text {ethylene }} 2 s p^{3}$ shell. Substitution of Eqs. (14.254-14.255) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=129.84^{\circ} \tag{14.260}
\end{equation*}
$$

Then, the angle $\theta_{C=C_{\text {ethylene }} 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C=C_{\text {ethylene }} 2 s p^{3} H O}=180^{\circ}-129.84^{\circ}=50.16^{\circ} \tag{14.261}
\end{equation*}
$$

as shown in Figure 14.8.

Figure 14.8. The cross section of the $C=C$-bond $\mathrm{MO}(\sigma \mathrm{MO})$ and one $C-H$-bond MO of ethylene showing the axes, angles, and point of intersection of each $H_{2}$-type ellipsoidal MO with the corresponding $C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}$. The continuation of each $H_{2}$-type-ellipsoidal-MO basis element of the $C=C$ bond and the $C-H$-bond beyond the intersection point with each $C_{\text {ethylene }} 2 s p^{3}$ shell and $\sigma$ MO is shown as dashed since each only serves to solve the energy match with the $C_{\text {ethylene }} 2 s p^{3}$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of each intersection point. The actual charge density is shown by the solid lines. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $d_{1}: d_{C=C_{\text {ethylene }}, H_{2} M O}, \quad \theta_{1}: \theta_{C=C_{\text {ethylene }} 2 s p^{3} H O}, d_{2}: d_{C=C_{\text {ethylene }} 2 s p^{3} H O}, R: r_{\text {ethyleneC } 2 s p^{3}}, d_{3}: d_{C-H_{\text {ethylene }}, H_{2} M O}, \theta_{2}: \theta_{C-H_{\text {ethylene }} 2 s p^{3} H O}$, and $d_{4}: d_{C-H_{\text {ethylene }} 2 s p^{3} H O}$.

Consider the right-hand intersection point. The Cartesian i-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$ coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{C=C_{\text {ehhylene }}, H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{\text {ethylene 2sp3 }}{ }^{3} \sin \theta_{C=C_{\text {ethylene }} 2 s p^{3} H O}=0.85252 a_{0} \sin \theta_{C=C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}}=b \sin \theta_{C=C_{\text {ethylene }}, H_{2} M O} \tag{14.262}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{C=C_{\text {ethylene }}, H_{2} M O}=\sin ^{-1} \frac{0.85252 a_{0} \sin \theta_{C=C_{\text {ethylene }} 2 s p^{3} H O}}{b}=\sin ^{-1} \frac{0.85252 a_{0} \sin 50.16^{\circ}}{b} \tag{14.263}
\end{equation*}
$$

with the use of Eq. (14.261). Substitution of Eq. (14.258) into Eq. (14.263) gives:

$$
\begin{equation*}
\theta_{C=C_{\text {ethylene }}, H_{2} M O}=60.70^{\circ} \tag{14.264}
\end{equation*}
$$

Then, the distance $d_{C=C_{\text {ethylene }}, H_{2} M O}$ along the internuclear axis from the origin of $H_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C=C_{\text {ehlylene }}, H_{2} M O}=a \cos \theta_{C=C_{\text {ethylene }}, H_{2} M O} \tag{14.265}
\end{equation*}
$$

Substitution of Eqs. (14.254) and (14.264) into Eq. (14.265) gives:

$$
\begin{equation*}
d_{C=C_{\text {ethylene }}, H_{2} M O}=0.72040 a_{0}=3.81221 \times 10^{-11} \mathrm{~m} \tag{14.266}
\end{equation*}
$$

The distance $d_{C=C_{\text {ethylene }} 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C=C_{\text {ehylene }} 2 s p^{3} H O}=c^{\prime}-d_{C=C_{\text {ethylene }}, H_{2} M O} \tag{14.267}
\end{equation*}
$$

Substitution of Eqs. (14.255) and (14.266) into Eq. (14.267) gives:

$$
\begin{equation*}
d_{C=C_{\text {ethylene }} 2 s p^{3} H O}=0.54620 a_{0}=2.89038 \times 10^{-11} \mathrm{~m} \tag{14.268}
\end{equation*}
$$

## FORCE BALANCE OF THE $\mathrm{CH}_{2}$ MOS OF ETHYLENE

Each of the two equivalent $\mathrm{CH}_{2}$ MOs must comprise two $\mathrm{C}-\mathrm{H}$ bonds with each comprising $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO and a $C 2 s p^{3} \mathrm{HO}$ as given by Eq. (13.494):

$$
\begin{equation*}
2\left[1{\mathrm{C} 2 s p^{3}}^{3}+0.75 \mathrm{H}_{2} \mathrm{MO}\right] \rightarrow \mathrm{CH}_{2} \mathrm{MO} \tag{14.269}
\end{equation*}
$$

The force balance of the $\mathrm{CH}_{2} \mathrm{MO}$ is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.494) and the energy matching condition between the hydrogen and $C 2 s p^{3} \mathrm{HO}$ components of the MO.

The force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ of each $\mathrm{H}_{2}$-type-ellipsoidal-MO component of the $\mathrm{CH}_{2}$ MO in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus $c^{\prime}$ is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $C-H$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the $\mathrm{CH}_{2} \mathrm{MO}$ are solved.

Consider the formation of the double $C=C$-bond MO of ethylene from two $\mathrm{CH}_{2}$ radicals, each having a $\mathrm{C} 2 s p^{3}$ shell with an energy given by Eq. (14.146). The energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ are the same as those of the dihydrogen carbide radical, two times those of $C H$ corresponding to the two $C-H$ bonds, except that two times $E_{T}\left(C=C, 2 s p^{3}\right)$ is subtracted from $E_{T}\left(\mathrm{CH}_{2}\right)$ of Eq. (13.495). The subtraction of the energy change of the $C 2 s p^{3}$ shells with the formation of the $C=C$-bond MO matches the energy of the $C-H$-bond MOs to the decrease in the energy of the $C 2 s p^{3}$ HOs. Using Eqs. (13.495) and (14.247), $E_{T_{\text {cllyberee }}}\left(\mathrm{CH}_{2}\right)$ is given by:

$$
\begin{equation*}
E_{T_{\text {elthylene }}}\left(C H_{2}\right)=E_{T}+E\left(C, 2 s p^{3}\right)-2 E_{T}\left(C=C, 2 s p^{3}\right)=\binom{-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]}{-14.63489 \mathrm{eV}-(-2.26758 \mathrm{eV})} \tag{14.270}
\end{equation*}
$$

$E_{T_{\text {ethylene }}}\left(\mathrm{CH}_{2}\right)$ given by Eq. (14.270) is set equal to two times the energy of the $H_{2}$-type ellipsoidal MO minus the Coulombic energy of $H$ given by Eq. (13.496):

$$
\begin{equation*}
E_{T_{\text {elhylene }}}\left(C H_{2}\right)=\binom{-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]}{-14.63489 \mathrm{eV}-(-2.26758 \mathrm{eV})}=-49.66493 \mathrm{eV} \tag{14.271}
\end{equation*}
$$

From the energy relationship given by Eq. (14.271) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the $\mathrm{CH}_{2} \mathrm{MO}$ can be solved.

> Substitution of Eq. (13.60) into Eq. (14.271) gives:

$$
\begin{equation*}
\frac{2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right]=e 37.29762 \tag{14.272}
\end{equation*}
$$

The most convenient way to solve Eq. (14.272) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is:

$$
\begin{equation*}
a=1.56946 a_{0}=8.30521 \times 10^{-11} \mathrm{~m} \tag{14.273}
\end{equation*}
$$

Substitution of Eq. (14.273) into Eq. (13.60) gives:

$$
\begin{equation*}
c^{\prime}=1.02289 a_{0}=5.41290 \times 10^{-11} \mathrm{~m} \tag{14.274}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.274) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.04578 a_{0}=1.08258 \times 10^{-10} \mathrm{~m} \tag{14.275}
\end{equation*}
$$

The experimental bond distance is [3]:

$$
\begin{equation*}
2 c^{\prime}=1.087 \times 10^{-10} \mathrm{~m} \tag{14.276}
\end{equation*}
$$

Substitution of Eqs. (14.273-14.274) into Eq. (14.62) gives:

$$
\begin{equation*}
b=c=1.19033 a_{0}=6.29897 \times 10^{-11} \mathrm{~m} \tag{14.277}
\end{equation*}
$$

Substitution of Eqs. (14.273-14.274) into Eq. (14.63) gives:

$$
\begin{equation*}
e=0.65175 \tag{14.278}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $C$ atom comprise the foci of each $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95)
and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{\text {ethylene2sp }}=0.85252 a_{0}$ is the radius of the $C_{\text {etthylene }} 2 s p^{3}$ shell. Substitution of Eqs. (14.273-14.274) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=84.81^{\circ} \tag{14.279}
\end{equation*}
$$

Then, the angle $\theta_{C-H_{\text {ethylene }} 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C-H_{\text {ethylene }} 2 s p^{3} H O}=180^{\circ}-84.81^{\circ}=95.19^{\circ} \tag{14.280}
\end{equation*}
$$

as shown in Figure 14.9.
Figure 14.9. The cross section of one $C-H$-bond MO of ethylene showing the axes, angles, and point of intersection of the $H_{2}$-type ellipsoidal MO with the $C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}$. The continuation of the $H_{2}$-type-ellipsoidal-MO basis element beyond the intersection point with the $C_{\text {ethylene }} 2 s p^{3}$ shell is shown as dashed since it only serves to solve the energy match with the $C_{\text {ethylene }} 2 s p^{3}$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of the intersection point. The actual charge density is shown by the solid lines. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $d_{1}: d_{C-H_{\text {ethylene }}, H_{2} M O}, \theta_{1}: \theta_{C-H_{\text {ethylene }} 2 s p^{3} H O}, d_{2}: d_{C-H_{\text {ethylene }} 2 s p^{3} H O}$, and $R: r_{\text {ethylene } 2 s p^{3}}$.

The Cartesian i-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{C-H_{\text {ethylene }}, H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{\text {ethylene } 2 s p^{3}} \sin \theta_{C-H_{\text {ethylene }} 2 s p^{3} H O}=0.85252 a_{0} \sin \theta_{C-H_{\text {ethylene }} 2 s p^{3} H O}=b \sin \theta_{C-H, H_{2} M O} \tag{14.281}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{C-H_{\text {ethylene }}, H_{2} M O}=\sin ^{-1} \frac{0.85252 a_{0} \sin \theta_{C-H_{\text {ethylene }} 2 s p^{3} H O}}{b}=\sin ^{-1} \frac{0.85252 a_{0} \sin 95.19^{\circ}}{b} \tag{14.282}
\end{equation*}
$$

with the use of Eq. (14.280). Substitution of Eq. (14.277) into Eq. (14.282) gives:

$$
\begin{equation*}
\theta_{C-H_{\text {ethylene }}, H_{2} M O}=45.50^{\circ} \tag{14.283}
\end{equation*}
$$

Then, the distance $d_{C-H_{\text {ethylene }}, H_{2} M O}$ along the internuclear axis from the origin of $H_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C-H_{\text {ethylene }}, H_{2} M O}=a \cos \theta_{C-H_{\text {ethylene }}, H_{2} M O} \tag{14.284}
\end{equation*}
$$

Substitution of Eqs. (14.273) and (14.283) into Eq. (14.284) gives:

$$
\begin{equation*}
d_{C-H_{\text {ethylene }}, H_{2} M O}=1.10002 a_{0}=5.82107 \times 10^{-11} \mathrm{~m} \tag{14.285}
\end{equation*}
$$

The distance $d_{C-H_{\text {ethylene }} 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C-H_{\text {ethylene }} 2 s p^{3} \mathrm{HO}}=d_{C-\mathrm{H}_{\text {ehylene },}, \mathrm{H}_{2} \mathrm{MO}}-c^{\prime} \tag{14.286}
\end{equation*}
$$

Substitution of Eqs. (14.274) and (14.285) into Eq. (14.286) gives:

$$
\begin{equation*}
d_{C-H_{\text {ethylene }} 2 s p^{3} H O}=0.07713 a_{0}=4.08171 \times 10^{-12} \mathrm{~m} \tag{14.287}
\end{equation*}
$$

## BOND ANGLE OF THE $\mathrm{CH}_{2}$ GROUPS

Each $\mathrm{CH}_{2}$ MO comprises a linear combination of two $\mathrm{C}-\mathrm{H}$-bond MOs. Each $\mathrm{C}-\mathrm{H}$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and the $C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}$. A bond is also possible between the two H atoms of the $C-H$ bonds. Such $H-H$ bonding would decrease the $C-H$ bond strength since electron density would be shifted from the $C-H$ bonds to the $H-H$ bond. Thus, the bond angle between the two $C-H$ bonds is determined by the condition that the total energy of the $H_{2}$-type ellipsoidal MO between the terminal $H$ atoms of the $C-H$ bonds is zero. From Eqs. (11.79) and (13.228), the distance from the origin to each focus of the $H-H$ ellipsoidal MO is:

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 2 a}}=\sqrt{\frac{a a_{0}}{2}} \tag{14.288}
\end{equation*}
$$

The internuclear distance from Eq. (13.229) is:

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{\frac{a a_{0}}{2}} \tag{14.289}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal $H-H$ MO $b=c$ is given by Eq. (14.62).
The bond angle of the $\mathrm{CH}_{2}$ groups of ethane is derived by using the orbital composition and an energy matching factor as in the case with the dihydrogen carbide radical and the $\mathrm{CH}_{3}$ groups of ethane. Since the two $\mathrm{H}_{2}$-type ellipsoidal MOs initially comprise $75 \%$ of the $H$ electron density of $H_{2}$ and the energy of each $H_{2}$-type ellipsoidal MO is matched to that of the $C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}$, the component energies and the total energy $E_{T}$ of the $H-H$ bond are given by Eqs. (13.67-13.73) except that $V_{e}, T$, and $V_{m}$ are corrected for the hybridization-energy-matching factor of 0.85252 . Hybridization with $25 \%$ electron donation to the $C=C$-bond gives rise to the $C_{\text {ethylene }} 2 s p^{3}$ HO-shell Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ given by Eq. (14.245). The corresponding normalization factor for determining the zero of the total $H-H$ bond energy is given by the ratio of 15.95955 eV , the magnitude of $E_{\text {Coulomb }}\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ given by Eq. (14.245), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). The hybridization energy factor $C_{\text {ethylenec2sp }{ }^{3} H O}$ is:

$$
\begin{equation*}
C_{\text {ethylenec } 2 \text { sp } 3 \text { 3 } H O}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} r_{\text {ethylene } 2 s p^{3}}}}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} 0.85252 a_{0}}}=\frac{13.605804 \mathrm{eV}}{15.95955 \mathrm{eV}}=0.85252 \tag{14.290}
\end{equation*}
$$

Substitution of Eq. (14.290) into Eq. (13.233) or Eq. (14.195) with the hybridization factor of 0.85252 gives:

$$
0=\left[\begin{array}{l}
\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left[(0.85252)^{-1}\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right]\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}}{m_{e} c^{2}}}\right]  \tag{14.291}\\
+\hbar \sqrt{\frac{\frac{0.75 e^{2}}{\frac{8 \pi \varepsilon_{0} a^{3}}{}}-\frac{e^{2}}{8 \pi \varepsilon_{0}\left(a+c^{\prime}\right)^{3}}}{0.5 m_{p}}}
\end{array}\right]
$$

From the energy relationship given by Eq. (14.291) and the relationship between the axes given by Eqs. (14.192-14.193) and (14.62-14.63), the dimensions of the $H-H$ MO can be solved.

The most convenient way to solve Eq. (14.291) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a=6.0400 a_{0}=3.1962 \times 10^{-10} \mathrm{~m} \tag{14.292}
\end{equation*}
$$

Substitution of Eq. (14.292) into Eq. (14.288) gives:

$$
\begin{equation*}
c^{\prime}=1.7378 a_{0}=9.1961 \times 10^{-11} \mathrm{~m} \tag{14.293}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.293) by two is:

$$
\begin{equation*}
2 c^{\prime}=3.4756 a_{0}=1.8392 \times 10^{-10} \mathrm{~m} \tag{14.294}
\end{equation*}
$$

Substitution of Eqs. (14.292-14.293) into Eq. (14.62) gives:

$$
\begin{equation*}
b=c=5.7846 a_{0}=3.0611 \times 10^{-10} \mathrm{~m} \tag{14.295}
\end{equation*}
$$

Substitution of Eqs. (14.292-14.293) into Eq. (14.63) gives:

$$
\begin{equation*}
e=0.2877 \tag{14.296}
\end{equation*}
$$

From, $2 c_{H-H}^{\prime}$ (Eq. (14.294)), the distance between the two $H$ atoms when the total energy of the corresponding MO is zero (Eq. (14.291)), and $2 c_{C-H}^{\prime}$ (Eq. (14.275)), the internuclear distance of each $C-H$ bond, the corresponding bond angle can be determined from the law of cosines. Using, Eq. (13.242), the bond angle $\theta_{H C H}$ between the $C-H$ bonds is:

$$
\begin{equation*}
\theta_{H C H}=\cos ^{-1}\left(\frac{2(2.04578)^{2}-(3.4756)^{2}}{2(2.04578)^{2}}\right)=\cos ^{-1}(-0.44318)=116.31^{\circ} \tag{14.297}
\end{equation*}
$$

The experimental angle between the $C-H$ bonds is [11]:

$$
\begin{equation*}
\theta_{H C H}=116.6^{\circ} \tag{14.298}
\end{equation*}
$$

The $C=C$ bond is along the z-axis. Thus, based on the symmetry of the equivalent bonds, the bond angle $\theta_{C=C-H}$ between the internuclear axis of the $\mathrm{C}=\mathrm{C}$ bond and a H atom of the $\mathrm{CH}_{2}$ groups is given by:

$$
\begin{equation*}
\theta_{C=C-H}=\frac{\left(360^{\circ}-\theta_{H C H}\right)}{2} \tag{14.299}
\end{equation*}
$$

Substitution of Eq. (14.298) into Eq. (14.299) gives:

$$
\begin{equation*}
\theta_{C=C-H}=121.85^{\circ} \tag{14.300}
\end{equation*}
$$

The experimental angle between the $C=C-H$ bonds is [11]:

$$
\begin{equation*}
\theta_{C=C-H}=121.7^{\circ} \tag{14.301}
\end{equation*}
$$

and [3]

$$
\begin{equation*}
\theta_{C=C-H}=121.3^{\circ} \tag{14.302}
\end{equation*}
$$

The $C=C$ bond and $H$ atoms of ethylene line in a plane, and rotation about the $C=C$ is not possible due to conservation of angular momentum in the two sets of spin-paired electrons of the double bond. The $\mathrm{CH}_{2} \mathrm{CH}_{2}$ MO shown in Figure 14.10 was rendered using these parameters.

The charge-density in the $C=C$-bond MO is increased by a factor of 0.25 per bond with the formation of the $C_{\text {ethylene }} 2 s p^{3}$ HOs each having a smaller radius. Using the orbital composition of the $\mathrm{CH}_{2}$ groups (Eq. (14.269)) and the $C=C$ bond MO (Eq. (14.242)), the radii of $C 1 s=0.17113 a_{0}$ (Eq. (10.51)) and $C_{\text {ethylene }} 2 s p^{3}=0.85252 a_{0}$ (Eq. (14.244)) shells, and the parameters of the $C=C$-bond (Eqs. (13.3-13.4), (14.254-14.256), and (14.258-14.268)), the parameters of the $C-H$-bond MOs (Eqs. (13.3-13.4), (14.273-14.275), and (14.277-14.287)), and the bond-angle parameters (Eqs. (14.297-14.302)), the charge-density of the $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{MO}$ comprising the linear combination of two sets of two $\mathrm{C}-\mathrm{H}$-bond MOs and a $\mathrm{C}=\mathrm{C}$-bond MO bridging the two $\mathrm{CH}_{2}$ groups is shown in Figure 14.10. Each $\mathrm{C}-\mathrm{H}$-bond MO comprises a $\mathrm{H}_{2}$-type ellipsoidal MO and a $C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}$ having the dimensional diagram shown in Figure 14.9. The $C=C$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {ethylene }} 2 s p^{3}$ HOs having the dimensional diagram shown in Figure 14.8.

Figure 14.10. $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{MO}$ comprising the linear combination of two sets of two $\mathrm{C}-H$-bond MOs and a $C=C$-bond MO. (A) Color scale, translucent view of the charge-density of the $C=C$-bond MO with the $C_{\text {ethylene }} 2 s p^{3}$ HOs shown transparently. The $C=C$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two sets of two $C_{\text {ethylene }} 2 s p^{3}$ HOs. For each $C-H$ and the $C=C$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {ethylene }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown. (B)-(D) End-on view, translucent view high-lighting the $\mathrm{C}=\mathrm{C}$-bond MO , and opaque view of the charge-density of the $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{MO}$, respectively.

## ENERGIES OF THE $\mathrm{CH}_{2}$ GROUPS

The energies of each $\mathrm{CH}_{2}$ group of ethylene are given by the substitution of the semiprincipal axes (Eqs. (14.273-14.274) and (14.277)) into the energy equations of dihydrogen carbide (Eqs. (13.510-13.514)), with the exception that two times $E_{T}\left(C=C, 2 s p^{3}\right)$ (Eq. (14.247)) is subtracted from $E_{T}\left(\mathrm{CH}_{2}\right)$ in Eq. (13.514).

$$
\begin{align*}
& V_{e}=2(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-76.00757 \mathrm{eV}  \tag{14.303}\\
& V_{p}=\frac{2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=26.60266 \mathrm{eV}  \tag{14.304}\\
& T=2(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=24.21459 \mathrm{eV}  \tag{14.305}\\
& V_{m}=2(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-12.10730 \mathrm{eV}  \tag{14.306}\\
& \left.\left.E_{T_{\text {calteres }}}\left(C H_{2}\right)=\binom{-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[( 0 . 9 1 7 7 1 ) \left(2-\frac{1}{2} \frac{a_{0}}{a}\right.\right.}{-14.63489 \mathrm{eV}-(-2.26758 \mathrm{eV})} \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]\right)=-49.66493 \mathrm{eV}
\end{align*}
$$

where $E_{T_{\text {cllykene }}}\left(\mathrm{CH}_{2}\right)$ is given by Eq. (14.270) which is reiteratively matched to Eq. (13.496) within five-significant-figure round off error.

## VIBRATION OF THE ${ }^{12} \mathrm{CH}_{2}$ GROUPS

The vibrational energy levels of $\mathrm{CH}_{2}$ in ethylene may be solved as two equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERMS OF THE ${ }^{12} \mathrm{CH}_{2}$ GROUPS

The equations of the radiation reaction force of the $\mathrm{CH}_{2}$ groups in ethylene are the same as those of the dihydrogen carbide radical with the substitution of the $\mathrm{CH}_{2}$-group parameters. Using Eq. (13.515), the angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=2.75685 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{14.308}
\end{equation*}
$$

where $b$ is given by Eq. (14.277). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 2.75685 \times 10^{16} \mathrm{rad} / \mathrm{s}=18.14605 \mathrm{eV} \tag{14.309}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each $H_{2}$-type MO, for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.309) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of each of the two bonds for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-31.63537 \mathrm{eV} \sqrt{\frac{2 e(18.14605 \mathrm{eV})}{m_{e} c^{2}}}=-0.26660 \mathrm{eV} \tag{14.310}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of $\mathrm{CH}_{2}$ due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.310) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of each $C-H$ bond. Using $\omega_{e}$ given by Eq. (13.458) for $\bar{E}_{\text {Kvib }}$ of the transition state having two independent bonds, $\bar{E}_{\text {ethylene osc }}^{\prime}\left({ }^{12} \mathrm{CH}_{2}\right)$ per bond is:

$$
\begin{align*}
& \bar{E}_{\text {ethylene osc }}^{\prime}\left({ }^{12} \mathrm{CH}_{2}\right)=\bar{E}_{D}+\bar{E}_{\text {Kvib }}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{14.311}\\
& \bar{E}_{\text {eltylene osc }}^{\prime}\left({ }^{12} \mathrm{CH}_{2}\right)=-0.26660 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})=-0.08894 \mathrm{eV} \tag{14.312}
\end{align*}
$$

Given that the vibration and reentrant oscillation is for two $\mathrm{C}-\mathrm{H}$ bonds, $\overline{\mathrm{E}}_{\text {ethylene osc }}\left({ }^{12} \mathrm{CH}_{2}\right)$, is:

$$
\begin{equation*}
\bar{E}_{\text {ethylene osc }}\left({ }^{12} \mathrm{CH}_{2}\right)=2\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)=2\left(-0.26660 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})\right)=-0.17788 \mathrm{eV} \tag{14.313}
\end{equation*}
$$

## TOTAL AND DIFFERENCE ENERGIES OF THE ${ }^{12} \mathrm{CH}_{2}$ GROUPS

$E_{\text {ethyleneT + osc }}\left({ }^{12} \mathrm{CH}_{2}\right)$, the total energy of each ${ }^{12} \mathrm{CH}_{2}$ group including the Doppler term, is given by the sum of $E_{T_{\text {elthlene }}}\left(\mathrm{CH}_{2}\right)$ (Eq. (14.307)) and $\bar{E}_{\text {ethylene osc }}\left({ }^{12} \mathrm{CH}_{2}\right)$ given by Eq. (14.313):

$$
\begin{align*}
E_{\text {ethyleneT } T \text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right) & =\binom{V_{e}+T+V_{m}+V_{p}+E\left(C, 2 s p^{3}\right)}{-2 E_{T}\left(\mathrm{C}=\mathrm{C}, 2 s p^{3}\right)+\bar{E}_{\text {ethylene osc }}\left({ }^{12} \mathrm{CH}_{2}\right)}  \tag{14.314}\\
& =E_{T_{\text {eltylene }}}\left(\mathrm{CH}_{2}\right)+\bar{E}_{\text {ethylene osc }}\left({ }^{12} \mathrm{CH}_{2}\right)
\end{align*}
$$

$$
\begin{align*}
E_{\text {ethyleneT +osc }}\left({ }^{12} \mathrm{CH}_{2}\right) & =\left\{\begin{array}{l}
\binom{\frac{-2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]}{-14.63489 \mathrm{eV}-(-2.26759 \mathrm{eV})} \\
\left.-2(31.63536831 \mathrm{eV}) \sqrt{\frac{\sqrt{\frac{3}{4} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}}{m_{e}}}-\frac{1}{m_{e} c^{2}} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{array}\right)  \tag{14.315}\\
& =-49.66493 \mathrm{eV}-2\left(0.26660 \mathrm{eV}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{align*}
$$

From Eqs. (14.313-14.315), the total energy of each ${ }^{12} \mathrm{CH}_{2}$ is:

$$
\begin{align*}
E_{\text {ethylene } T+\text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right) & =-49.66493 \mathrm{eV}+\bar{E}_{\text {ethylene osc }}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =-49.66493 \mathrm{eV}-2\left(0.26660 \mathrm{eV}-\frac{1}{2}(0.35532 \mathrm{eV})\right)  \tag{14.316}\\
& =-49.84282 \mathrm{eV}
\end{align*}
$$

where $\omega_{e}$ given by Eq. (13.458) was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The total energy for each dihydrogen carbide radical given by Eq. (13.523) is:

$$
\begin{align*}
E_{\text {radicalT }+ \text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right) & =-49.66493 \mathrm{eV}+\bar{E}_{\text {radicalosc }}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =-49.66493 \mathrm{eV}-2\left(0.25493 \mathrm{eV}-\frac{1}{2}(0.35532 \mathrm{eV})\right)  \tag{14.317}\\
& =-49.81948 \mathrm{eV}
\end{align*}
$$

The difference in energy between the $\mathrm{CH}_{2}$ groups and the dihydrogen carbide radical $\Delta E_{T+\text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right)$ is given by two times the difference between Eqs. (14.316) and (14.317):

$$
\begin{align*}
\Delta E_{T+\text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right) & =2\left(E_{\text {ethylene } T+\text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right)-E_{\text {radicalT }+ \text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right)\right) \\
& =2(-49.84282 \mathrm{eV}-(-49.81948 \mathrm{eV}))  \tag{14.318}\\
& =-0.04667 \mathrm{eV}
\end{align*}
$$

## SUM OF THE ENERGIES OF THE $C=C \quad \sigma$ MO AND THE HOS OF ETHYLENE

The energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ of the $C=C$-bond MO are the same as those of the $C H$ MO except that each term is multiplied by two corresponding to the double bond and the energy term corresponding to the $C_{\text {ethylene }} 2 s p^{3}$ HOs in the equation for $E_{T}$ is zero. The energies of each $C=C$-bond MO are given by the substitution of the semiprincipal axes (Eqs. (14.254-14.255) and (14.258)) into two times the energy equations of the $C H$ MO (Eqs. (13.449-13.453)), with the exception that zero replaces $E\left(C, 2 s p^{3}\right)$ in Eq. (13.453).

$$
\begin{align*}
& V_{e}=2(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-102.08992 \mathrm{eV}  \tag{14.319}\\
& V_{p}=2 \frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=21.48386 \mathrm{eV}  \tag{14.320}\\
& T=2(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=34.67062 \mathrm{eV}  \tag{14.321}\\
& V_{m}=2(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-17.33531 \mathrm{eV}  \tag{14.322}\\
& E_{T}(C=C, \sigma)=-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]=-63.27075 \mathrm{eV} \tag{14.323}
\end{align*}
$$

where $E_{T}(C=C, \sigma)$ is the total energy of the $C=C \quad \sigma$ MO given by Eq. (14.251) which is reiteratively matched to two times Eq. (13.75) within five-significant-figure round off error.

The total energy of the $C=C$-bond MO, $E_{T}(C=C)$, is given by the sum of two times $E_{T}\left(C=C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell due to the decrease in radius with the formation of the $C=C$-bond MO (Eq. (14.247)), and $E_{T}(C=C, \sigma)$, the $\sigma$ MO contribution given by Eq. (14.252).

$$
\begin{align*}
E_{T}(C=C) & =2 E_{T}\left(C=C, 2 s p^{3}\right)+E_{T}(C=C, \sigma) \\
& =\left(\left(-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]\right)\right)  \tag{14.324}\\
& =2(-1.13380 \mathrm{eV})+(-63.27074 \mathrm{eV}) \\
& =-65.53833 \mathrm{eV}
\end{align*}
$$

## VIBRATION OF ETHYLENE

The vibrational energy levels of $\mathrm{CH}_{2} \mathrm{CH}_{2}$ may be solved as two sets of two equivalent coupled harmonic oscillators with a bridging harmonic oscillator by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERMS OF THE $C=C$-BOND MO OF ETHYLENE

The equations of the radiation reaction force of the $C=C$-bond MO are given by Eq. (13.142), except the force-constant factor is $(0.93172) 0.5$ based on the force constant $k^{\prime}$ of Eq. (14.248), and the $C=C$-bond MO parameters are used. The angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{0.91771 \frac{(0.5) e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=4.30680 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{14.325}
\end{equation*}
$$

where $b$ is given by Eq. (14.258). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 4.30680 \times 10^{16} \mathrm{rad} / \mathrm{s}=28.34813 \mathrm{eV} \tag{14.326}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}(C=C) / 2$ (Eq. (14.324)) for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.326) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of each of the two bonds for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-32.76916 \mathrm{eV} \sqrt{\frac{2 e(28.34813 \mathrm{eV})}{m_{e} c^{2}}}=-0.34517 \mathrm{eV} \tag{14.327}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $C=C$-bond MO due to the reentrant orbit of the bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.327) and $\bar{E}_{K v i b}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of the $C=C$ bond. Using the experimental $C=C E_{v i b}\left(v_{3}\right)$ of $1443.5 \mathrm{~cm}^{-1}(0.17897 \mathrm{eV})$ [12] for $\bar{E}_{K v i b}$ of the transition state having two bonds, $\bar{E}_{\text {osc }}^{\prime}(C=C, \sigma)$ per bond is:

$$
\begin{align*}
& \bar{E}_{o s c}^{\prime}(C=C, \sigma)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{14.328}\\
& \bar{E}_{o s c}^{\prime}(C=C, \sigma)=-0.34517 \mathrm{eV}+\frac{1}{2}(0.17897 \mathrm{eV})=-0.25568 \mathrm{eV} \tag{14.329}
\end{align*}
$$

Given that the vibration and reentrant oscillation is for two $C-C$ bonds of the $C=C$ double bond, $\bar{E}_{\text {ethylene osc }}(C=C, \sigma)$, is:

$$
\begin{equation*}
\bar{E}_{\text {ethylene osc }}(C=C, \sigma)=2\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)=2\left(-0.34517 \mathrm{eV}+\frac{1}{2}(0.17897 \mathrm{eV})\right)=-0.51136 \mathrm{eV} \tag{14.330}
\end{equation*}
$$

## TOTAL ENERGIES OF THE $C=C$-BOND MO OF ETHYLENE

$E_{T+o s c}(C=C)$, the total energy of the $C=C$-bond MO including the Doppler term, is given by the sum of $E_{T}(C=C)$ (Eq. (14.324)) and $\bar{E}_{\text {ethylene osc }}(C=C, \sigma)$ given by Eq. (14.330).

$$
\begin{align*}
E_{T+\text { osc }}(C=C) & =V_{e}+T+V_{m}+V_{p}+2 E_{T}\left(C=C, 2 s p^{3}\right)+\bar{E}_{\text {ethylene osc }}(C=C, \sigma) \\
& =E_{T}(C=C, \sigma)+2 E_{T}\left(C=C, 2 s p^{3}\right)+\bar{E}_{\text {ethylene osc }}(C=C, \sigma)  \tag{14.331}\\
& =E_{T}(C=C)+\bar{E}_{\text {ethylene osc }}(C=C, \sigma) \\
E_{T+\text { osc }}(C=C) & =\left\{\begin{array}{l}
\left(\frac{-2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]+2 E_{T}\left(C=C, 2 s p^{3}\right)\right) \\
\left(1+(2)\left(\frac{1}{2}\right) \sqrt{\left.\frac{2 \hbar \sqrt{\frac{(0.91771) \frac{1}{2} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}}{m_{e}}\right)+2\left(\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)}\right\} \\
\end{array}\right)  \tag{14.332}\\
& -65.53833 \mathrm{eV}-2\left(0.34517 \mathrm{eV}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{align*}
$$

From Eqs. (14.330-14.332), the total energy of the $C=C$-bond MO is:

$$
\begin{align*}
E_{T+\text { osc }}(C=C) & =-63.27074 \mathrm{eV}+2 E_{T}\left(C=C, 2 s p^{3}\right)+\bar{E}_{\text {ethylene osc }}(C=C, \sigma) \\
& =-63.27074 \mathrm{eV}+2(-1.13380 \mathrm{eV})-2\left(0.34517 \mathrm{eV}-\frac{1}{2}(0.17897 \mathrm{eV})\right)  \tag{14.333}\\
& =-66.04969 \mathrm{eV}
\end{align*}
$$

where the experimental $E_{v i b}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.

## BOND ENERGY OF THE $C=C$ BOND OF ETHYLENE

The dissociation energy of the $\mathrm{C}=\mathrm{C}$ bond of $\mathrm{CH}_{2} \mathrm{CH}_{2}, \mathrm{E}_{\mathrm{D}}\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{CH}_{2}\right)$, is given by four times $E\left(\mathrm{C}, 2 \mathrm{sp}{ }^{3}\right)$ (Eq. (14.146)), the initial energy of each $\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO}$ of each $\mathrm{CH}_{2}$ radical that forms the double $\mathrm{C}=\mathrm{C}$ bond, minus the sum of $\Delta E_{T+\text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right)$ (Eq. (14.318)), the energy change going from the dihydrogen carbide radicals to the $\mathrm{CH}_{2}$ groups of ethylene, and $E_{T+\text { osc }}(C=C)$ (Eq. (14.333)). Thus, the dissociation energy of the $\mathrm{C}=\mathrm{C}$ bond of $\mathrm{CH}_{2} \mathrm{CH}_{2}$, is:

$$
\begin{align*}
E_{D}\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{CH}_{2}\right) & =4\left(E\left(\mathrm{C}, 2 \mathrm{sp}{ }^{3}\right)\right)-\left(\Delta E_{T+\text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right)+E_{T+\text { osc }}(\mathrm{C}=\mathrm{C})\right) \\
& =4(-14.63489 \mathrm{eV})-(-0.04667 \mathrm{eV}-66.04969 \mathrm{eV})  \tag{14.334}\\
& =4(-14.63489 \mathrm{eV})-(-66.09636 \mathrm{eV}) \\
& =7.55681 \mathrm{eV}
\end{align*}
$$

The experimental dissociation energy of the $\mathrm{C}=\mathrm{C}$ bond of $\mathrm{CH}_{2} \mathrm{CH}_{2}$ is [7]:

$$
\begin{equation*}
E_{D}\left(\mathrm{H}_{2} \mathrm{C}-\mathrm{CH}_{2}\right)=7.5969 \mathrm{eV} \tag{14.335}
\end{equation*}
$$

The results of the determination of bond parameters of $\mathrm{CH}_{2} \mathrm{CH}_{2}$ are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## ACETYLENE MOLECULE ( CHCH )

The acetylene molecule CHCH is formed by the reaction of two hydrogen carbide radicals:
$\mathrm{CH}+\mathrm{CH} \rightarrow \mathrm{CHCH}$
CHCH can be solved using the same principles as those used to solve the methane series $\mathrm{CH}_{n=1,2,3,4}$ as well as ethane, wherein the $2 s$ and $2 p$ shells of each $C$ hybridize to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. First, two sets of one $H$ atomic orbital (AO) combine with two sets of one carbon $2 s p^{3}$ HO to form two hydrogen carbide groups comprising a linear combination of two diatomic $\mathrm{H}_{2}$-type MOs developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section. Then, the two CH groups bond by forming a $\mathrm{H}_{2}$-type MO between the remaining three $\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HOs}$ on each carbon atom.

## FORCE BALANCE OF THE $C \equiv C$-BOND MO OF ACETYLENE

CHCH comprises a chemical bond between two CH radicals wherein each radical comprises a chemical bond between a carbon and a hydrogen atom. The solution of the parameters of $C H$ is given in the Hydrogen Carbide ( CH ) section. The $\mathrm{C}-\mathrm{H}$ bond of CH having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of $75 \% H_{2}$-type ellipsoidal MO and $25 \% C 2 s p^{3} \mathrm{HO}$. The proton of the $H$ atom and the nucleus of the $C$ atom are along each internuclear axis and serve as the foci. As in the case of $H_{2}$, the $C-H$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $C 2 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C 2 s p^{3}$ shell since it is energetically unfavorable. Thus, the MO surface comprises a prolate spheroid at the $H$ proton that is continuous with the $C 2 s p^{3}$ shell at the $C$ atom whose nucleus serves as the other focus. The electron configuration and the energy, $E\left(C, 2 s p^{3}\right)$, of the $C 2 s p^{3}$ shell is given by Eqs. (13.422) and (13.428), respectively. The central paramagnetic force due to spin of the $C-H$ bond is provided by the spin-pairing force of the $C H$ MO that has the symmetry of an $s$ orbital that superimposes with the $C 2 s p^{3}$ orbitals such that the corresponding angular momenta are unchanged.

Two CH radicals bond to form CHCH by forming a MO between the two pairs of three remaining $C 2 s p^{3}-\mathrm{HO}$ electrons of the two carbon atoms. However, in this case, the sharing of electrons between two $C 2 s p^{3}$ HOs to form a MO comprising six spin-paired electrons permits each $C 2 s p^{3} \mathrm{HO}$ to decrease in radius and energy.

As in the case of the $C-H$ bonds, the $C \equiv C$-bond MO is a prolate-spheroidal-MO surface that cannot extend into $C 2 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C 2 s p^{3}$ shell of each atom. Thus, the MO surface comprises a partial prolate spheroid in between the carbon nuclei and is continuous with the $C 2 s p^{3}$ shell at each $C$ atom. The energy of the $H_{2}$ type ellipsoidal MO is matched to that of the $C 2 s p^{3}$ shell. As in the case of previous examples of energy-matched MOs such as those of $\mathrm{OH}, \mathrm{NH}, \mathrm{CH}$, the $\mathrm{C}=\mathrm{O}$-bond MO of $\mathrm{CO}_{2}$, the $\mathrm{C}-\mathrm{C}$-bond MO of $\mathrm{CH}_{3} \mathrm{CH}_{3}$, and the $\mathrm{C}=\mathrm{C}$-bond MO of $\mathrm{CH}_{2} \mathrm{CH}_{2}$, the $\mathrm{C} \equiv \mathrm{C}$-bond MO of acetylene must comprise $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO in order to match potential, kinetic, and orbital energy relationships. Thus, the $C \equiv C$-bond MO must comprise a linear combination of three MOs wherein each comprises two $C 2 s p^{3} \mathrm{HOs}$ and $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO divided between the $C 2 s p^{3} \mathrm{HOs}$ :

$$
\begin{equation*}
3\left(2 \mathrm{C} 2 s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO}\right) \rightarrow \mathrm{C} \equiv \mathrm{C} \text { - bond } \mathrm{MO} \tag{14.337}
\end{equation*}
$$

The linear combination of each $H_{2}$-type ellipsoidal MO with each $C 2 s p^{3} \mathrm{HO}$ further comprises an excess $25 \%$ charge-density contribution from each $C 2 s p^{3} \mathrm{HO}$ to the $C \equiv C$-bond MO to achieve an energy minimum. The force balance of the $C \equiv C$ bond MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.337) and the energy matching condition between the $C 2 s p^{3}-\mathrm{HO}$ components of the MO.

Similarly, the energies of each $C H$ MO involve each $C 2 s p^{3}$ and each $H 1 s$ electron with the formation of each $C-H$ bond. The sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $C 2 s p^{3}$ shell. This energy is determined by the considering the effect of the donation of $25 \%$ electron density from the three pairs of $C 2 s p^{3} \mathrm{HOs}$ to the $C \equiv C$-bond MO with the formation of the $C_{\text {acetylene }} 2 s p^{3}$ HOs each having a smaller radius. The $2 s p^{3}$ hybridized orbital arrangement is given by Eq. (14.140). The sum $E_{T}\left(C, 2 s p^{3}\right)$ of calculated energies of $C, C^{+}, C^{2+}$, and $C^{3+}$ is given by Eq. (14.141). The radius $r_{2 s p^{3}}$ of the $C 2 s p^{3}$ shell is given by Eq. (14.142). The Coulombic energy $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ and the energy $E\left(C, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell are given by Eqs. (14.143) and (14.146), respectively.

Next, consider the formation of the $C \equiv C$-bond MO of acetylene from two $C H$ radicals, each having a $C 2 s p^{3}$ electron with an energy given by Eq. (14.146). The total energy of the state is given by the sum over the four electrons. The sum $E_{T}\left(C_{\text {acetylene }}, 2 s p^{3}\right)$ of calculated energies of $C 2 s p^{3}, C^{+}, C^{2+}$, and $C^{3+}$ from Eqs. (10.123), (10.113-10.114), (10.68), and (10.48), respectively, is

$$
\begin{align*}
E_{T}\left(C_{\text {acetylene }}, 2 s p^{3}\right) & =-\left(64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+E\left(C, 2 s p^{3}\right)\right) \\
& =-(64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+14.63489 \mathrm{eV})  \tag{14.338}\\
& =-151.61569 \mathrm{eV}
\end{align*}
$$

where $E\left(C, 2 s p^{3}\right)$ (Eq. (14.146)) is the sum of the energy of $C,-11.27671 \mathrm{eV}$, and the hybridization energy. The orbital-angular-momentum interactions also cancel such that the energy of the $E_{T}\left(C_{\text {acetylene }}, 2 s p^{3}\right)$ is purely Coulombic.

The sharing of electrons between three pairs of $C 2 s p^{3}$ HOs to form a $C \equiv C$-bond MO permits each participating hybridized orbital to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each participating $C 2 s p^{3} \mathrm{HO}$ donates an excess of $25 \%$ of its electron density to the $C \equiv C$-bond MO to form an energy minimum. By considering this electron redistribution in the acetylene molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{\text {acetylene2sp }}$ of the $C 2 s p^{3}$ shell of acetylene may be calculated from the Coulombic energy using Eq. (10.102).

$$
\begin{equation*}
r_{\text {acetylene } 2 s p^{3}}=\left(\sum_{n=2}^{5}(Z-n)-0.75\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 151.61569 \mathrm{eV})}=\frac{9.25 e^{2}}{8 \pi \varepsilon_{0}(e 151.61569 \mathrm{eV})}=0.83008 a_{0} \tag{14.339}
\end{equation*}
$$

where $Z=6$ for carbon. Using Eqs. (10.102) and (14.339), the Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {acetylene }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(C_{\text {acetylene }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {acetylene } 2 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.83008 a_{0}}=-16.39089 \mathrm{eV} \tag{14.340}
\end{equation*}
$$

During hybridization, the spin-paired $2 s$ electrons are promoted to the $C 2 s p^{3}$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (13.152). Using Eqs. (14.145) and (14.340), the energy $E\left(C_{\text {acetylene }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is

$$
\begin{equation*}
E\left(C_{\text {acetylene }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {acetylene2sp3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-16.39089 \mathrm{eV}+0.19086 \mathrm{eV}=-16.20002 \mathrm{eV} \tag{14.341}
\end{equation*}
$$

Thus, $E_{T}\left(C \equiv C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell with the formation of the $C \equiv C$-bond MO is given by the difference between Eq. (14.146) and Eq. (14.341):

$$
\begin{equation*}
E_{T}\left(C \equiv C, 2 s p^{3}\right)=E\left(C_{\text {acetylene }}, 2 s p^{3}\right)-E\left(C, 2 s p^{3}\right)=-16.20002 \mathrm{eV}-(-14.63489 \mathrm{eV})=-1.56513 \mathrm{eV} \tag{14.342}
\end{equation*}
$$

As in the case of $\mathrm{Cl}_{2}$, each $\mathrm{H}_{2}$-type ellipsoidal MO comprises $75 \%$ of the $C \equiv C$-bond MO shared between two $C 2 s p^{3}$ HOs corresponding to the electron charge density in Eq. (11.65) of $\frac{-0.75 e}{2}$. But, the additional $25 \%$ charge-density contribution to each bond of the $C \equiv C$-bond MO causes the electron charge density in Eq. (11.65) to be $\frac{-e}{2}=-0.5 e$. The corresponding force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ in terms of the central force of the foci (Eq. (11.65)) is given by Eq. (14.152). The distance from the origin to each focus $c^{\prime}$ is given by Eq. (14.153). The internuclear distance is given by Eq. (14.154). The length of the semiminor axis of the prolate spheroidal $C \equiv C$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of the $C \equiv C$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the $C \equiv C$-bond MO are solved.

The general equations for the energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ of the $C \equiv C$-bond MO are the same as those of the $C H$ MO except that energy of the $C_{\text {acetylene }} 2 s p^{3} \mathrm{HO}$ is used and the triple-bond nature is considered. In the case of a single bond, the prolate spheroidal $H_{2}$-type MO transitions to the $C_{\text {acetylene }} 2 s p^{3} \mathrm{HO}$ of each carbon, and the energy of the $C_{\text {acetylene }} 2 s p^{3}$ shell must remain constant and equal to the $E\left(C_{\text {acetylene }}, 2 s p^{3}\right)$ given by Eq. (14.391). Thus, the energy $E\left(C_{\text {acetylene }}, 2 s p^{3}\right)$ in Eq. (14.391) adds to that of the energies of the corresponding $H_{2}$-type ellipsoidal MO. The second and third bonds of the triple $C \equiv C$-bond MO also transition to each $C_{\text {acetylene }} 2 s p^{3} \mathrm{HO}$ of each $C$. The energy of a second and a third
$H_{2}$-type ellipsoidal MO adds to the first energy component, and the three bonds achieve an energy minimum as a linear combination of the three $\mathrm{H}_{2}$-type ellipsoidal MOs each having the carbon nuclei as the foci. Each $\mathrm{C}-\mathrm{C}$-bond MO comprises the same $C_{\text {acetylene }} 2 s p^{3} \mathrm{HO}$ shells of constant energy given by Eq. (14.391). As in the case of the water, $\mathrm{NH}_{2}$, ammonia, and ethylene molecules given by Eqs. (13.180), (13.320), (13.372), and (14.251), respectively, the energy of the redundant shell is subtracted from the total energy of the linear combination of the $\sigma$ MO. Thus, the total energy $E_{T}(C \equiv C, \sigma)$ of the $\sigma$ component of the $C \equiv C$-bond MO is given by the sum of the energies of the three bonds each comprising the linear combination of the $C_{\text {acetylene }} 2 s p^{3} \mathrm{HO}$ and the $H_{2}$-type ellipsoidal MO as given by Eq. (14.337) wherein the $E_{T}$ terms add positively and the $E\left(C_{\text {acetylene }}, 2 s p^{3}\right)$ term is positive due to the sum over a negative and two positive terms. Using Eqs. (13.431) and (14.341), $E_{T}(C \equiv C, \sigma)$ is given by:

$$
\begin{align*}
E_{T}(C \equiv C, \sigma) & =E_{T}+E\left(C_{\text {acetylene }}, 2 s p^{3}\right)-E\left(C_{\text {acetylene }}, 2 s p^{3}\right)-E\left(C_{\text {acetylene }}, 2 s p^{3}\right) \\
& =-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-E\left(C_{\text {acetylene }}, 2 s p^{3}\right)  \tag{14.343}\\
& =-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]+16.20002 \mathrm{eV}
\end{align*}
$$

The total energy term of the triple $C \equiv C$-bond MO is given by the sum of the three $H_{2}$-type ellipsoidal MOs given by Eq. (11.212). To match this boundary condition, $E_{T}(C \equiv C, \sigma)$ given by Eq. (14.343) is set equal to three times Eq. (13.75):

$$
\begin{equation*}
E_{T}(C \equiv C, \sigma)=-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]+16.20002 \mathrm{eV}=-94.90610 \mathrm{eV} \tag{14.344}
\end{equation*}
$$

From the energy relationship given by Eq. (14.344) and the relationship between the axes given by Eqs. (14.153-14.154) and (13.62-13.63), the dimensions of the $C \equiv C$-bond MO can be solved.

Substitution of Eq. (14.153) into Eq. (14.344) gives:

$$
\begin{equation*}
\frac{3 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a a_{0}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{a a_{0}}}{a-\sqrt{a a_{0}}}-1\right]=e 111.10613 \tag{14.345}
\end{equation*}
$$

The most convenient way to solve Eq. (14.345) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is

$$
\begin{equation*}
a=1.28714 a_{0}=6.81122 \times 10^{-11} \mathrm{~m} \tag{14.346}
\end{equation*}
$$

Substitution of Eq. (14.346) into Eq. (14.153) gives:

$$
\begin{equation*}
c^{\prime}=1.13452 a_{0}=6.00362 \times 10^{-11} \mathrm{~m} \tag{14.347}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.347) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.26904 a_{0}=1.20072 \times 10^{-10} \mathrm{~m} \tag{14.348}
\end{equation*}
$$

The experimental bond distance is [3]:

$$
\begin{equation*}
2 c^{\prime}=1.203 \times 10^{-10} \mathrm{~m} \tag{14.349}
\end{equation*}
$$

Substitution of Eqs. (14.346-14.347) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=0.60793 a_{0}=3.21704 \times 10^{-11} \mathrm{~m} \tag{14.350}
\end{equation*}
$$

Substitution of Eqs. (14.346-14.347) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.88143 \tag{14.351}
\end{equation*}
$$

The nucleus of the $C$ atoms comprise the foci of the $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C_{\text {acetylene }} 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{\text {acetylene2sp }}=0.83008 a_{0}$ is the radius of the $C_{\text {acetylene }} 2 s p^{3}$ shell. Substitution of Eqs. (14.346-14.347) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=137.91^{\circ} \tag{14.352}
\end{equation*}
$$

Then, the angle $\theta_{C=C_{\text {acetylene }} 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C \equiv C_{\text {acetylene }} 2 s p^{3} H O}=180^{\circ}-137.91^{\circ}=42.09^{\circ} \tag{14.353}
\end{equation*}
$$

as shown in Figure 14.11.

Figure 14.11. The cross section of the $C \equiv C$-bond $\mathrm{MO}(\sigma \mathrm{MO})$ and one $C-H$-bond MO of acetylene showing the axes, angles, and point of intersection of each $H_{2}$-type ellipsoidal MO with the corresponding $C_{\text {acetylene }} 2 s p^{3}$ HO. The continuation of each $H_{2}$-type-ellipsoidal-MO basis element of the $C \equiv C$ bond and the $C-H$-bond beyond the intersection point with each $C_{\text {acetylene }} 2 s p^{3}$ shell and $\sigma$ MO is shown as dashed since each only serves to solve the energy match with the $C_{\text {acetylene }} 2 s p^{3}$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of each intersection point. The actual charge density is shown by the solid lines. Legend: $a$ : semimajor axis, $b:$ semiminor axis, $c^{\prime}$ : internuclear distance, $\quad d_{1}: d_{C=C_{\text {acetylene }}, H_{2} M O}, \quad \theta_{1}: \theta_{C=C_{\text {acetylyene }} 2 s p^{3} H O}, \quad d_{2}: d_{C=C_{\text {acetylene }} 2 s p^{3} H O}, \quad R: r_{\text {acetylene } 2 s p^{3}}, \quad \theta_{2}: \theta_{C-H_{\text {acetylene }} 2 s p^{3} H O}$, $d_{3}: d_{C-H_{\text {acetylene }}, H_{2} M O}$, and $d_{4}: d_{C-H_{\text {acetylene }} 2 s p^{3} H O}$.

Consider the right-hand intersection point. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$ coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{C \equiv C_{\text {acetylene }}, H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{\text {acetylene } 2 s p^{3}} \sin \theta_{C \equiv C_{\text {acetylene }} 2 s p^{3} H O}=0.83008 a_{0} \sin \theta_{C \equiv C_{\text {acetylene } 2 s p^{3} H O}}=b \sin \theta_{C \equiv C_{\text {acetylene }}, H_{2} M O} \tag{14.354}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{C \equiv C_{\text {aceitylene }}, H_{2} M O}=\sin ^{-1} \frac{0.83008 a_{0} \sin \theta_{C \equiv C_{\text {acetylene }} 2 s p^{3} H O}}{b}=\sin ^{-1} \frac{0.83008 a_{0} \sin 42.09^{\circ}}{b} \tag{14.355}
\end{equation*}
$$

with the use of Eq. (14.353). Substitution of Eq. (14.350) into Eq. (14.355) gives:

$$
\begin{equation*}
\theta_{C \equiv C_{\text {acetylyene },} H_{2} M O}=66.24^{\circ} \tag{14.356}
\end{equation*}
$$

Then, the distance $d_{C=C_{\text {acetylene }}, H_{2} M O}$ along the internuclear axis from the origin of $H_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C \equiv C_{\text {acetylene }}, H_{2} M O}=a \cos \theta_{C \equiv C_{\text {acetylene } e}, H_{2} M O} \tag{14.357}
\end{equation*}
$$

Substitution of Eqs. (14.346) and (14.356) into Eq. (14.357) gives:

$$
\begin{equation*}
d_{C \equiv C_{\text {acetylene }}, H_{2} M O}=0.51853 a_{0}=2.74396 \times 10^{-11} \mathrm{~m} \tag{14.358}
\end{equation*}
$$

The distance $d_{C \equiv C_{\text {acetylene }} 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C \equiv C_{\text {acetylene }} 2 s p^{3} H O}=c^{\prime}-d_{C \equiv C_{\text {acetylene }}, H_{2} M O} \tag{14.359}
\end{equation*}
$$

Substitution of Eqs. (14.347) and (14.358) into Eq. (14.359) gives:

$$
\begin{equation*}
d_{C \equiv C_{\text {acetylene }} 2 s p^{3} H O}=0.61599 a_{0}=3.25966 \times 10^{-11} \mathrm{~m} \tag{14.360}
\end{equation*}
$$

## FORCE BALANCE OF THE $C H$ MOS OF ACETYLENE

The $C-H$ bond of each of the two equivalent $C H$ MOs must comprise $75 \%$ of a $H_{2}$-type ellipsoidal MO and a $C 2 s p^{3} \mathrm{HO}$ as given by Eq. (13.429):
$1 \mathrm{C} 2 s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO} \rightarrow \mathrm{CH} \mathrm{MO}$
(14.361)

The force balance of the CH MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.429) and the energy matching condition between the hydrogen and $C 2 s p^{3} \mathrm{HO}$ components of the MO.

The force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ of the each $H_{2}$-type-ellipsoidal-MO component of the CH MO in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus $c^{\prime}$ is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $C-H-$ bond MO. From the energy equation and the relationship between the axes, the dimensions of the CH MO are solved.

Consider the formation of the triple $C \equiv C$-bond MO of acetylene from two $C H$ radicals, each having a $C 2 s p^{3}$ shell with an energy given by Eq. (14.146). The energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ are the same as those of the hydrogen carbide radical, except that two times $E_{T}\left(C \equiv C, 2 s p^{3}\right)$ is subtracted from $E_{T}(C H)$ of Eq. (13.495). The subtraction of the energy change of the $C 2 s p^{3}$ shells with the formation of the $C \equiv C$-bond MO matches the energy of the $C-H$-bond MOs to the decrease in the energy of the $C 2 s p^{3}$ HOs. Using Eqs. (13.495) and (14.342), $E_{T_{\text {acevylene }}}(\mathrm{CH})$ is given by:

$$
\begin{equation*}
E_{T_{\text {aceflelene }}}(C H)=E_{T}+E\left(C, 2 s p^{3}\right)-2 E_{T}\left(C \equiv C, 2 s p^{3}\right)=\binom{-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]}{-14.63489 \mathrm{eV}-(-3.13026 \mathrm{eV})} \tag{14.362}
\end{equation*}
$$

$E_{T_{\text {aceverene }}}(\mathrm{CH})$ given by Eq. (14.362) is set equal to the energy of the $H_{2}$-type ellipsoidal MO given by Eq. (13.75).

$$
E_{T_{\text {acevlleece }}}(C H)=\left(\begin{array}{l}
\left.-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]\right)=-31.63537 \mathrm{eV} \text {. } 14.63489 \mathrm{eV}-(-3.13026 \mathrm{eV})  \tag{14.363}\\
-14
\end{array}\right.
$$

From the energy relationship given by Eq. (14.363) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the $C H$ MO can be solved.

Substitution of Eq. (13.60) into Eq. (14.363) gives:

$$
\begin{equation*}
\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right]=e 20.13074 \tag{14.364}
\end{equation*}
$$

The most convenient way to solve Eq. (14.364) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is

$$
\begin{equation*}
a=1.48719 a_{0}=7.86987 \times 10^{-11} \mathrm{~m} \tag{14.365}
\end{equation*}
$$

Substitution of Eq. (14.365) into Eq. (14.60) gives:

$$
\begin{equation*}
c^{\prime}=0.99572 a_{0}=5.26913 \times 10^{-11} \mathrm{~m} \tag{14.366}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.366) by two is:

$$
\begin{equation*}
2 c^{\prime}=1.99144 a_{0}=1.05383 \times 10^{-10} \mathrm{~m} \tag{14.367}
\end{equation*}
$$

The experimental bond distance is [3]:

$$
\begin{equation*}
2 c^{\prime}=1.060 \times 10^{-10} \mathrm{~m} \tag{14.368}
\end{equation*}
$$

Substitution of Eqs. (14.365-14.366) into Eq. (14.62) gives:

$$
\begin{equation*}
b=c=1.10466 a_{0}=5.84561 \times 10^{-11} \mathrm{~m} \tag{14.369}
\end{equation*}
$$

Substitution of Eqs. (14.365-14.366) into Eq. (14.63) gives:

$$
\begin{equation*}
e=0.66953 \tag{14.370}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $C$ atom comprise the foci of each $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C_{\text {acetylene }} 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{\text {acetylene2sp }}=0.83008 a_{0}$ is the radius of the $C_{\text {acetylene }} 2 s p^{3}$ shell. Substitution of Eqs. (14.365-14.366) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=90.99^{\circ} \tag{14.371}
\end{equation*}
$$

Then, the angle $\theta_{C-H_{\text {acetylene }} 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is

$$
\begin{equation*}
\theta_{C-H_{\text {acetylene }} 2 s p^{3} H O}=180^{\circ}-90.99^{\circ}=89.01^{\circ} \tag{14.372}
\end{equation*}
$$

as shown in Figure 14.11. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{C-H_{\text {acetylene }}, H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{\text {acetylene2sp }^{3}} \sin \theta_{C-H_{\text {acetylene }} 2 s p^{3} H O}=0.83008 a_{0} \sin \theta_{C-H_{\text {acetylene }} 2 s p^{3} H O}=b \sin \theta_{C-H_{\text {acetylene }}, H_{2} M O} \tag{14.373}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{C-H_{\text {acetylene } e}, H_{2} M O}=\sin ^{-1} \frac{0.83008 a_{0} \sin \theta_{C-H_{\text {acetylene }} 2 s p^{3} H O}}{b}=\sin ^{-1} \frac{0.83008 a_{0} \sin 89.01^{\circ}}{b} \tag{14.374}
\end{equation*}
$$

with the use of Eq. (14.372). Substitution of Eq. (14.369) into Eq. (14.374) gives:

$$
\begin{equation*}
\theta_{C-H_{\text {acetylene }}, H_{2} M O}=48.71^{\circ} \tag{14.375}
\end{equation*}
$$

Then, the distance $d_{C-H_{\text {acetylene }}, H_{2} M O}$ along the internuclear axis from the origin of $H_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by

$$
\begin{equation*}
d_{C-H_{\text {acetylene },} H_{2} M O}=a \cos \theta_{C-H_{\text {acetylene },}, H_{2} M O} \tag{14.376}
\end{equation*}
$$

Substitution of Eqs. (14.365) and (14.375) into Eq. (14.376) gives:

$$
\begin{equation*}
d_{3}: d_{C-H_{\text {acetylene }}, H_{2} M O}=0.98145 a_{0}=5.19359 \times 10^{-11} \mathrm{~m} \tag{14.377}
\end{equation*}
$$

The distance $d_{C-H_{\text {acetylene }} 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by

$$
\begin{equation*}
d_{C-H_{\text {acetylene }} 2 s p^{3} \mathrm{HO}}=c^{\prime}-d_{C-H_{\text {aceitlene }}, H_{2} M O} \tag{14.378}
\end{equation*}
$$

Substitution of Eqs. (14.366) and (14.377) into Eq. (14.378) gives:

$$
\begin{equation*}
d_{4}: d_{C-H_{\text {acetylene }} 2 s p^{3} H O}=0.01427 a_{0}=7.55329 \times 10^{-13} \mathrm{~m} \tag{14.379}
\end{equation*}
$$

with the $C \equiv C$ triple bond along one axis, the minimum energy is obtained with the $C-H$-bond MO at a maximum separation. Thus, the bond angle $\theta_{C \equiv C-H}$ between the internuclear axis of the $C \equiv C$ bond and the $H$ atom of the $C H$ groups is

$$
\begin{equation*}
\theta_{C \equiv C-H}=180^{\circ} \tag{14.380}
\end{equation*}
$$

The experimental angle between the $C \equiv C-H$ bonds is [6]:

$$
\begin{equation*}
\theta_{C \equiv C-H}=180^{\circ} \tag{14.381}
\end{equation*}
$$

The CHCH MO shown in Figure 14.12 was rendered using these parameters.
The charge-density in the $C \equiv C$-bond MO is increased by a factor of 0.25 per bond with the formation of the $C_{\text {acetylene }} 2 s p^{3}$ HOs each having a smaller radius. Using the orbital composition of the $C H$ groups (Eq. (14.361)) and the $C \equiv C$ bond MO (Eq. (14.337)), the radii of $C 1 s=0.17113 a_{0}$ (Eq. (10.51)) and $C_{\text {acetylene }} 2 s p^{3}=0.83008 a_{0}$ (Eq. (14.339)) shells, and the parameters of the $C \equiv C$-bond (Eqs. (13.3-13.4), (14.346-14.348), and (14.350-14.360)), the parameters of the $C-H$-bond MOs (Eqs. (13.3-13.4), (14.365-14.367), and (14.369-14.379)), and the bond-angle parameter (Eqs. (14.380-14.381)), the charge-density of the CHCH MO comprising the linear combination of two $C-H$-bond MOs and a $C \equiv C$-bond MO bridging the two CH groups is shown in Figure 14.12. Each $\mathrm{C}-\mathrm{H}$-bond MO comprises a $H_{2}$-type ellipsoidal MO and a $C_{\text {aceetilene }} 2 s p^{3}$ HO having the dimensional diagram shown in Figure 14.11. The $C \equiv C$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {acetylene }} 2 s p^{3}$ HOs having the dimensional diagram also shown in Figure 14.11.

Figure 14.12. $C H C H$ MO comprising the linear combination of two $C-H$-bond MOs and a $C \equiv C$-bond MO. (A) Color scale, translucent view of the charge-density of the $C \equiv C$-bond MO with the $C_{\text {acetylene }} 2 s p^{3}$ HOs shown transparently. The $C \equiv C$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two sets of three $C_{\text {acetylene }} 2 s p^{3}$ HOs. For each $C-H$ and the $C \equiv C$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {acetylene }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {acetylene }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown. (B)-(D) Translucent view high-lighting the $C \equiv C$ bond MO and end-on view of the charge-density of the CHCH MO , respectively.

## ENERGIES OF THE $C H$ GROUPS

The energies of each CH group of acetylene are given by the substitution of the semiprincipal axes (Eqs. (14.365-14.366) and (14.369)) into the energy equations of hydrogen carbide (Eqs. (13.510-13.514)), with the exception that two times $E_{T}\left(C \equiv C, 2 s p^{3}\right)$ (Eq. (14.342)) is subtracted from $E_{T}(C H)$ in Eq. (13.514).

$$
\begin{align*}
& V_{e}=(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-40.62396 \mathrm{eV}  \tag{14.382}\\
& V_{p}=\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=13.66428 \mathrm{eV}  \tag{14.383}\\
& T=(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=13.65796 \mathrm{eV}  \tag{14.384}\\
& V_{m}=(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-6.82898 \mathrm{eV}  \tag{14.385}\\
& E_{T_{\text {aceveleen }}}(C H)=\left(\begin{array}{l}
\left.-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]\right)=-31.63532 \mathrm{eV} \\
-14.63489 \mathrm{eV}-(-3.13026 \mathrm{eV})
\end{array}\right. \tag{14.386}
\end{align*}
$$

where $E_{T_{\text {acectlere }}}(\mathrm{CH})$ is given by Eq. (14.362) which is reiteratively matched to Eq. (13.75) within five-significant-figure round off error.

## VIBRATION OF THE ${ }^{12} \mathrm{CH}$ GROUPS

The vibrational energy levels of CH in acetylene may be solved using the methods given in the Vibration and Rotation of CH section.

## THE DOPPLER ENERGY TERMS OF THE ${ }^{12} \mathrm{CH}$ GROUPS

The equations of the radiation reaction force of the $C H$ groups in acetylene are the same as those of the hydrogen carbide radical with the substitution of the CH -group parameters. Using Eq. (13.477), the angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=3.08370 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{14.387}
\end{equation*}
$$

where $b$ is given by Eq. (14.369). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)):

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 3.08370 \times 10^{16} \mathrm{rad} / \mathrm{s}=20.29747 \mathrm{eV} \tag{14.388}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each $H_{2}$-type MO, for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.388) for $\bar{E}_{K}$ gives the Doppler energy of the electrons for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-31.63537 \mathrm{eV} \sqrt{\frac{2 e(20.29747 \mathrm{eV})}{m_{e} c^{2}}}=-0.28197 \mathrm{eV} \tag{14.389}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of CH due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.389) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of each $C-H$ bond. Using $\omega_{e}$ given by Eq. (13.458) for $\bar{E}_{\text {Kvib }}$ of the transition state, $\bar{E}_{\text {acetylene osc }}\left({ }^{12} \mathrm{CH}\right)$ is:

$$
\begin{align*}
& \bar{E}_{\text {acetylene osc }}\left({ }^{12} \mathrm{CH}\right)=\bar{E}_{D}+\bar{E}_{\text {Kvib }}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{14.390}\\
& \bar{E}_{\text {aceetylene osc }}\left({ }^{12} \mathrm{CH}\right)=-0.28197 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})=-0.10430 \mathrm{eV} \tag{14.391}
\end{align*}
$$

## TOTAL AND DIFFERENCE ENERGIES OF THE ${ }^{12} \mathrm{CH}$ GROUPS

$E_{\text {acetylene } T+\text { osc }}\left({ }^{12} \mathrm{CH}\right)$, the total energy of each ${ }^{12} \mathrm{CH}$ group including the Doppler term, is given by the sum of $E_{T_{\text {acectlene }}}(\mathrm{CH})$ (Eq. (14.386)) and $\bar{E}_{\text {acetylene osc }}\left({ }^{12} \mathrm{CH}\right)$ given by Eq. (14.391).

$$
\begin{align*}
& E_{\text {acetyleneT }+ \text { osc }}\left({ }^{12} \mathrm{CH}\right)=\binom{V_{e}+T+V_{m}+V_{p}+E\left(C, 2 s p^{3}\right)}{-2 E_{T}\left(C \equiv C, 2 s p^{3}\right)+\bar{E}_{\text {acetylene osc }}\left({ }^{12} \mathrm{CH}\right)}  \tag{14.392}\\
& =E_{T_{\text {acetlene }}}(\mathrm{CH})+\bar{E}_{\text {acetyllene osc }}\left({ }^{12} \mathrm{CH}\right) \\
& E_{\text {acetyleneT }+ \text { osc }}\left({ }^{12} \mathrm{CH}\right)=\left\{\begin{array}{l}
\binom{\left(\frac{-e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]\right.}{-14.63489 \mathrm{eV}-(-3.13026 \mathrm{eV})} \\
-\left((31.63536831 \mathrm{eV}) \sqrt{\frac{2 \hbar \sqrt{\frac{3}{\frac{3}{4} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}} m_{e}}{m_{e} c^{2}}}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{array}\right\}  \tag{14.393}\\
& =-31.63537 \mathrm{eV}-\left(0.28197 \mathrm{eV}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{align*}
$$

From Eqs. (14.391-14.393), the total energy of each ${ }^{12} \mathrm{CH}$ is:

$$
\begin{align*}
E_{\text {acetlyeneT Tosc }}\left({ }^{12} \mathrm{CH}\right) & =-31.63537 \mathrm{eV}+\bar{E}_{\text {acetylyene osc }}\left({ }^{12} \mathrm{CH}\right) \\
& =-31.63537 \mathrm{eV}-\left(0.28197 \mathrm{eV}-\frac{1}{2}(0.35532 \mathrm{eV})\right)=-31.73967 \mathrm{eV} \tag{14.394}
\end{align*}
$$

where $\omega_{e}$ given by Eq. (13.458) was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The total energy for each hydrogen carbide radical given by Eq. (13.485) is:

$$
\begin{align*}
E_{\text {radicalT }+ \text { osc }}\left({ }^{12} \mathrm{CH}\right) & =-31.63537 \mathrm{eV}+\bar{E}_{\text {radicalosc }}\left({ }^{12} \mathrm{CH}\right) \\
& =-31.63537 \mathrm{eV}-0.24966 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})  \tag{14.395}\\
& =-31.70737 \mathrm{eV}
\end{align*}
$$

The difference in energy between the $C H$ groups and the hydrogen carbide radical $\Delta E_{T+o s c}\left({ }^{12} \mathrm{CH}\right)$ is given by two times the difference between Eqs. (14.394) and (14.395).

$$
\begin{align*}
\Delta E_{T+\text { osc }}\left({ }^{12} \mathrm{CH}\right) & =2\left(E_{\text {acetyleneT Tosc }}\left({ }^{12} \mathrm{CH}\right)-E_{\text {radicalT +osc }}\left({ }^{12} \mathrm{CH}\right)\right) \\
& =2(-31.73967 \mathrm{eV}-(-31.70737 \mathrm{eV}))  \tag{14.396}\\
& =-0.06460 \mathrm{eV}
\end{align*}
$$

## SUM OF THE ENERGIES OF THE $C \equiv C$ MO AND THE HOS OF ACETYLENE

The energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ of the $C \equiv C$-bond MO are the same as those of the $C H$ MO except that each term is multiplied by three corresponding to the triple bond and the energy term corresponding to the $C_{\text {acetylene }} 2 s p^{3}$ HOs in the equation for $E_{T}$ is positive. The energies of each $C \equiv C$-bond MO are given by the substitution of the semiprincipal axes (Eqs. (14.346-14.347) and (14.350)) into three times the energy equations of the $C H$ MO (Eqs. (13.449-13.453)), with the exception that $E\left(C, 2 s p^{3}\right)$ in Eq. (13.453) is positive and given by Eq. (14.341).

$$
\begin{align*}
& V_{e}=3(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-182.53826 \mathrm{eV}  \tag{14.397}\\
& V_{p}=3 \frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=35.97770 \mathrm{eV}  \tag{14.398}\\
& T=3(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=70.90876 \mathrm{eV}  \tag{14.399}\\
& V_{m}=3(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-35.45438 \mathrm{eV}  \tag{14.400}\\
& E_{T}(C \equiv C, \sigma)=-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]+16.20002 \mathrm{eV}=-94.90616 \mathrm{eV} \tag{14.401}
\end{align*}
$$

where $E_{T}(C \equiv C, \sigma)$ is the total energy of the $C \equiv C \quad \sigma$ MO given by Eq. (14.343) which is reiteratively matched to three times Eq. (13.75) within five-significant-figure round off error.

The total energy of the $C \equiv C$-bond $\mathrm{MO}, E_{T}(C \equiv C)$, is given by the sum of two times $E_{T}\left(C \equiv C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell due to the decrease in radius with the formation of the $C \equiv C$-bond MO (Eq. (14.342)), and $E_{T}(C \equiv C, \sigma)$, the $\sigma$ MO contribution given by Eq. (14.344).

$$
\begin{align*}
E_{T}(C \equiv C) & =2 E_{T}\left(C \equiv C, 2 s p^{3}\right)+E_{T}(C \equiv C, \sigma) \\
& =\left(\left(-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]+16.20002 \mathrm{eV}\right)\right)  \tag{14.402}\\
& =2(-1.56513 \mathrm{eV})+(-94.90610 \mathrm{eV}) \\
& =-98.03637 \mathrm{eV}
\end{align*}
$$

## VIBRATION OF ACETYLENE

The vibrational energy levels of CHCH may be solved as two equivalent coupled harmonic oscillators with a bridging harmonic oscillator by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERMS OF THE $C \equiv C$-BOND MO OF ACETYLENE

The equations of the radiation reaction force of the $C \equiv C$-bond MO are given by Eq. (14.231), except that the $C \equiv C$-bond MO parameters are used. The angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.5 e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}=2.00186 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{14.403}
\end{equation*}
$$

where $a$ is given by Eq. (14.346). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 2.00186 \times 10^{16} \mathrm{rad} / \mathrm{s}=13.17659 \mathrm{eV} \tag{14.404}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}(C \equiv C) / 3$ (Eq. (14.402)) for $E_{h \nu}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.404) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h v} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-32.67879 \mathrm{eV} \sqrt{\frac{2 e(13.17659 \mathrm{eV})}{m_{e} c^{2}}}=-0.23468 \mathrm{eV} \tag{14.405}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $C \equiv C$-bond MO due to the reentrant orbit of the bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.405) and $\bar{E}_{K v i b}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of the $C \equiv C$ bond. Using the experimental $C \equiv C E_{v i b}\left(v_{3}\right)$ of $3374 \mathrm{~cm}^{-1}(0.41833 \mathrm{eV})$ [6] for $\bar{E}_{K v i b}$ of the transition state having three bonds, $\bar{E}_{\text {osc }}^{\prime}(C \equiv C, \sigma)$ per bond is:

$$
\begin{align*}
& \bar{E}_{o s c}^{\prime}(C \equiv C, \sigma)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{14.406}\\
& \bar{E}_{o s c}^{\prime}(C \equiv C, \sigma)=-0.23468 \mathrm{eV}+\frac{1}{2}(0.41833 \mathrm{eV})=-0.02551 \mathrm{eV} \tag{14.407}
\end{align*}
$$

Given that the vibration and reentrant oscillation is for three $C-C$ bonds of the $C \equiv C$ triple bond, $\bar{E}_{\text {acetvilene osc }}(C \equiv C, \sigma)$, is:

$$
\begin{align*}
\bar{E}_{\text {acetylene osc }}(C \equiv C, \sigma) & =3\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right) \\
& =3\left(-0.23468 \mathrm{eV}+\frac{1}{2}(0.41833 \mathrm{eV})\right)  \tag{14.408}\\
& =-0.07654 \mathrm{eV}
\end{align*}
$$

## TOTAL ENERGIES OF THE $C \equiv C$-BOND MO OF ACETYLENE

$E_{T+o s c}(C \equiv C)$, the total energy of the $C \equiv C$-bond MO including the Doppler term, is given by the sum of $E_{T}(C \equiv C)$ (Eq. (14.402)) and $\bar{E}_{\text {acetylene osc }}(C \equiv C, \sigma)$ given by Eq. (14.408).

$$
\begin{align*}
& E_{T+\text { osc }}(C \equiv C)=\binom{V_{e}+T+V_{m}+V_{p}-E\left(C_{\text {acetylene }}, 2 s p^{3}\right)}{+2 E_{T}\left(C \equiv C, 2 s p^{3}\right)+\bar{E}_{\text {acetylene osc }}(C \equiv C, \sigma)} \\
& =E_{T}(C \equiv C, \sigma)+2 E_{T}\left(C \equiv C, 2 s p^{3}\right)+\bar{E}_{\text {acetylene osc }}(C \equiv C, \sigma)  \tag{14.409}\\
& =E_{T}(C \equiv C)+\bar{E}_{\text {acetylene osc }}(C \equiv C, \sigma)
\end{align*}
$$

$$
\begin{aligned}
& =-98.03637 \mathrm{eV}-3\left(0.23468 \mathrm{eV}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{aligned}
$$

From Eqs. (14.408-14.410), the total energy of the $C \equiv C$-bond MO is:

$$
\begin{aligned}
E_{T+\text { osc }}(C \equiv C) & =-94.90610 \mathrm{eV}+2 E_{T}\left(C \equiv C, 2 s p^{3}\right)+\bar{E}_{\text {acetylene osc }}(C \equiv C, \sigma) \\
& =-94.90610 \mathrm{eV}+2(-1.56513 \mathrm{eV})-3\left(0.23468 \mathrm{eV}-\frac{1}{2}(0.41833 \mathrm{eV})\right) \\
& =-98.11291 \mathrm{eV}
\end{aligned}
$$

where the experimental $E_{\text {vib }}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.

## BOND ENERGY OF THE $C \equiv C$ BOND OF ACETYLENE

As in the case of ${ }^{12} \mathrm{CH}_{2}$ and ${ }^{14} \mathrm{NH}$, the dissociation of the $C \equiv C$ bond forms three unpaired electrons per central atom wherein the magnetic moments cannot all cancel. The energy per atom $E$ (magnetic) is given by Eq. (13.524). Thus, the dissociation energy of the $C \equiv C$ bond of $C H C H, E_{D}(H C \equiv C H)$, is given by six times $E\left(C, 2 s p^{3}\right)$ (Eq. (14.146)), the initial energy of each $C 2 s p^{3} \mathrm{HO}$ of each $C H$ radical that forms the triple $C \equiv C$ bond, minus the sum of $\Delta E_{T+o s c}\left({ }^{12} C H\right)$ (Eq. (14.396)), the energy change going from the hydrogen carbide radicals to the $C H$ groups of acetylene, $E_{T+\text { osc }}(C \equiv C)$ (Eq. (14.411)), and two times $E$ (magnetic) given by Eq. (13.524). Thus, the dissociation energy of the $C \equiv C$ bond of $C H C H$, is:

$$
\begin{align*}
E_{D}(H C \equiv C H) & =6\left(E\left(C, 2 s p^{3}\right)\right)-\left(\Delta E_{T+o s c}\left({ }^{12} \mathrm{CH}\right)+E_{T+\text { osc }}(C \equiv C)+2 E(\text { magnetic })\right) \\
& =6(-14.63489 \mathrm{eV})-(-0.06460 \mathrm{eV}-98.11291 \mathrm{eV}+0.29606 \mathrm{eV})  \tag{14.412}\\
& =6(-14.63489 \mathrm{eV})-(-97.88145 \mathrm{eV})=10.07212 \mathrm{eV}
\end{align*}
$$

The experimental dissociation energy of the $\mathrm{C} \equiv \mathrm{C}$ bond of CHCH is [7]:

$$
\begin{equation*}
E_{D}(H C \equiv C H)=10.0014 \mathrm{eV} \tag{14.413}
\end{equation*}
$$

The results of the determination of bond parameters of CHCH are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## BENZENE MOLECULE ( $C_{6} H_{6}$ )

The benzene molecule $\mathrm{C}_{6} \mathrm{H}_{6}$ is formed by the reaction of three ethylene molecules:

$$
\begin{equation*}
3 \mathrm{CH}_{2} \mathrm{CH}_{2} \rightarrow \mathrm{C}_{6} \mathrm{H}_{6}+3 \mathrm{H}_{2} \tag{14.414}
\end{equation*}
$$

$C_{6} H_{6}$ can be solved using the same principles as those used to solve ethylene wherein the $2 s$ and $2 p$ shells of each $C$ hybridize to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. Each $2 s p^{3} \mathrm{HO}$ of each carbon atom initially has four unpaired electrons. Thus, the $6 H$ atomic orbitals (AOs) of benzene contribute six electrons and the six $s p^{3}$-hybridized carbon atoms contribute twenty-four electrons to form six $C-H$ bonds and six $C=C$ bonds. Each $C-H$ bond has two paired electrons with one donated from the $H \mathrm{AO}$ and the other from the $C 2 s p^{3}$ HO. Each $C=C$ bond comprises a linear combination of a factor of 0.75 of four paired electrons (three electrons) from two sets of two $C 2 s p^{3}$ HOs of the participating carbon atoms. Each $C-H$ and each $C=C$ bond comprises a linear combination of one and two diatomic $\mathrm{H}_{2}$-type MOs developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section, respectively.

## FORCE BALANCE OF THE $C=C$-BOND MO OF BENZENE

$\mathrm{C}_{6} \mathrm{H}_{6}$ can be considered a linear combination of three ethylene molecules wherein a $\mathrm{C}-\mathrm{H}$ bond of each $\mathrm{CH}_{2}$ group of $\mathrm{H}_{2} \mathrm{C}=\mathrm{CH}_{2}$ is replaced by a $\mathrm{C}=\mathrm{C}$ bond to form a six-member ring of carbon atoms. The solution of the ethylene molecule is given in the Ethylene Molecule $\left(\mathrm{CH}_{2} \mathrm{CH}_{2}\right)$ section. Before forming ethylene groups, the $2 s p^{3}$ hybridized orbital arrangement of each carbon atom is given by Eq. (14.140). The sum $E_{T}\left(C, 2 s p^{3}\right)$ of calculated energies of $C, C^{+}, C^{2+}$, and $C^{3+}$ is given by Eq. (14.141). The radius $r_{2 s p^{3}}$ of the $C 2 s p^{3}$ shell is given by Eq. (14.142). The Coulombic energy $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ and the energy $E\left(C, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell are given by Eqs. (14.143) and (14.146), respectively. Two $\mathrm{CH}_{2}$ radicals bond to form $\mathrm{CH}_{2} \mathrm{CH}_{2}$ by forming a MO between the two pairs of remaining $\mathrm{C} 2 s p^{3}$ - HO electrons of the two carbon
atoms. However, in this case, the sharing of electrons between four $C 2 s p^{3} \mathrm{HOs}$ to form a MO comprising four spin-paired electrons permits each $C 2 s p^{3} \mathrm{HO}$ to decrease in radius and energy. The $C=C$-bond MO is a prolate-spheroidal-MO surface that cannot extend into $C 2 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C 2 s p^{3}$ shell of each atom. Thus, the MO surface comprises a partial prolate spheroid in between the carbon nuclei and is continuous with the $C 2 s p^{3}$ shell at each $C$ atom. The energy of the $\mathrm{H}_{2}$-type ellipsoidal MO is matched to that of each $C 2 s p^{3}$ shell. As in the case of previous examples of energymatched MOs such as those of $\mathrm{OH}, \mathrm{NH}, \mathrm{CH}$, the $\mathrm{C}=\mathrm{O}$-bond MO of $\mathrm{CO}_{2}$, and the $\mathrm{C}-\mathrm{C}$-bond MO of $\mathrm{CH}_{3} \mathrm{CH}_{3}$, the $C=C$-bond MO of ethylene must comprise $75 \%$ of a $H_{2}$-type ellipsoidal MO in order to match potential, kinetic, and orbital energy relationships. Thus, the $C=C$-bond MO must comprise a linear combination of two MOs wherein each comprises two $C 2 s p^{3} \mathrm{HOs}$ and $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO divided between the $\mathrm{C} 2 s p^{3} \mathrm{HOs}$ :

$$
\begin{equation*}
2\left(2 \mathrm{C} 2 s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO}\right) \rightarrow \mathrm{C}=\mathrm{C}-\text { bond } \mathrm{MO} \tag{14.415}
\end{equation*}
$$

The linear combination of each $H_{2}$-type ellipsoidal MO with each $C 2 s p^{3} \mathrm{HO}$ further comprises an excess $25 \%$ charge-density contribution from each $C 2 s p^{3} \mathrm{HO}$ to the $C=C$-bond MO to achieve an energy minimum. The force balance of the $C=C$ bond MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.415) and the energy matching condition between the $C 2 s p^{3}-\mathrm{HO}$ components of the MO.

The sharing of electrons between two pairs of $C 2 s p^{3} \mathrm{HOs}$ to form a $C=C$-bond MO permits each participating hybridized orbital to decrease in radius and energy. The sum $E_{T}\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ of calculated energies of $C 2 s p^{3}, C^{+}, C^{2+}$, and $C^{3+}$ is given by Eq. (14.243). In order to further satisfy the potential, kinetic, and orbital energy relationships, each participating $C 2 s p^{3} \mathrm{HO}$ donates an excess of $25 \%$ of its electron density to the $C=C$-bond MO to form an energy minimum. By considering this electron redistribution in the ethylene molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{\text {ethylene } 2 s p^{3}}$ of the $C 2 s p^{3}$ shell of ethylene calculated from the Coulombic energy is given by Eq. (14.244). The Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is given by Eq. (14.245). The energy $E\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is given by Eq. (14.246). $E_{T}\left(C=C, 2 s p^{3}\right)$ (Eq. (14.247)), the energy change of each $C 2 s p^{3}$ shell with the formation of the $C=C$-bond MO is given by the difference between $E\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ and $E\left(C, 2 s p^{3}\right)$.

Consider the case where three sets of $C=C$-bond MOs form bonds between the two carbon atoms of each molecule to form a six-member ring such that the six resulting bonds comprise eighteen paired electrons. Each bond comprises a linear combination of two MOs wherein each comprises two $C 2 s p^{3} \mathrm{HOs}$ and $75 \%$ of a $H_{2}$-type ellipsoidal MO divided between the $C 2 s p^{3} \mathrm{HOs}$ :

$$
\begin{equation*}
\binom{3\left(2 \mathrm{C} 2 s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO}\right) \rightarrow 3\left(C^{4 e} C\right) \text {-ethylene-type-bond MO}}{\rightarrow 6\left(C^{3 e}=C\right)-\text { bond MO of benzene }} \tag{14.416}
\end{equation*}
$$

The linear combination of each $H_{2}$-type ellipsoidal MO with each $C 2 s p^{3}$ HO further comprises an excess $25 \%$ charge-density contribution per bond from each $C 2 s p^{3} \mathrm{HO}$ to the $C=C$-bond MO to achieve an energy minimum. Thus, the dimensional parameters of each bond $C=C$-bond are determined using the same equations as those used to determine the same parameters of the $C=C$-bond MO of ethylene (Eqs. (14.242-14.268)) while matching the boundary conditions of the structure of benzene. The energies of each $C=C$ bond of benzene are also determined using the same equations as those of ethylene with the parameters of benzene. The result is that the energies are essentially given as 0.75 times the energies of the $C=C$-bond MO of ethylene (Eqs. (14.251-14.253) and (14.319-14.333)).

The derivation of the dimensional parameters of benzene follows the same procedure as the determination of those of ethylene. As in the case of ethylene, each $H_{2}$-type ellipsoidal MO comprises $75 \%$ of the $C=C$-bond MO shared between two $C 2 s p^{3}$ HOs corresponding to the electron charge density in Eq. (11.65) of $\frac{-0.75 e}{2}$. But, the additional $25 \%$ charge-density contribution to each bond of the $C=C$-bond MO causes the electron charge density in Eq. (11.65) to be $\frac{-e}{2}=-0.5 e$. The corresponding force constant $k^{\prime}$ is given by Eq. (14.152). In addition, the energy matching at all six $C 2 s p^{3}$ HOs further requires that $k^{\prime}$ be corrected by a hybridization factor (Eq. (13.430)) as in the case of ethylene, expect that the constraint that the bonds connect a six-member ring of $C=C$ bonds of benzene rather two $C 2 s p^{3}$ HOs of ethylene decreases the hybridization factor of benzene compared to that of ethylene (Eq. (14.248)).

Since the energy of each $H_{2}$-type ellipsoidal MO is matched to that of all the continuously connected $C_{\text {benzene }} 2 s p^{3} \mathrm{HOs}$, the hybridization-energy-matching factor is 0.85252 . Hybridization with $25 \%$ electron donation to each $C=C$-bond gives rise to the $C_{\text {benzene }} 2 s p^{3}$ HO-shell Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {benzene }}, 2 s p^{3}\right)$ given by Eq. (14.245). The corresponding hybridization factor is given by the ratio of 15.95955 eV , the magnitude of $E_{\text {Coulomb }}\left(C_{\text {benzene }}, 2 s p^{3}\right)$ given by Eq. (14.245), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). The hybridization energy factor $C_{\text {benzeneC } 2 s p^{3} H O}$ is:

$$
\begin{equation*}
C_{\text {benzeneC2sp }{ }^{3} H O}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} r_{\text {benzene2sp }}{ }^{3}}}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} 0.85252 a_{0}}}=\frac{13.605804 \mathrm{eV}}{15.95955 \mathrm{eV}}=0.85252 \tag{14.417}
\end{equation*}
$$

Thus, the force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ in terms of the central force of the foci (Eq. (11.65)) is given by:

$$
\begin{equation*}
k^{\prime}=C_{\text {benzeneC } 2 s p^{3} H O} \frac{(0.5) 2 e^{2}}{4 \pi \varepsilon_{0}}=0.85252 \frac{(0.5) 2 e^{2}}{4 \pi \varepsilon_{0}} \tag{14.418}
\end{equation*}
$$

The distance from the origin to each focus $c^{\prime}$ is given by substitution of Eq. (14.418) into Eq. (13.60). Thus, the distance from the origin of the component of the double $C=C$-bond MO to each focus $c^{\prime}$ is given by

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{(0.85252) m_{e} e^{2} a}}=\sqrt{\frac{a a_{0}}{0.85252}} \tag{14.419}
\end{equation*}
$$

The internuclear distance from Eq. (14.419) is:

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{\frac{a a_{0}}{0.85252}} \tag{14.420}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal $C=C$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of the $C=C$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the $C=C$-bond MO are solved.

The general equations for the energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ of the $C=C$-bond MO of benzene are the same as those of the $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{MO}$ except that energy of the $C_{\text {benzene }} 2 s p^{3} \mathrm{HO}$ is used and the hybridization factor is given by Eq. (14.417). Using Eqs. (14.251) and (14.417), $E_{T}(C=C, \sigma)$ is given by:

$$
\begin{equation*}
E_{T}(C=C, \sigma)=E_{T}+E\left(C_{\text {benzene }}, 2 s p^{3}\right)-E\left(C_{\text {benzene }}, 2 s p^{3}\right)=-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.85252)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right] \tag{14.421}
\end{equation*}
$$

The total energy term of the double $C=C$-bond MO is given by the sum of the two $H_{2}$-type ellipsoidal MOs given by Eq. (11.212). To match this boundary condition, $E_{T}(C=C, \sigma)$ given by Eq. (14.421) is set equal to two times Eq. (13.75):

$$
\begin{equation*}
E_{T}(C=C, \sigma)=-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.85252)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]=-63.27074 \mathrm{eV} \tag{14.422}
\end{equation*}
$$

From the energy relationship given by Eq. (14.422) and the relationship between the axes given by Eqs. (14.419-14.420) and (13.62-13.63), the dimensions of the $C=C$-bond MO can be solved.

Substitution of Eq. (14.419) into Eq. (14.422) gives:

$$
\begin{equation*}
\frac{2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{0.85252}}}\left[(0.85252)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{0.85252}}}{a-\sqrt{\frac{a a_{0}}{0.85252}}}-1\right]=e 63.27074 \tag{14.423}
\end{equation*}
$$

The most convenient way to solve Eq. (14.423) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is:

$$
\begin{equation*}
a=1.47348 a_{0}=7.79733 \times 10^{-11} \mathrm{~m} \tag{14.424}
\end{equation*}
$$

Substitution of Eq. (14.424) into Eq. (14.4129) gives:

$$
\begin{equation*}
c^{\prime}=1.31468 a_{0}=6.95699 \times 10^{-11} \mathrm{~m} \tag{14.425}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.425) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.62936 a_{0}=1.39140 \times 10^{-10} \mathrm{~m} \tag{14.426}
\end{equation*}
$$

The experimental bond distance is [3] :

$$
\begin{equation*}
2 c^{\prime}=1.339 \times 10^{-10} \mathrm{~m} \tag{14.427}
\end{equation*}
$$

Substitution of Eqs. (14.424-14.425) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=0.66540 a_{0}=3.52116 \times 10^{-11} \mathrm{~m} \tag{14.428}
\end{equation*}
$$

Substitution of Eqs. (14.424-14.425) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.89223 \tag{14.429}
\end{equation*}
$$

The nucleus of the C atoms comprise the foci of the $\mathrm{H}_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C_{\text {benzene }} 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). Each benzene carbon atom contributes $(0.75)(-1.13380 \mathrm{eV})=-0.85035 \mathrm{eV}$ (Eqs. (14.483) and (14.493)) to each of the two $C=C$-bond MOs and $(0.5)(-1.13380 \mathrm{eV})=-0.56690 \mathrm{eV}$ (Eq. (14.467)) to the corresponding $C-H$-bond MO. The energy contribution due to the charge donation at each carbon superimposes linearly. The radius of $r_{\text {benzene2sp }}=0.79597 a_{0}$ is calculated using Eq. (14.518) using the total energy donation to each bond with which it is participates in bonding. The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{\text {benzenessp }}=0.79597 a_{0}$ is the radius of the $C_{\text {benzene }} 2 s p^{3}$ shell. Substitution of Eqs. (14.424-14.425) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=134.24^{\circ} \tag{14.430}
\end{equation*}
$$

Then, the angle $\theta_{C=C_{\text {benzene }} 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C=C_{\text {benzene }} 2 s p^{3} H O}=180^{\circ}-134.24^{\circ}=45.76^{\circ} \tag{14.431}
\end{equation*}
$$

as shown in Figure 14.13.
Figure 14.13. The cross section of one $C=C$-bond $\mathrm{MO}(\sigma \mathrm{MO})$ and one $C-H$-bond MO of benzene showing the axes, angles, and point of intersection of each $H_{2}$-type ellipsoidal MO with the corresponding $C_{\text {benzene }} 2 s p^{3}$ HO. The continuation of each $H_{2}$-type-ellipsoidal-MO basis element of the $C=C$ bond and the $C-H$-bond beyond the intersection point with each $C_{\text {benzene }} 2 s p^{3}$ shell and $\sigma \mathrm{MO}$ is shown as dashed since each only serves to solve the energy match with the $C_{\text {benzene }} 2 s p^{3}$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of each intersection point. The actual charge density is shown by the solid lines. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $d_{1}: d_{C=C_{\text {benzene }}, H_{2} M O}, \quad \theta_{1}: \theta_{C=C_{\text {benzene }} 2 s p^{3} H O}, \quad d_{2}: d_{C=C_{\text {benzene }} 2 s p^{3} H O}, \quad R: r_{\text {benzeneC } 2 s p^{3}}, d_{3}: d_{C-H_{\text {benzene }}, H_{2} M O}, \quad \theta_{2}: \theta_{C-H_{\text {benzene }} 2 s p^{3} H O}$, and $d_{4}: d_{C-H_{\text {benzene }} 2 s p^{3} H O}$.

Consider the right-hand intersection point. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$ coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{C=C_{\text {berrene }}, \mathrm{H}_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{\text {benzene2sp }} \sin ^{\sin } \theta_{C=C_{\text {benzene }} 2 s p^{3} H O}=0.79597 a_{0} \sin \theta_{C=C_{\text {benzene }} 2 s p^{3} H O}=b \sin \theta_{C=C_{\text {benzene }}, H_{2} M O} \tag{14.432}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{C=C_{\text {benzene }}, H_{2} M O}=\sin ^{-1} \frac{0.79597 a_{0} \sin \theta_{C=C_{\text {benzene }} 2 s p^{3} H O}}{b}=\sin ^{-1} \frac{0.79597 a_{0} \sin 45.76^{\circ}}{b} \tag{14.433}
\end{equation*}
$$

with the use of Eq. (14.431). Substitution of Eq. (14.428) into Eq. (14.433) gives:

$$
\begin{equation*}
\theta_{C=C_{\text {benzene } e}, H_{2} M O}=58.98^{\circ} \tag{14.434}
\end{equation*}
$$

Then, the distance $d_{C=C_{\text {benzene }}, H_{2} M O}$ along the internuclear axis from the origin of $H_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C=C_{\text {benzene }}, H_{2} M O}=a \cos \theta_{C=C_{\text {benzene }}, H_{2} M O} \tag{14.435}
\end{equation*}
$$

Substitution of Eqs. (14.424) and (14.434) into Eq. (14.435) gives:

$$
\begin{equation*}
d_{C=C_{\text {benzene }}, H_{2} M O}=0.75935 a_{0}=4.01829 \times 10^{-11} \mathrm{~m} \tag{14.436}
\end{equation*}
$$

The distance $d_{C=C_{\text {benzene }} 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by

$$
\begin{equation*}
d_{C=C_{\text {benzene }} 2 s p^{3} H O}=c^{\prime}-d_{C=C_{\text {benzene }}, H_{2} M O} \tag{14.437}
\end{equation*}
$$

Substitution of Eqs. (14.425) and (14.436) into Eq. (14.437) gives:

$$
\begin{equation*}
d_{C=C_{\text {benzene }} 2 s p^{3} H O}=0.55533 a_{0}=2.93870 \times 10^{-11} \mathrm{~m} \tag{14.438}
\end{equation*}
$$

## FORCE BALANCE OF THE $C H$ MOS OF BENZENE

Benzene can also be considered as comprising chemical bonds between six $C H$ radicals wherein each radical comprises a chemical bond between carbon and hydrogen atoms. The solution of the parameters of CH is given in the Hydrogen Carbide ( CH ) section. Each $\mathrm{C}-\mathrm{H}$ bond of CH having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of $75 \% H_{2}$-type ellipsoidal MO and $25 \% \mathrm{C} 2 \mathrm{sp}{ }^{3}$ HO as given by Eq. (13.439):

$$
\begin{equation*}
1 \mathrm{C} 2 s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO} \rightarrow \mathrm{CH} \mathrm{MO} \tag{14.439}
\end{equation*}
$$

The proton of the $H$ atom and the nucleus of the $C$ atom are along each internuclear axis and serve as the foci. As in the case of $H_{2}$, the $\mathrm{C}-\mathrm{H}$-bond MO is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $\mathrm{C} 2 s p^{3}$ HO for distances shorter than the radius of the $C 2 s p^{3}$ shell since it is energetically unfavorable. Thus, each MO surface comprises a prolate spheroid at the $H$ proton that is continuous with the $C 2 s p^{3}$ shell at the $C$ atom whose nucleus serves as the other focus.

The force balance of the CH MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.439) and the energy matching condition between the hydrogen and $C 2 s p^{3} \mathrm{HO}$ components of the MO. The force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ of each $H_{2}$-type-ellipsoidal-MO component of the CH MO in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus $c^{\prime}$ is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $C-H$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the CH MO are solved.

Consider the formation of the double $C=C$-bond MOs of benzene wherein ethylene formed from two $\mathrm{CH}_{2}$ radicals, each having a $C 2 s p^{3}$ shell with an energy given by Eq. (14.146), serves as a basis element. The energy components of $V_{e}, V_{p}$, $T, V_{m}$, and $E_{T}$ are the same as those of the hydrogen carbide radical, except that $E_{T}\left(C=C, 2 s p^{3}\right)$ is subtracted from $E_{T}(C H)$ of Eq. (13.495). As in the case of the $\mathrm{CH}_{2}$ groups of ethylene (Eq. (14.270)), the subtraction of the energy change of the $\mathrm{C} 2 s p^{3}$ shell per $H$ with the formation of the $C=C$-bond MO matches the energy of each $C-H$-bond MO to the decrease in the energy of the corresponding $C 2 s p^{3} \mathrm{HO}$. Using Eqs. (13.431) and (14.247), $E_{T_{\text {benzene }}}(\mathrm{CH})$ is given by:

$$
\begin{equation*}
E_{T_{\text {benzene }}}(C H)=E_{T}+E\left(C, 2 s p^{3}\right)-E_{T}\left(C=C, 2 s p^{3}\right)=\binom{-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]}{-14.63489 \mathrm{eV}-(-1.13379 \mathrm{eV})} \tag{14.440}
\end{equation*}
$$

$E_{T_{\text {benzene }}}(C H)$ given by Eq. (14.440) is set equal to the energy of the $H_{2}$-type ellipsoidal MO given by Eq. (13.75).

$$
\begin{equation*}
E_{T_{\text {benzene }}}(C H)=\binom{-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]}{-14.63489 \mathrm{eV}-(-1.13379 \mathrm{eV})}=-31.63537 \mathrm{eV} \tag{14.441}
\end{equation*}
$$

From the energy relationship given by Eq. (14.441) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the CH MO can be solved.

Substitution of Eq. (13.60) into Eq. (14.441) gives:

$$
\begin{equation*}
\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right]=e 18.13427 \tag{14.442}
\end{equation*}
$$

The most convenient way to solve Eq. (14.442) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is

$$
\begin{equation*}
a=1.60061 a_{0}=8.47006 \times 10^{-11} \mathrm{~m} \tag{14.443}
\end{equation*}
$$

Substitution of Eq. (14.443) into Eq. (14.60) gives:

$$
\begin{equation*}
c^{\prime}=1.03299 a_{0}=5.46636 \times 10^{-11} \mathrm{~m} \tag{14.444}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.444) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.06598 a_{0}=1.09327 \times 10^{-10} \mathrm{~m} \tag{14.445}
\end{equation*}
$$

The experimental bond distance is [3]:

$$
\begin{equation*}
2 c^{\prime}=1.101 \times 10^{-10} \mathrm{~m} \tag{14.446}
\end{equation*}
$$

Substitution of Eqs. (14.443-14.444) into Eq. (14.62) gives:

$$
\begin{equation*}
b=c=1.22265 a_{0}=6.47000 \times 10^{-11} \mathrm{~m} \tag{14.447}
\end{equation*}
$$

Substitution of Eqs. (14.443-14.444) into Eq. (14.63) gives:

$$
\begin{equation*}
e=0.64537 \tag{14.448}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $C$ atom comprise the foci of each $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C_{\text {benzene }} 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{\text {benzene2sp }}=0.79597 a_{0}$ is the radius of the $C_{\text {benzene }} 2 s p^{3}$ shell. Substitution of Eqs. (14.443-14.444) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=74.42^{\circ} \tag{14.449}
\end{equation*}
$$

Then, the angle $\theta_{C-H_{\text {benzene }} 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C-H_{\text {benzene }} 2 s p^{3} H O}=180^{\circ}-74.42^{\circ}=105.58^{\circ} \tag{14.450}
\end{equation*}
$$

as shown in Figure 14.14.
Figure 14.14. The cross section of one $C-H$-bond MO of benzene showing the axes, angles, and point of intersection of the $H_{2}$-type ellipsoidal MO with the $C_{\text {benzene }} 2 s p^{3} \mathrm{HO}$. The continuation of the $H_{2}$-type-ellipsoidal-MO basis element beyond the intersection point with the $C_{\text {benzene }} 2 s p^{3}$ shell is shown as dashed since it only serves to solve the energy match with the $C_{\text {benzene }} 2 s p^{3}$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of the intersection point. The actual charge density is shown by the solid lines. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $d_{1}: d_{C-H_{\text {benzene }}, H_{2} M O}, \theta_{1}: \theta_{C-H_{\text {benzene }} 2 s p^{3} H O}, d_{2}: d_{C-H_{\text {benzene }} 2 s p^{3} H O}$, and $R: r_{\text {benzene2sp }}{ }^{3}$

The Cartesian i-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{C-H_{b e n z e n e}, H_{2} M O}$ satisfies the following relationship:
such that

$$
\begin{equation*}
\theta_{C-H_{\text {benzene }}, H_{2} M O}=\sin ^{-1} \frac{0.79597 a_{0} \sin \theta_{C-H_{\text {benzene }} 2 s p^{3} H O}}{b}=\sin ^{-1} \frac{0.79597 a_{0} \sin 105.58^{\circ}}{b} \tag{14.452}
\end{equation*}
$$

with the use of Eq. (14.450). Substitution of Eq. (14.447) into Eq. (14.452) gives:

$$
\begin{equation*}
\theta_{C-H_{\text {benzene }}, H_{2} M O}=38.84^{\circ} \tag{14.453}
\end{equation*}
$$

Then, the distance $d_{C-H_{\text {benzene }}, H_{2} M O}$ along the internuclear axis from the origin of $H_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C-\mathrm{H}_{\text {benzene }}, \mathrm{H}_{2} \mathrm{MO}}=a \cos \theta_{C-\mathrm{H}_{\text {benzene }}, \mathrm{H}_{2} \mathrm{MO}} \tag{14.454}
\end{equation*}
$$

Substitution of Eqs. (14.443) and (14.453) into Eq. (14.454) gives:

$$
\begin{equation*}
d_{C-H_{\text {benzene } e}, H_{2} M O}=1.24678 a_{0}=6.59767 \times 10^{-11} \mathrm{~m} \tag{14.455}
\end{equation*}
$$

The distance $d_{C-H_{\text {benzene }} 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C-H_{\text {benzene }} 2 s p^{3} \mathrm{HO}}=d_{C-\mathrm{H}_{\text {benzene }}, \mathrm{H}_{2} \mathrm{MO}}-c^{\prime} \tag{14.456}
\end{equation*}
$$

Substitution of Eqs. (14.444) and (14.455) into Eq. (14.456) gives:

$$
\begin{equation*}
d_{C-H_{\text {benzene }} 2 s p^{3} H O}=0.21379 a_{0}=1.13131 \times 10^{-11} \mathrm{~m} \tag{14.457}
\end{equation*}
$$

The basis set of benzene, the ethylene molecule, is planar with bond angles of approximately $120^{\circ}$ (Eqs. (14.298-14.302)). To form a closed ring of equivalent planar bonds, the $C=C$ bonds of benzene form a planar hexagon. The bond angle $\theta_{C=C=C}$ between the internuclear axis of any two adjacent $C=C$ bonds is:

$$
\begin{equation*}
\theta_{C=C=C}=120^{\circ} \tag{14.458}
\end{equation*}
$$

The bond angle $\theta_{C=C-H}$ between the internuclear axis of each $C=C$ bond and the corresponding $H$ atom of each $C H$ group is

$$
\begin{equation*}
\theta_{C=C-H}=120^{\circ} \tag{14.459}
\end{equation*}
$$

The experimental angle between the $C=C=C$ bonds is [13-15]:

$$
\begin{equation*}
\theta_{C=C=C}=120^{\circ} \tag{14.460}
\end{equation*}
$$

The experimental angle between the $C=C-H$ bonds is [13-15]:

$$
\begin{equation*}
\theta_{C=C-H}=120^{\circ} \tag{14.461}
\end{equation*}
$$

The $C_{6} H_{6}$ MO shown in Figure 14.15 was rendered using these parameters.
The charge-density in the $C=C$-bond MO is increased by a factor of 0.25 per bond with the formation of the $C_{\text {benzene }} 2 s p^{3}$ HOs each having a smaller radius. Using the orbital composition of the $C H$ groups (Eq. (14.439)) and the $C=C$ bond MO (Eq. (14.416)), the radii of $C 1 s=0.17113 a_{0}$ (Eq. (10.51)) and $C_{\text {benzene }} 2 s p^{3}=0.79597 a_{0}$ (Eq. (14.520)) shells, and the parameters of the $C=C$-bond (Eqs. (13.3-13.4), (14.424-14.426), and (14.428-14.438)), the parameters of the $C-H$-bond MOs (Eqs. (13.3-13.4), (14.443-14.445), and (14.447-14.457)), and the bond-angle parameters (Eqs. (14.458-14.459)), the charge-density of the $C_{6} H_{6}$ MO comprising the linear combination of six sets of $C-H$-bond MOs with bridging $C \stackrel{3 e}{=} C$-bond MOs is shown in Figure 14.15. Each $\mathrm{C}-\mathrm{H}$-bond MO comprises a $H_{2}$-type ellipsoidal MO and a $C_{\text {benzene }} 2 s p^{3} \mathrm{HO}$ having the dimensional diagram shown in Figure 14.14. The $C=C$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two sets of two $C_{\text {benzene }} 2 s p^{3}$ HOs having the dimensional diagram shown in Figure 14.13.

Figure 14.15. $C_{6} H_{6}$ MO comprising the linear combination of six sets of $C-H$-bond MOs bridged by $C=C$-bond MOs.
(A) Color scale, translucent view of the charge-density of the $C_{6} H_{6}$-bond MO with each $C_{\text {benzene }} 2 s p^{3}$ HOs shown transparently. Each $C=C$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two pairs of $C_{\text {benzene }} 2 s p^{3}$ HOs. For each $C-H$ and $C=C$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {benzene }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {benzene }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown. (B)-(D) End-on view, translucent view high-lighting each $C=C$-bond MO, and opaque view of the charge-density of the $C_{6} H_{6} \mathrm{MO}$, respectively.

## ENERGIES OF THE CH GROUPS

The energies of each CH group of benzene are given by the substitution of the semiprincipal axes (Eqs. (14.443-14.444) and (14.447)) into the energy equations of hydrogen carbide (Eqs. (13.449-13.453)), with the exception that $E_{T}\left(C=C, 2 s p^{3}\right)$ (Eq. (14.247)) is subtracted from $E_{T}(C H)$ in Eq. (13.453).

$$
\begin{equation*}
V_{e}=(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-37.10024 \mathrm{eV} \tag{14.462}
\end{equation*}
$$

$$
\begin{equation*}
V_{p}=\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=13.17125 \mathrm{eV} \tag{14.463}
\end{equation*}
$$

$$
\begin{equation*}
T=(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=11.58941 \mathrm{eV} \tag{14.464}
\end{equation*}
$$

$$
\begin{equation*}
V_{m}=(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-5.79470 \mathrm{eV} \tag{14.465}
\end{equation*}
$$

$$
\begin{equation*}
E_{T_{\text {benzene }}}(C H)=\binom{-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]}{-14.63489 \mathrm{eV}-(-1.13379 \mathrm{eV})}=-31.63539 \mathrm{eV} \tag{14.466}
\end{equation*}
$$

where $E_{T_{\text {benzene }}}(C H)$ is given by Eq. (14.440) which is reiteratively matched to Eq. (13.75) within five-significant-figure round off error.

The total energy of the $C-H$-bond MO, $E_{T_{\text {benzene }}}(C-H)$, is given by the sum of $0.5 E_{T}\left(C=C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell per single bond due to the decrease in radius with the formation of the corresponding $C=C$-bond MO (Eq. (14.247)), and $E_{T_{\text {benzene }}}(C H)$, the $\sigma$ MO contribution given by Eq. (14.441).

$$
\begin{align*}
E_{T_{\text {benzene }}}(C-H) & =(0.5) E_{T}\left(C=C, 2 s p^{3}\right)+E_{T_{\text {benzene }}}(C H) \\
& =\left(\begin{array}{l}
(0.5)(-1.13379 \mathrm{eV})+ \\
\binom{\left.-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]\right)}{-14.63489 \mathrm{eV}-(-1.13379 \mathrm{eV})} \\
\\
\end{array}\right)  \tag{14.467}\\
& =-32.20226 \mathrm{eV}
\end{align*}
$$

## VIBRATION OF THE ${ }^{12} \mathrm{CH}$ GROUPS

The vibrational energy levels of CH in benzene may be solved using the methods given in the Vibration and Rotation of CH section.

## THE DOPPLER ENERGY TERMS OF THE ${ }^{12} \mathrm{CH}$ GROUPS

The equations of the radiation reaction force of the $C H$ groups in benzene are the same as those of the hydrogen carbide radical with the substitution of the CH -group parameters. Using Eq. (13.477), the angular frequency of the reentrant oscillation in the transition state is

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=2.64826 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{14.468}
\end{equation*}
$$

where $b$ is given by Eq. (14.447). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 2.64826 \times 10^{16} \mathrm{rad} / \mathrm{s}=17.43132 \mathrm{eV} \tag{14.469}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each $H_{2}$-type MO, for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.469) for $\bar{E}_{K}$ gives the Doppler energy of the electrons for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h v} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-31.63537 \mathrm{eV} \sqrt{\frac{2 e(17.43132 \mathrm{eV})}{m_{e} c^{2}}}=-0.26130 \mathrm{eV} \tag{14.470}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of CH due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.470) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of the $C-H$ bond. Using $\omega_{e}$ given by Eq. (13.458) for $\bar{E}_{\text {Kvib }}$ of the transition, $\bar{E}_{\text {benzene osc }}\left({ }^{12} \mathrm{CH}\right)$ per bond is:

$$
\begin{align*}
& \bar{E}_{\text {benzene osc }}\left({ }^{12} \mathrm{CH}\right)=\bar{E}_{D}+\bar{E}_{\text {Kvib }}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{14.471}\\
& \bar{E}_{\text {benzene osc }}\left({ }^{12} \mathrm{CH}\right)=-0.26130 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})=-0.08364 \mathrm{eV} \tag{14.472}
\end{align*}
$$

## TOTAL AND BOND ENERGIES OF THE ${ }^{12} \mathrm{CH}$ GROUPS

$E_{\text {benzeneT+osc }}\left({ }^{12} \mathrm{CH}\right)$, the total energy of each ${ }^{12} \mathrm{CH}$ group including the Doppler term, is given by the sum of $E_{T_{\text {benzene }}}(\mathrm{C}-\mathrm{H})$ (Eq. (14.467)) and $\bar{E}_{\text {benzene osc }}\left({ }^{12} \mathrm{CH}\right)$ given by Eq. (14.472).

$$
\begin{align*}
E_{\text {benzeneT +osc }}\left({ }^{12} C H\right) & =\binom{\left(V_{e}+T+V_{m}+V_{p}+E\left(C, 2 s p^{3}\right)-E_{T}\left(C=C, 2 s p^{3}\right)\right)}{+0.5 E_{T}\left(C=C, 2 s p^{3}\right)+\bar{E}_{\text {benzene osc }}\left({ }^{12} \mathrm{CH}\right)}  \tag{14.473}\\
& =E_{T_{\text {benzzene }}}(C-H)+\bar{E}_{\text {benzene osc }}\left({ }^{12} \mathrm{CH}\right)
\end{align*}
$$

$$
\left.\begin{array}{rl}
E_{\text {benzeneT Tosc }}\left({ }^{12} \mathrm{CH}\right) & \left.=\left\{\begin{array}{l}
\binom{\frac{-e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]}{-14.63489 \mathrm{eV}-(-1.13379 \mathrm{eV})}-0.5(1.13379 \mathrm{eV}) \\
-(31.63536831 \mathrm{eV}) \sqrt{\frac{\sqrt{\frac{3}{4} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}}{m_{e}}} \\
m_{e} c^{2} \\
\hline
\end{array}\right] \sqrt{\frac{1}{2} \hbar}\right) \tag{14.474}
\end{array}\right\}
$$

From Eqs. (14.472-14.474), the total energy of each ${ }^{12} \mathrm{CH}$ is:

$$
\begin{align*}
E_{\text {benzeneT +osc }}\left({ }^{12} \mathrm{CH}\right) & =-32.20226 \mathrm{eV}+\bar{E}_{\text {benzene osc }}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =-32.20226 \mathrm{eV}-\left(0.26130 \mathrm{eV}-\frac{1}{2}(0.35532 \mathrm{eV})\right)  \tag{14.475}\\
& =-32.28590 \mathrm{eV}
\end{align*}
$$

where $\omega_{e}$ given by Eq. (13.458) was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
As in the case of ${ }^{12} \mathrm{CH}_{2},{ }^{14} \mathrm{NH}$, and acetylene, the dissociation of the $\mathrm{C}=\mathrm{C}$ bonds forms three unpaired electrons per central atom wherein the magnetic moments cannot all cancel. The energy per atom $E$ (magnetic) is given by Eq. (13.524). Thus, the bond dissociation energy of each CH group of the linear combination to form benzene, $E_{D_{\text {benzene }}}\left({ }^{12} \mathrm{CH}\right)$, is given by the sum of the total energies of the $C 2 s p^{3} \mathrm{HO}$ and the hydrogen atom minus the sum of $E_{\text {benzeneT+osc }}\left({ }^{12} \mathrm{CH}\right)$ and E (magnetic) given by Eq. (13.524):

$$
\begin{equation*}
E_{D_{\text {benzene }}}\left({ }^{12} \mathrm{CH}\right)=E\left(\mathrm{C}, 2 s p^{3}\right)+E(H)-\left(E_{\text {benzeneT }+ \text { osc }}\left({ }^{12} \mathrm{CH}\right)+E(\text { magnetic })\right) \tag{14.476}
\end{equation*}
$$

$E\left(C, 2 s p^{3}\right)$ is given by Eq. (13.428), $E_{D}(H)$ is given by Eq. (13.154), and $E$ (magnetic) is given by Eq. (13.524). Thus, $E_{D_{\text {benzene }}}\left({ }^{12} \mathrm{CH}\right)$ given by Eqs. (13.154), (13.428), (13.524), (14.475), and (14.476) is:

$$
\begin{align*}
E_{D_{\text {benzene }}}\left({ }^{12} \mathrm{CH}\right) & =-(14.63489 \mathrm{eV}+13.59844 \mathrm{eV})-\left(E_{\text {benzeneT +osc }}(\mathrm{CH})+E(\text { magnetic })\right) \\
& =-28.23333 \mathrm{eV}-(-32.28590 \mathrm{eV}+0.14803 \mathrm{eV})  \tag{14.477}\\
& =3.90454 \mathrm{eV}
\end{align*}
$$

## SUM OF THE ENERGIES OF THE $C=C \quad \sigma$ MO ELEMENT AND THE HOs OF BENZENE

The energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ of the $\mathrm{C}=\mathrm{C}$-bond MO of benzene are the same as those of the $\mathrm{CH}_{2} \mathrm{CH}_{2}$ MO except that the hybridization factor is given by Eq. (14.417). The energies of each $C=C$-bond MO are given by the substitution of the semiprincipal axes (Eqs. (14.424-14.425) and (14.428)) into energy equations of the $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{MO}$ (Eqs. (14.319-14.323)), with the exception that the hybridization factor is 0.85252 (Eq. (14.417)).

$$
\begin{align*}
& V_{e}=2(0.85252) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-101.12679 \mathrm{eV}  \tag{14.478}\\
& V_{p}=2 \frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=20.69825 \mathrm{eV}  \tag{14.479}\\
& T=2(0.85252) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=34.31559 \mathrm{eV}  \tag{14.480}\\
& V_{m}=2(0.85252) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-17.15779 \mathrm{eV}  \tag{14.481}\\
& E_{T}(C=C, \sigma)=-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.85252)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]=-63.27075 \mathrm{eV} \tag{14.482}
\end{align*}
$$

where $E_{T}(C=C, \sigma)$ is the total energy of the $C=C \quad \sigma$ MO given by Eq. (14.421) which is reiteratively matched to two times Eq. (13.75) within five-significant-figure round off error.

The total energy of the $C=C$-bond MO, $E_{T}(C=C)$, is given by the sum of two times $E_{T}\left(C=C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell due to the decrease in radius with the formation of the $C=C$-bond MO (Eq. (14.247)), and $E_{T}(C=C, \sigma)$, the $\sigma$ MO contribution given by Eq. (14.422).

$$
\begin{align*}
E_{T}(C=C) & =2 E_{T}\left(C=C, 2 s p^{3}\right)+E_{T}(C=C, \sigma) \\
& =\left(\left(-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.85252)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]\right)\right)  \tag{14.483}\\
& =2(-1.13380 \mathrm{eV})+(-63.27074 \mathrm{eV})=-65.53833 \mathrm{eV}
\end{align*}
$$

which is the same $E_{T}(C=C, \sigma)$ of ethylene given by Eq. (14.324).

## VIBRATION OF BENZENE

The $C=C$ vibrational energy levels of $C_{6} H_{6}$ may be solved as six sets of equivalent coupled harmonic oscillators where each $C$ is further coupled to the corresponding $C-H$ oscillator by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERMS OF THE $C=C$-BOND MO ELEMENT OF BENZENE

The equations of the radiation reaction force of the $C=C$-bond MO of benzene are given by Eq. (13.142), except the forceconstant factor is ( 0.85252 ) 0.5 based on the force constant $k^{\prime}$ of Eq. (14.418), and the $C=C$-bond MO parameters are used. The angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{0.85252 \frac{(0.5) e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=4.97272 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{14.484}
\end{equation*}
$$

where $b$ is given by Eq. (14.428). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 4.97272 \times 10^{16} \mathrm{rad} / \mathrm{s}=32.73133 \mathrm{eV} \tag{14.485}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each $H_{2}$-type MO, for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.485) for $\bar{E}_{K}$ gives the Doppler energy of the electrons for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-31.63536831 \mathrm{eV} \sqrt{\frac{2 e(32.73133 \mathrm{eV})}{m_{e} c^{2}}}=-0.35806 \mathrm{eV} \tag{14.486}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $C=C$-bond MO due to the reentrant orbit of the bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{o s c}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.486) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of the $C=C$ bond. Using the experimental $C=C E_{v i b}\left(v_{16}\right)$ of $1584.8 \mathrm{~cm}^{-1}(0.19649 \mathrm{eV})$ [16] for $\bar{E}_{\text {Kvib }}$ of the transition state having two bonds, $\bar{E}_{\text {osc }}^{\prime}(C=C, \sigma)$ per bond is:

$$
\begin{align*}
& \bar{E}_{o s c}^{\prime}(C=C, \sigma)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{14.487}\\
& \bar{E}_{o s c}^{\prime}(C=C, \sigma)=-0.35806 \mathrm{eV}+\frac{1}{2}(0.19649 \mathrm{eV})=-0.25982 \mathrm{eV} \tag{14.488}
\end{align*}
$$

Given that the vibration and reentrant oscillation is for two $C-C$ bonds of each $C=C$ double bond, $\bar{E}_{\text {benzene osc }}(C=C, \sigma)$, is:

$$
\begin{equation*}
\bar{E}_{\text {benzene osc }}(C=C, \sigma)=2\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)=2\left(-0.35806 \mathrm{eV}+\frac{1}{2}(0.19649 \mathrm{eV})\right)=-0.51963 \mathrm{eV} \tag{14.489}
\end{equation*}
$$

## TOTAL ENERGIES OF THE $C=C$-BOND MO ELEMENT OF BENZENE

$E_{T+o s c}(C=C)$, the total energy of the $C=C$-bond MO of benzene including the Doppler term, is given by the sum of $E_{T}(C=C)$ (Eq. (14.483)) and $\bar{E}_{\text {benzene osc }}(C=C, \sigma)$ given by Eq. (14.489).

$$
\begin{align*}
E_{T+\text { osc }}(C=C) & =V_{e}+T+V_{m}+V_{p}+2 E_{T}\left(C=C, 2 s p^{3}\right)+\bar{E}_{\text {benzene osc }}(C=C, \sigma) \\
& =E_{T}(C=C, \sigma)+2 E_{T}\left(C=C, 2 s p^{3}\right)+\bar{E}_{\text {benzene osc }}(C=C, \sigma)  \tag{14.490}\\
& =E_{T}(C=C)+\bar{E}_{\text {benzene osc }}(C=C, \sigma) \\
& \left(\frac{-2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.85252)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]+2 E_{T}\left(C=C, 2 s p^{3}\right)\right)  \tag{14.491}\\
E_{T+\text { osc }}(C=C) & =\left\{\begin{array}{l}
\left.(31.63536831 \mathrm{eV}) \sqrt{\frac{\left(0 \hbar \sqrt{\frac{(0.85252) \frac{1}{2} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}\right.}{m_{e} c^{2}}}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{array}\right\} \\
& =-65.53833 \mathrm{eV}-2\left(0.35806 \mathrm{eV}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{align*}
$$

From Eqs. (14.489-14.491), the total energy of the $C=C$-bond MO is:

$$
\begin{align*}
E_{T+\text { osc }}(C=C) & =-63.27074 \mathrm{eV}+2 E_{T}\left(C=C, 2 s p^{3}\right)+\bar{E}_{\text {benzene osc }}(C=C, \sigma) \\
& =-63.27074 \mathrm{eV}+2(-1.13380 \mathrm{eV})-2\left(0.35806 \mathrm{eV}-\frac{1}{2}(0.19649 \mathrm{eV})\right)  \tag{14.492}\\
& =-66.05796 \mathrm{eV}
\end{align*}
$$

where the experimental $E_{v i b}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.

## TOTAL BOND DISSOCIATION ENERGY OF BENZENE

Ethylene serves as a basis element for the $C=C$ bonding of benzene wherein each of the six $C=C$ bonds of benzene comprises $(0.75)(4)=3$ electrons according to Eq. (14.416). The total energy of the bonds of the eighteen electrons of the $C=C$ bonds of benzene, $E_{T}\left(C_{6} H_{6}, C=\frac{3 e}{=} C\right)$, is given by (6)(0.75) times $E_{T+o s c}(C=C)$ (Eq. (14.492)), the total energy of the $C=C$-bond MO of benzene including the Doppler term, minus eighteen times $E\left(C, 2 s p^{3}\right)$ (Eq. (14.146)), the initial energy of each $C 2 s p^{3} \mathrm{HO}$ of each $C$ that forms the double $C=C$ bonds. Thus, the total energy of the six $C \stackrel{3 e}{=} C$ bonds of benzene is:

$$
\begin{align*}
E_{T}\left(C_{6} H_{6}, C \stackrel{3 e}{=} C\right) & =(6)(0.75) E_{T+o s c}(C=C)-18 E\left(C, 2 s p^{3}\right) \\
& =(6)(0.75)(-66.05796 \mathrm{eV})-18(-14.63489 \mathrm{eV})  \tag{14.493}\\
& =-297.26081 \mathrm{eV}-(-263.42798 \mathrm{eV}) \\
& =-33.83284 \mathrm{eV}
\end{align*}
$$

Each of the $C-H$ bonds of benzene comprises two electrons according to Eq. (14.439). From the energy of each $C-H$ bond, $-E_{D_{\text {benereere }}}\left({ }^{12} \mathrm{CH}\right)$ (Eq. (14.477)), the total energy of the twelve electrons of the six $C-H$ bonds of benzene, $E_{T}\left(C_{6} H_{6}, C-H\right)$, is given by:

$$
\begin{equation*}
E_{T}\left(C_{6} H_{6}, \mathrm{C}-\mathrm{H}\right)=(6)\left(-E_{D_{\text {bererene }}}\left({ }^{12} \mathrm{CH}\right)\right)=6(-3.90454 \mathrm{eV})=-23.42724 \mathrm{eV} \tag{14.494}
\end{equation*}
$$

The total bond dissociation energy of benzene, $E_{D}\left(C_{6} H_{6}\right)$, is given by the negative sum of $E_{T}\left(C_{6} H_{6}, C \stackrel{3 e}{=} C\right)$ (Eq. (14.493)) and $E_{T}\left(C_{6} H_{6}, C-H\right)($ Eq. (14.494)):

$$
\begin{align*}
E_{D}\left(C_{6} H_{6}\right) & =-\left(E_{T}\left(C_{6} H_{6}, C=C\right)+E_{T}\left(C_{6} H_{6}, C-H\right)\right)  \tag{14.495}\\
& =-((-33.83284 \mathrm{eV})+(-23.42724 \mathrm{eV}))=57.2601 \mathrm{eV}
\end{align*}
$$

The experimental total bond dissociation energy of benzene, $E_{T}\left(C_{6} H_{6}\right)$, is given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\right.$ (benzene $($ gas $\left.)\right)$ ) and the sum of the enthalpy of the formation of the gaseous carbons $\left(\Delta H_{f}(C(g a s))\right)$ and hydrogen $\left(\Delta H_{f}(H(g a s))\right)$ atoms. The heats of formation are [17-18]:

$$
\begin{align*}
& \Delta H_{f}(\text { benzene }(\text { gas }))=82.9 \mathrm{~kJ} / \text { mole }(0.8592 \mathrm{eV} / \text { molecule })  \tag{14.496}\\
& \Delta H_{f}(C(\text { gas }))=716.68 \mathrm{~kJ} / \text { mole }(7.42774 \mathrm{eV} / \text { atom })  \tag{14.497}\\
& \Delta H_{f}(H(\text { gas }))=217.998 \mathrm{~kJ} / \text { mole }(2.259353 \mathrm{eV} / \text { atom }) \tag{14.498}
\end{align*}
$$

thus, the total bond dissociation energy of benzene, $E_{D}\left(C_{6} H_{6}\right)$, is:

$$
\begin{align*}
E_{D}\left(C_{6} H_{6}\right)-E_{T}\left(C_{6} H_{6}\right) & =-\left(\Delta H_{f}(\text { benzene }(\text { gas }))-\left(6 \Delta H_{f}(C(\operatorname{gas}))+6 \Delta H_{f}(H(\operatorname{gas}))\right)\right) \\
& =-(0.8592 \mathrm{eV}-6(7.42774 \mathrm{eV}+2.259353 \mathrm{eV}))  \tag{14.499}\\
& =57.26 \mathrm{eV}
\end{align*}
$$

where $E_{T}\left(C_{6} H_{6}\right)$ is the total energy of the bonds. The results of the determination of bond parameters of $C_{6} H_{6}$ are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

## CONTINUOUS-CHAIN ALKANES ( $\left.C_{n} H_{2 n+2}, n=3,4,5 \ldots \infty\right)$

The continuous chain alkanes, $C_{n} H_{2 n+2}$, are the homologous series comprising terminal methyl groups at each end of the chain with $n-2$ methylene $\left(\mathrm{CH}_{2}\right)$ groups in between:

$$
\begin{equation*}
\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{n-2} \mathrm{CH}_{3} \tag{14.500}
\end{equation*}
$$

$C_{n} H_{2 n+2}$ can be solved using the same principles as those used to solve ethane and ethylene wherein the $2 s$ and $2 p$ shells of each $C$ hybridize to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. Three $H$ AOs combine with three carbon $2 s p^{3}$ HOs and two $H$ AOs combine with two carbon $2 s p^{3}$ HOs to form each methyl and methylene group, respectively, where each bond comprises a $H_{2}$-type MO developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section. The $\mathrm{CH}_{3}$ and $\mathrm{CH}_{2}$ groups bond by forming $\mathrm{H}_{2}$-type MOs between the remaining $C 2 s p^{3}$ HOs on the carbons such that each carbon forms four bonds involving its four $C 2 s p^{3}$ HOs.

## FORCE BALANCE OF THE $C-C$-BOND MOs OF CONTINUOUS-CHAIN ALKANES

$C_{n} H_{2 n+2}$ comprises a chemical bond between two terminal $\mathrm{CH}_{3}$ radicals and $n-2 \mathrm{CH}_{2}$ radicals wherein each methyl and methylene radical comprises three and two chemical bonds, respectively, between carbon and hydrogen atoms. The solution of the parameters of $\mathrm{CH}_{3}$ is given in the Methyl Radical $\left(\mathrm{CH}_{3}\right)$ section. The solution of the parameters of $\mathrm{CH}_{2}$ is given in the Dihydrogen Carbide Radical $\left(\mathrm{CH}_{2}\right)$ section and follows the same procedure. Each $\mathrm{C}-\mathrm{H}$ bond having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of $75 \% \mathrm{H}_{2}$-type ellipsoidal MO and $25 \% \mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO}$ as given by Eq. (13.429):

$$
\begin{equation*}
1 \mathrm{C} 2 s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO} \rightarrow \mathrm{C}-\mathrm{H} \mathrm{MO} \tag{14.501}
\end{equation*}
$$

The proton of the $H$ atom and the nucleus of the $C$ atom are along each internuclear axis and serve as the foci. As in the case of $H_{2}$, each of the $\mathrm{C}-\mathrm{H}$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $C 2 s p^{3}$ HO for distances shorter than the radius of the $C 2 s p^{3}$ shell since it is energetically unfavorable. Thus, each MO surface comprises a prolate spheroid at the $H$ proton that is continuous with the $C 2 s p^{3}$ shell at the $C$ atom whose nucleus serves as the other focus. The electron configuration and the energy, $E\left(C, 2 s p^{3}\right)$, of the $C 2 s p^{3}$ shell is given by Eqs. (13.422) and (13.428), respectively. The central paramagnetic force due to spin of each $\mathrm{C}-H$ bond is provided by the spin-pairing force of the $\mathrm{CH}_{3}$ or $\mathrm{CH}_{2} \mathrm{MO}$ that has the symmetry of an $s$ orbital that superimposes with the $C 2 s p^{3}$ orbitals such that the corresponding angular momenta are unchanged. The energies of each $\mathrm{CH}_{3}$ and $\mathrm{CH}_{2} \mathrm{MO}$ involve each $\mathrm{C} 2 s p^{3}$ and each $\mathrm{H} 1 s$ electron with the formation of each $C-H$ bond. The sum of the energies of the $H_{2}$-type ellipsoidal MOs is matched to that of the $C 2 s p^{3}$ shell.

The force balance of the $C-H$-bond MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.139) and the energy matching condition between the $C 2 s p^{3}-\mathrm{HO}$ components of the MO.

The $\mathrm{CH}_{3}$ and $\mathrm{CH}_{2}$ groups form $\mathrm{C}-\mathrm{C}$ bonds comprising $\mathrm{H}_{2}$-type MOs between the remaining $\mathrm{C} 2 s p^{3} \mathrm{HOs}$ on the carbons such that each carbon forms four bonds involving its four $C 2 s p^{3} \mathrm{HOs}$. The sharing of electrons between any two $C 2 s p^{3} \mathrm{HOs}$ to form a molecular orbital (MO) comprising two spin-paired electrons permits each $C 2 s p^{3} \mathrm{HO}$ to decrease in radius and energy. As in the case of the $C-H$ bonds, each $C-C$-bond MO is a prolate-spheroidal-MO surface that cannot extend into $C 2 s p^{3} \mathrm{HO}$ for distances shorter than the radius of the $C 2 s p^{3}$ shell of each atom. Thus, the MO surface comprises a partial prolate spheroid in between the carbon nuclei and is continuous with the $C 2 s p^{3}$ shell at each $C$ atom. The energy of the $H_{2}$-type ellipsoidal MO is matched to that of the $C 2 s p^{3}$ shell. As in the case of previous examples of energy-matched MOs such as the $C-C$-bond MO of ethane, each $C-C$-bond MO of $C_{n} H_{2 n+2}$ must comprise $75 \%$ of a $H_{2}$-type ellipsoidal MO in order to match potential, kinetic, and orbital energy relationships. Thus, the $C-C$-bond MO must comprise two $C 2 s p^{3} \mathrm{HOs}$ and $75 \%$ of a $H_{2}$-type ellipsoidal MO divided between the two $C 2 s p^{3}$ HOs:
$2 \mathrm{C} 2 \mathrm{sp}^{3}+0.75 \mathrm{H}_{2} \mathrm{MO} \rightarrow \mathrm{C}-\mathrm{C}$ - bond MO
The linear combination of the $\mathrm{H}_{2}$-type ellipsoidal MO with each $C 2 s p^{3} \mathrm{HO}$ further comprises an excess $25 \%$ charge-density contribution from each $C 2 s p^{3} \mathrm{HO}$ to the $C-C$-bond MO to achieve an energy minimum. The force balance of the $C-C$-bond MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.502) and the energy matching condition between the $C 2 s p^{3}-\mathrm{HO}$ components of the MO.

Before bonding, the $2 s p^{3}$ hybridized orbital arrangement of each carbon atom is given by Eq. (14.140). The sum $E_{T}\left(C, 2 s p^{3}\right)$ of calculated energies of $C, C^{+}, C^{2+}$, and $C^{3+}$ is given by Eq. (14.141). The radius $r_{2 s p^{3}}$ of the $C 2 s p^{3}$ shell is given by Eq. (14.142). The Coulombic energy $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ and the energy $E\left(C, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell are given by Eqs. (14.143) and (14.146), respectively.

The formation of each $\mathrm{C}-\mathrm{C}$ bond of $C_{n} H_{2 n+2}$ further requires that the energy of all $H_{2}$-type prolate spheroidal MOs ( $\sigma$ MOs ) be matched at all $C 2 s p^{3} \mathrm{HOs}$ since they are continuous throughout the molecule. Thus, the energy of each $C 2 s p^{3} \mathrm{HO}$ must be a linear combination of that of the $\mathrm{CH}_{3}$ and $\mathrm{CH}_{2}$ groups that serve as basis elements. Each $\mathrm{CH}_{3}$ forms one $\mathrm{C}-\mathrm{C}$ bond, and each $\mathrm{CH}_{2}$ group forms two. Thus, the energy of each $\mathrm{C} 2 s p^{3} \mathrm{HO}$ of each $\mathrm{CH}_{3}$ and $\mathrm{CH}_{2}$ group alone is given by that in ethane and ethylene, respectively. The parameters of ethane and ethylene are given by Eqs. (14.147-14.151) and (14.24414.247), respectively. The alkane parameters can be determined by first reviewing those of ethane and ethylene.

With the formation of the $C-C$-bond MO of ethane from two methyl radicals, each having a $C 2 s p^{3}$ electron with an energy given by Eq. (14.146), the total energy of the state is given by the sum over the four electrons. The sum $E_{T}\left(C_{\text {ethane }}, 2 s p^{3}\right)$ of calculated energies of $C 2 s p^{3}, C^{+}, C^{2+}$, and $C^{3+}$ given by Eq. (14.147), is:

$$
\begin{align*}
E_{T}\left(C_{\text {ehane }}, 2 s p^{3}\right) & =-\left(64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+E\left(C, 2 s p^{3}\right)\right) \\
& =-(64.3921 \mathrm{eV}+48.3125 \mathrm{eV}+24.2762 \mathrm{eV}+14.63489 \mathrm{eV})  \tag{14.503}\\
& =-151.61569 \mathrm{eV}
\end{align*}
$$

where $E\left(C, 2 s p^{3}\right)$ is the sum of the energy of $C,-11.27671 \mathrm{eV}$, and the hybridization energy. The orbital-angular-momentum interactions also cancel such that the energy of the $E_{T}\left(C_{\text {ehane }}, 2 s p^{3}\right)$ is purely Coulombic.

The sharing of electrons between two $C 2 s p^{3}$ HOs to form a $C-C$-bond MO permits each participating hybridized orbital to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each $C 2 s p^{3} \mathrm{HO}$ donates an excess of $25 \%$ of its electron density to the $C-C$-bond MO to form an energy minimum. By considering this electron redistribution in the ethane molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{\text {ethane } 2 s p^{3}}$ of the $C 2 s p^{3}$ shell of ethane may be calculated from the Coulombic energy using Eq. (10.102).

$$
\begin{equation*}
r_{\text {ethane } 2 s p^{3}}=\left(\sum_{n=2}^{5}(Z-n)-0.25\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 151.61569 \mathrm{eV})}=\frac{9.75 e^{2}}{8 \pi \varepsilon_{0}(e 151.61569 \mathrm{eV})}=0.87495 a_{0} \tag{14.504}
\end{equation*}
$$

using Eqs. (10.102) and (14.504), the Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {ethane }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(C_{\text {ethane }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {ehane2sp }}{ }^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.87495 a_{0}}=-15.55033 \mathrm{eV} \tag{14.505}
\end{equation*}
$$

During hybridization, one of the spin-paired $2 s$ electrons is promoted to the $C 2 s p^{3}$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (14.145). Using Eqs. (14.145) and (14.505), the energy $E\left(C_{\text {ethane }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(C_{\text {ethane }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {ethane } 2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-15.55033 \mathrm{eV}+0.19086 \mathrm{eV}=-15.35946 \mathrm{eV} \tag{14.506}
\end{equation*}
$$

thus, $E_{T}\left(C-C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell with the formation of the $C-C$-bond MO is given by the difference between Eq. (14.146) and Eq. (14.506).

$$
\begin{equation*}
E_{T}\left(C-C, 2 s p^{3}\right)=E\left(C_{\text {ethane }}, 2 s p^{3}\right)-E\left(C, 2 s p^{3}\right)=-15.35946 \mathrm{eV}-(-14.63489 \mathrm{eV})=-0.72457 \mathrm{eV} \tag{14.507}
\end{equation*}
$$

Next, consider the formation of the $\mathrm{C}=\mathrm{C}$-bond MO of ethylene from two $\mathrm{CH}_{2}$ radicals, each having a $\mathrm{C} 2 s p^{3}$ electron with an energy given by Eq. (14.146). The sum $E_{T}\left(C_{\text {ehlylene }}, 2 s p^{3}\right)$ of calculated energies of $C 2 s p^{3}, C^{+}, C^{2+}$, and $C^{3+}$ is given by Eq. (14.147). The sharing of electrons between two pairs of $C 2 s p^{3}$ HOs to form a $C=C$-bond MO permits each participating HO to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each participating $C 2 s p^{3} \mathrm{HO}$ donates an excess of $25 \%$ of its electron density to the $C=C$-bond MO to form an energy minimum. By considering this electron redistribution in the ethylene molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{\text {ethylene } 2 s p^{3}}$ of the $C 2 s p^{3}$ shell of ethylene may be calculated from the Coulombic energy using Eqs. (10.102) and (14.147):

$$
\begin{align*}
r_{\text {ethylene } 2 s p^{3}} & =\left(\sum_{n=2}^{5}(Z-n)-0.5\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 151.61569 \mathrm{eV})} \\
& =\frac{9.5 e^{2}}{8 \pi \varepsilon_{0}(e 151.61569 \mathrm{eV})}  \tag{14.508}\\
& =0.85252 a_{0}
\end{align*}
$$

where $Z=6$ for carbon. Using Eqs. (10.102) and (14.508), the Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(C_{\text {ethylene }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {ethylene } 2 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.85252 a_{0}}=-15.95955 \mathrm{eV} \tag{14.509}
\end{equation*}
$$

During hybridization, one of the spin-paired $2 s$ electrons is promoted to the $C 2 s p^{3}$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (14.145). Using Eqs. (14.145) and (14.509), the energy $E\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(C_{\text {ethylene }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {ethylene } 2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-15.95955 \mathrm{eV}+0.19086 \mathrm{eV}=-15.76868 \mathrm{eV} \tag{14.510}
\end{equation*}
$$

thus, $E_{T}\left(C=C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell with the formation of the $C=C$-bond MO is given by the difference between Eq. (14.146) and Eq. (14.510):

$$
\begin{align*}
E_{T}\left(C=C, 2 s p^{3}\right) & =E\left(C_{\text {ethylene }}, 2 s p^{3}\right)-E\left(C, 2 s p^{3}\right) \\
& =-15.76868 \mathrm{eV}-(-14.63489 \mathrm{eV})  \tag{14.511}\\
& =-1.13380 \mathrm{eV}
\end{align*}
$$

To meet the energy matching condition for all $\sigma$ MOs at all $C 2 s p^{3} \mathrm{HOs}$, the energy $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell of each alkane carbon atom must be the average of $E\left(C_{\text {ethane }}, 2 s p^{3}\right)$ (Eq. (14.506)) and

$$
\begin{align*}
& E\left(C_{\text {ethylene }}, 2 s p^{3}\right) \text { (Eq. (14.510)). } \\
& E\left(C_{\text {alkane }}, 2 s p^{3}\right)=\frac{E\left(C_{\text {ethane }}, 2 s p^{3}\right)+E\left(C_{\text {ethylene }}, 2 s p^{3}\right)}{2} \\
& =\frac{(-15.35946 \mathrm{eV})+(-15.76868 \mathrm{eV})}{2}  \tag{14.512}\\
& =-15.56407 \mathrm{eV}
\end{align*}
$$

And, $E_{T_{\text {alkene }}}\left(C-C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell with the formation of each $C-C$-bond MO, must be the average of $E_{T}\left(C-C, 2 s p^{3}\right)$ (Eq. (14.507)) and $E_{T}\left(C=C, 2 s p^{3}\right)$ (Eq. (14.511)).

$$
\begin{align*}
E_{T_{\text {alkane }}}\left(C-C, 2 s p^{3}\right) & =\frac{E_{T}\left(C-C, 2 s p^{3}\right)+E_{T}\left(C=C, 2 s p^{3}\right)}{2} \\
& =\frac{(-0.72457 \mathrm{eV})+(-1.13379 \mathrm{eV})}{2}  \tag{14.513}\\
& =-0.92918 \mathrm{eV}
\end{align*}
$$

using Eq. (10.102), the radius $r_{\text {alkane2sp }}$ of the $C 2 s p^{3}$ shell of each carbon atom of $C_{n} H_{2 n+2}$ may be calculated from the Coulombic energy using the initial energy $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)=-14.82575 \mathrm{eV}$ (Eq. (14.143)) and $E_{T_{\text {alkene }}}\left(C-C, 2 s p^{3}\right)$ Eq. (14.513)), the energy change of each $C 2 s p^{3}$ shell with the formation of each $C-C$-bond MO. Consider the case of a methyl carbon which donates $E_{T_{\text {alkene }}}\left(C-C, 2 s p^{3}\right)$ Eq. (14.513)) to a single $C-C$ bond:

$$
\begin{align*}
r_{\text {alkane } 2 \text { sp }}{ }^{3} & =\frac{-e^{2}}{8 \pi \varepsilon_{0}\left(E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)+E_{T_{\text {alkane }}}\left(C-C, 2 s p^{3}\right)\right)} \\
& =\frac{e^{2}}{8 \pi \varepsilon_{0}(e 14.825751 e V+e 0.92918 \mathrm{eV})}  \tag{14.514}\\
& =0.86359 a_{0}
\end{align*}
$$

using Eqs. (10.102) and (14.514), the Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {alkane }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(C_{\text {alkane }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {alkanne2sp }}{ }^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.86359 a_{0}}=-15.75493 \mathrm{eV} \tag{14.515}
\end{equation*}
$$

During hybridization, one of the spin-paired $2 s$ electrons is promoted to the $C 2 s p^{3}$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (14.145). Using Eqs. (14.145) and (14.515), the energy $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell is:

$$
\begin{equation*}
E\left(C_{\text {alkane }}, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{\text {alkane } 2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-15.75493 \mathrm{eV}+0.19086 \mathrm{eV}=-15.56407 \mathrm{eV} \tag{14.516}
\end{equation*}
$$

thus, $E_{T_{\text {alkeme }}}\left(C-C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell with the formation of each $C-C$-bond MO is given by the difference between Eq. (14.146) and Eq. (14.516):

$$
\begin{equation*}
E_{T_{\text {alkane }}}\left(C-C, 2 s p^{3}\right)=E\left(C_{\text {alkane }}, 2 s p^{3}\right)-E\left(C, 2 s p^{3}\right)=-15.56407 \mathrm{eV}-(-14.63489 \mathrm{eV})=-0.92918 \mathrm{eV} \tag{14.517}
\end{equation*}
$$

which agrees with Eq. (14.513).
The energy contribution due to the charge donation at each carbon superimposes linearly. In general, the radius $r_{\text {mol } 2 s p^{3}}$ of the $C 2 s p^{3} \mathrm{HO}$ of a carbon atom of a group of a given molecule is calculated using Eq. (14.514) by considering $\sum E_{T_{\text {mol }}}\left(M O, 2 s p^{3}\right)$, the total energy donation to each bond with which it participates in bonding. The general equation for the radius is given by:

$$
\begin{align*}
r_{\text {mol } 2 s p^{3}} & =\frac{-e^{2}}{8 \pi \varepsilon_{0}\left(E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)+\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)\right)} \\
& =\frac{e^{2}}{8 \pi \varepsilon_{0}\left(e 14.825751 \mathrm{eV}+\sum\left|E_{T_{\text {mol }}}\left(M O, 2 s p^{3}\right)\right|\right)} \tag{14.518}
\end{align*}
$$

The $C 2 s p^{3} \mathrm{HO}$ of each methyl group of an alkane contributes -0.92918 eV to the corresponding single $C-C$ bond; thus, the corresponding $C 2 s p^{3}$ HO radius is given by Eq. (14.514). The $C 2 s p^{3} \mathrm{HO}$ of each methylene group of $C_{n} H_{2 n+2}$ contributes -0.92918 eV to each of the two corresponding $C-C$ bond MOs. Thus, the radius of each methylene group of an alkane is given by:

$$
\begin{align*}
r_{\text {alkane }_{\text {mecthlyenem }^{2 s p^{3}}}} & =\frac{-e^{2}}{8 \pi \varepsilon_{0}\left(E_{\text {Coulomb } \left.\left(C, 2 s p^{3}\right)+\sum E_{T_{\text {alkane }}}\left(\text { methylene } C-C, 2 s p^{3}\right)\right)}\right.} \begin{aligned}
& e^{2} \\
&=\frac{e_{0}(e 14.825751 \mathrm{eV}+e 0.92918 \mathrm{eV}+e 0.92918 \mathrm{eV})}{} \\
&=0.81549 a_{0}
\end{aligned}
\end{align*}
$$

As in the case with ethane, the $H_{2}$-type ellipsoidal MO comprises $75 \%$ of the $C-C$-bond MO shared between two $C 2 s p^{3}$ HOs corresponding to the electron charge density in Eq. (11.65) of $\frac{-0.75 e}{2}$. But, the additional $25 \%$ charge-density contribution to the $C-C$-bond MO causes the electron charge density in Eq. (11.65) to be $\frac{-e}{2}=-0.5 e$. Thus, the force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ in terms of the central force of the foci is given by Eq. (14.152). The distance from the origin of the $C-C$-bond MO to each focus $c^{\prime}$ is given by Eq. (14.153). The internuclear distance from is given by Eq. (14.154). The length of the semiminor axis of the prolate spheroidal $C-C$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of the $C-C$-bond MO. Since the $C-C$-bond MO comprises a $H_{2}$-type-ellipsoidal MO that transitions to the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ of each carbon, the energy $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$ in Eq. (14.512) adds to that of the $H_{2}$-type ellipsoidal MO to give the total energy of the $C-C$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the $C-C$-bond MO are solved. Similarly, $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$ is added to the energy of the $H_{2}$-type ellipsoidal MO of each $C-H$ bond of the methyl and methylene groups to give their total energy. From the energy equation and the relationship between the axes, the dimensions of the equivalent $C-H$-bond MOs of the methyl and methylene groups in the alkane are solved.

The general equations for the energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ of each $C-C$-bond MO are the same as those of the $C H$ MO except that energy of the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ is used. The energy components at each carbon atom superimpose linearly and may be treated independently. Since each prolate spheroidal $H_{2}$-type MO transitions to the $C_{\text {alkane }} 2 s p^{3}$ HO of each corresponding carbon of the bond and the energy of the $C_{\text {alkane }} 2 s p^{3}$ shell treated independently must remain constant and equal to the $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$ given by Eq. (14.512), the total energy $E_{T_{\text {alkane }}^{\prime}}^{\prime}(C-C, \sigma)$ of the $\sigma$ component of each $C-C$ bond MO is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ and the $H_{2}$-type ellipsoidal MO that forms the $\sigma$ component of the $C-C$-bond MO as given by Eq. (14.502) with the electron charge redistribution. The total number of $C-C$ bonds in $C_{n} H_{2 n+2}$ is $n-1$. Using Eqs. (13.431) and (14.512), $E_{T_{\text {alkane }}}(C-C, \sigma)$ of the $n-1$ bonds is given by:

$$
\begin{align*}
E_{T_{\text {alkane }}}(C-C, \sigma) & =(n-1)\left(E_{T}+E\left(C_{\text {alkane }}, 2 s p^{3}\right)\right) \\
& =(n-1)\left(-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.56407 \mathrm{eV}\right) \tag{14.520}
\end{align*}
$$

To match the boundary condition that the total energy of each $H_{2}$-type ellipsoidal MO is given by Eqs. (11.212) and (13.75), $E_{T_{a l a m e}}(C-C, \sigma)$ given by Eq. (14.520) is set equal to $(n-1)$ times Eq. (13.75).

$$
E_{T_{\text {allane }}}(C-C, \sigma)=(n-1)\left(\begin{array}{l}
\left.-\frac{e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]\right)=(n-1)(-31.63536831 \mathrm{eV})  \tag{14.521}\\
-15.56407 \mathrm{eV}
\end{array}\right.
$$

From the energy relationship given by Eq. (14.521) and the relationship between the axes given by Eqs. (14.153-14.154) and (13.62-13.63), the dimensions of the $C-C$-bond MO can be solved.

Substitution of Eq. (14.153) into Eq. (14.521) gives:

$$
\begin{equation*}
\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a a_{0}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{a a_{0}}}{a-\sqrt{a a_{0}}}-1\right]=e 16.07130 \tag{14.522}
\end{equation*}
$$

The most convenient way to solve Eq. (14.522) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is:

$$
\begin{equation*}
a=2.12499 a_{0}=1.12450 \times 10^{-10} \mathrm{~m} \tag{14.523}
\end{equation*}
$$

Substitution of Eq. (14.523) into Eq. (14.155) gives:

$$
\begin{equation*}
c^{\prime}=1.45774 a_{0}=7.71400 \times 10^{-11} \mathrm{~m} \tag{14.524}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.524) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.91547 a_{0}=1.54280 \times 10^{-10} \mathrm{~m} \tag{14.525}
\end{equation*}
$$

The experimental $C-C$ bond distance of propane is [3]:

$$
\begin{equation*}
2 c^{\prime}=1.532 \times 10^{-10} \mathrm{~m} \tag{14.526}
\end{equation*}
$$

The experimental $C-C$ bond distance of butane is [3]:

$$
\begin{equation*}
2 c^{\prime}=1.531 \times 10^{-10} \mathrm{~m} \tag{14.527}
\end{equation*}
$$

Substitution of Eqs. (14.523-14.524) into Eq. (13.62) gives:

$$
\begin{equation*}
b=c=1.54616 a_{0}=8.18192 \times 10^{-11} \mathrm{~m} \tag{14.528}
\end{equation*}
$$

Substitution of Eqs. (14.523-14.524) into Eq. (13.63) gives:

$$
\begin{equation*}
e=0.68600 \tag{14.529}
\end{equation*}
$$

The nucleus of the $C$ atoms comprise the foci of each $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where for methylene bonds $r_{n}=r_{\text {alkane2sp }}=r_{\text {methylenessp }}=0.81549 a_{0}$ is the radius of the $C_{\text {alkane }} 2 s p^{3}$ shell given by Eq. (14.519). Substitution of Eqs. (14.523-14.524) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=56.41^{\circ} \tag{14.530}
\end{equation*}
$$

Then, the angle $\theta_{C-C_{\text {alame }} 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C-C_{\text {alkane }} 2 s p^{3} H O}=180^{\circ}-56.41^{\circ}=123.59^{\circ} \tag{14.531}
\end{equation*}
$$

as shown in Figure 14.16.
Figure 14.16. The cross section of one $C-C$-bond $\mathrm{MO}(\sigma \mathrm{MO})$ and one $C-H$-bond MO of $C_{n} H_{2 n+2}$ showing the axes, angles, and point of intersection of each $H_{2}$-type ellipsoidal MO with the corresponding $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$. The continuation of each $H_{2}$-type-ellipsoidal-MO basis element of the $C-C$ bond and the $C-H$-bond beyond the intersection point with each $C_{\text {alkane }} 2 s p^{3}$ shell and $\sigma$ MO is shown as dashed since each only serves to solve the energy match with the $C_{\text {alkane }} 2 s p^{3}$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of each intersection point. The actual charge density is shown by the solid lines. Legend: $a$ : semimajor axis, $b$ : semiminor axis, $c^{\prime}$ : internuclear distance, $d_{1}: d_{C-C_{\text {alkane }}, H_{2} M O}, \theta_{1}: \theta_{C-C_{\text {alame }} 2 s p^{3} H O}, d_{2}: d_{C-C_{\text {alanere }} 2 s p^{3} H O}, R: r_{\text {alkane } C 2 s p^{3}}, d_{3}: d_{C-H_{\text {alkane }}, H_{2} M O}, \theta_{2}: \theta_{C-H_{\text {alkane }} 2 s p^{3} H O}$, and $d_{4}: d_{C-H_{\text {alkane }} 2 s p^{3} H O}$.

Consider the right-hand intersection point. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$ coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{C-C_{\text {alame }}, H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{\text {alkane } 2 s p^{3}} \sin \theta_{C-C_{\text {alkane }} 2 s p^{3} H O}=0.81549 a_{0} \sin \theta_{C-C_{\text {alkane }} 2 s p^{3} H O}=b \sin \theta_{C-C_{\text {alkane }}, H_{2} M O} \tag{14.532}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{C-C_{\text {alkane } e}, H_{2} M O}=\sin ^{-1} \frac{0.81549 a_{0} \sin \theta_{C-C_{\text {alkane }} 2 s p^{3} H O}}{b}=\sin ^{-1} \frac{0.81549 a_{0} \sin 123.59^{\circ}}{b} \tag{14.533}
\end{equation*}
$$

with the use of Eq. (14.531). Substitution of Eq. (14.528) into Eq. (14.533) gives:

$$
\begin{equation*}
\theta_{C-C_{\text {alkmene }}, H_{2} M O}=26.06^{\circ} \tag{14.534}
\end{equation*}
$$

Then, the distance $d_{C-C_{\text {alame }}, H_{2} M O}$ along the internuclear axis from the origin of $H_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by

$$
\begin{equation*}
d_{C-C_{\text {alkance }}, H_{2} M O}=a \cos \theta_{C-C_{\text {alkane }}, H_{2} M O} \tag{14.535}
\end{equation*}
$$

Substitution of Eqs. (14.523) and (14.534) into Eq. (14.535) gives:

$$
\begin{equation*}
d_{C-C_{\text {alkme }}, H_{2} M O}=1.90890 a_{0}=1.01015 \times 10^{-10} \mathrm{~m} \tag{14.536}
\end{equation*}
$$

The distance $d_{C-C_{\text {alkane }} 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C-C_{\text {alkane }} 2 p^{3} H O}=d_{C-C_{\text {akane } e}, H_{2} M O}-c^{\prime} \tag{14.537}
\end{equation*}
$$

Substitution of Eqs. (14.524) and (14.536) into Eq. (14.537) gives:

$$
\begin{equation*}
d_{C-C_{\text {alkene }} 2 s p^{3} H O}=0.45117 a_{0}=2.38748 \times 10^{-11} \mathrm{~m} \tag{14.538}
\end{equation*}
$$

## FORCE BALANCE OF THE $\mathrm{CH}_{3}$ MOs OF CONTINUOUS-CHAIN ALKANES

Each of the two $\mathrm{CH}_{3}$ MOs must comprise three equivalent $\mathrm{C}-\mathrm{H}$ bonds with each comprising $75 \%$ of a $H_{2}$-type ellipsoidal MO and a $C 2 s p^{3} \mathrm{HO}$ as given by Eq. (13.540).

$$
\begin{equation*}
3\left[1 \mathrm{C} 2 \mathrm{sp}^{3}+0.75 \mathrm{H}_{2} \mathrm{MO}\right] \rightarrow \mathrm{CH}_{3} \mathrm{MO} \tag{14.539}
\end{equation*}
$$

The force balance of the $\mathrm{CH}_{3} \mathrm{MO}$ is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.539) and the energy matching condition between the hydrogen and $C 2 s p^{3} \mathrm{HO}$ components of the MO.

The force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ of the each $H_{2}$-type-ellipsoidal-MO component of the $\mathrm{CH}_{3} \mathrm{MO}$ in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $\mathrm{C}-\mathrm{H}$-bond MO to each focus $c^{\prime}$ is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $\mathrm{C}-\mathrm{H}-$ bond MO. Since each of the three prolate spheroidal $\mathrm{C}-\mathrm{H}$-bond MOs comprises an $H_{2}$-type-ellipsoidal MO that transitions to the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ of $C_{n} H_{2 n+2}$, the energy $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$ of Eq. (14.512) adds to that of the three corresponding $H_{2}$-type ellipsoidal MOs to give the total energy of the $\mathrm{CH}_{3} \mathrm{MO}$. From the energy equation and the relationship between the axes, the dimensions of the $\mathrm{CH}_{3} \mathrm{MO}$ are solved.

The energy components of $V_{e}, V_{p}, T$, and $V_{m}$ are the same as those of methyl radical, three times those of CH corresponding to the three $C-H$ bonds except that energy of the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ is used. Since each prolate spheroidal $\mathrm{H}_{2}-$ type MO transitions to the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ and the energy of the $C_{\text {alkane }} 2 s p^{3}$ shell must remain constant and equal to the $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$ given by Eq. (14.512), the total energy $E_{T_{\text {alkane }}}\left(\mathrm{CH}_{3}\right)$ of the $\mathrm{CH}_{3} \mathrm{MO}$ is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ and the three $H_{2}$-type ellipsoidal MOs that forms the $\mathrm{CH}_{3} \mathrm{MO}$ as given by Eq. (14.539). Using Eq. (13.431) or Eq. (13.541), $E_{T_{\text {alkane }}}\left(\mathrm{CH}_{3}\right)$ is given by:

$$
\begin{equation*}
E_{T_{\text {alkane }}}\left(\mathrm{CH}_{3}\right)=E_{T}+E\left(C_{\text {alkane }}, 2 s p^{3}\right)=-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.56407 \mathrm{eV} \tag{14.540}
\end{equation*}
$$

$E_{T_{\text {alane }}}\left(\mathrm{CH}_{3}\right)$ given by Eq. (14.540) is set equal to three times the energy of the $H_{2}$-type ellipsoidal MO minus two times the Coulombic energy of $H$ given by Eq. (13.542):

$$
\begin{equation*}
E_{T}\left(\mathrm{CH}_{3}\right)=-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.56407 \mathrm{eV}=-67.69450 \mathrm{eV} \tag{14.541}
\end{equation*}
$$

From the energy relationship given by Eq. (14.541) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the $\mathrm{CH}_{3}$ MO can be solved.

Substitution of Eq. (13.60) into Eq. (14.541) gives:

$$
\begin{equation*}
\frac{3 e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right]=e 52.13044 \tag{14.542}
\end{equation*}
$$

The most convenient way to solve Eq. (14.542) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is:

$$
\begin{equation*}
a=1.64920 a_{0}=8.72720 \times 10^{-11} \mathrm{~m} \tag{14.543}
\end{equation*}
$$

Substitution of Eq. (14.543) into Eq. (14.60) gives:

$$
\begin{equation*}
c^{\prime}=1.04856 a_{0}=5.54872 \times 10^{-11} \mathrm{~m} \tag{14.544}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.544) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.09711 a_{0}=1.10974 \times 10^{-10} \mathrm{~m} \tag{14.545}
\end{equation*}
$$

The experimental $C-H$ bond distance of propane is [3]:

$$
\begin{equation*}
2 c^{\prime}=1.107 \times 10^{-10} \mathrm{~m} \tag{14.546}
\end{equation*}
$$

Substitution of Eqs. (14.543-14.544) into Eq. (14.62) gives:

$$
\begin{equation*}
b=c=1.27295 a_{0}=6.73616 \times 10^{-11} \mathrm{~m} \tag{14.547}
\end{equation*}
$$

Substitution of Eqs. (14.543-14.544) into Eq. (14.63) gives:

$$
\begin{equation*}
e=0.63580 \tag{14.548}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $C$ atom comprise the foci of each $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{\text {alkane } 2 s p^{3}}=0.86359 a_{0}$ is the radius of the $C_{\text {alkane }} 2 s p^{3}$ shell. Substitution of Eqs. (14.543-14.544) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=77.49^{\circ} \tag{14.549}
\end{equation*}
$$

Then, the angle $\theta_{C-H_{\text {alkane }} 2 s p^{3} H O}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C-H_{\text {alkane }} 2 s p^{3} H O}=180^{\circ}-77.49^{\circ}=102.51^{\circ} \tag{14.550}
\end{equation*}
$$

as shown in Figure 14.17.
Figure 14.17. The cross section of one $C-H$-bond MO of $C_{n} H_{2 n+2}$ showing the axes, angles, and point of intersection of the $H_{2}$-type ellipsoidal MO with the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$. The continuation of the $H_{2}$-type-ellipsoidal-MO basis element beyond the intersection point with the $C_{\text {alkane }} 2 s p^{3}$ shell is shown as dashed since it only serves to solve the energy match with the $C_{\text {alkane }} 2 s p^{3}$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of the intersection point. The actual charge density is shown by the solid lines. Legend: $a$ : semimajor axis, $b:$ semiminor axis, $c^{\prime}$ : internuclear distance, $d_{1}: d_{C-H_{\text {alkane }}, H_{2} M O}, \theta_{1}: \theta_{C-H_{\text {alkane }} 2 s p^{3} H O}, d_{2}: d_{C-H_{\text {alkane }} 2 s p^{3} H O}$, and $R: r_{\text {alkane } 2 s p^{3}}$.

The Cartesian i-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{C-H_{\text {alkane }}, H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{\text {alkane2sp3}^{3}} \sin \theta_{C-H_{\text {alkane }} 2 s p^{3} H O}=0.86359 a_{0} \sin \theta_{C-H_{\text {alkane }} 2 s p^{3} H O}=b \sin \theta_{C-H_{\text {alkane }}, H_{2} M O} \tag{14.551}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{C-H_{\text {alkane }}, H_{2} M O}=\sin ^{-1} \frac{0.86359 a_{0} \sin \theta_{C-H_{\text {alkane }} 2 s p^{3} H O}}{b}=\sin ^{-1} \frac{0.86359 a_{0} \sin 102.51^{\circ}}{b} \tag{14.552}
\end{equation*}
$$

with the use of Eq. (14.550). Substitution of Eq. (14.547) into Eq. (14.552) gives:

$$
\begin{equation*}
\theta_{C-H_{\text {alkane }}, H_{2} M O}=41.48^{\circ} \tag{14.553}
\end{equation*}
$$

Then, the distance $d_{C-H_{\text {alkane }}, H_{2} M O}$ along the internuclear axis from the origin of $H_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C-H_{\text {alkane }}, H_{2} M O}=a \cos \theta_{C-H_{\text {alkane } e}, H_{2} M O} \tag{14.554}
\end{equation*}
$$

Substitution of Eqs. (14.543) and (14.553) into Eq. (14.554) gives:

$$
\begin{equation*}
d_{C-H_{\text {alkane }}, H_{2} M O}=1.23564 a_{0}=6.53871 \times 10^{-11} \mathrm{~m} \tag{14.555}
\end{equation*}
$$

The distance $d_{C-H_{\text {alkane }} 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by

$$
\begin{equation*}
d_{C-\mathrm{H}_{\text {alkane }} 2 \mathrm{sp}{ }^{3} \mathrm{HO}}=d_{C-\mathrm{H}_{\text {alkane }}, \mathrm{H}_{2} \mathrm{MO}}-c^{\prime} \tag{14.556}
\end{equation*}
$$

Substitution of Eqs. (14.544) and (14.555) into Eq. (14.556) gives:

$$
\begin{equation*}
d_{C-H_{\text {alkane }} 2 s p^{3} H O}=0.18708 a_{0}=9.89999 \times 10^{-12} \mathrm{~m} \tag{14.557}
\end{equation*}
$$

## BOND ANGLE OF THE $\mathrm{CH}_{3}$ AND $\mathrm{CH}_{2}$ GROUPS

Each $\mathrm{CH}_{3} \mathrm{MO}$ comprises a linear combination of three $\mathrm{C}-\mathrm{H}$-bond MOs. Each $\mathrm{C}-\mathrm{H}$-bond MO comprises the superposition of a $H_{2}$-type ellipsoidal MO and the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$. A bond is also possible between the two H atoms of the $C-H$ bonds. Such $H-H$ bonding would decrease the $C-H$ bond strength since electron density would be shifted from the $C-H$ bonds to the $H-H$ bond. Thus, the bond angle between the two $C-H$ bonds is determined by the condition that the total energy of the $H_{2}$-type ellipsoidal MO between the terminal $H$ atoms of the $C-H$ bonds is zero. From Eqs. (11.79) and (13.228), the distance from the origin to each focus of the $H-H$ ellipsoidal MO is:

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 2 a}}=\sqrt{\frac{a a_{0}}{2}} \tag{14.558}
\end{equation*}
$$

The internuclear distance from Eq. (14.558) is:

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{\frac{a a_{0}}{2}} \tag{14.559}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal $H-H$ MO $b=c$ is given by Eq. (14.62).
The bond angle of the $\mathrm{CH}_{3}$ groups of $\mathrm{C}_{n} \mathrm{H}_{2 n+2}$ is derived by using the orbital composition and an energy matching factor as in the case with the $\mathrm{CH}_{3}$ radical. Since each pair of $\mathrm{H}_{2}$-type ellipsoidal MOs initially comprise $75 \%$ of the $H$ electron density of $\mathrm{H}_{2}$ and the energy of each $H_{2}$-type ellipsoidal MO is matched to that of the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$, the component energies and the total energy $E_{T}$ of the $H-H$ bond are given by Eqs. (13.67-13.73) except that $V_{e}, T$, and $V_{m}$ are corrected for the hybridization-energy-matching factor of 0.86359 . Hybridization with $25 \%$ electron donation to the $C-C$-bond gives rise to the $C_{\text {alkane }} 2 s p^{3}$ HO-shell Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {alkane }}, 2 s p^{3}\right)$ given by Eq. (14.515). The corresponding normalization factor for determining the zero of the total $H-H$ bond energy is given by the ratio of 15.75493 eV , the magnitude of $E_{\text {Coulomb }}\left(C_{\text {alkane }}, 2 s p^{3}\right)$ given by Eq. (14.515), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). The hybridization energy factor $C_{\text {alkaneC2sp }{ }^{3} H O}$ is:

$$
\begin{equation*}
C_{\text {alkaneC } 2 s p^{3} H O}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} r_{\text {alkane } 2 \text { sp }}{ }^{3}}}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} 0.86359 a_{0}}}=\frac{13.605804 \mathrm{eV}}{15.75493 \mathrm{eV}}=0.86359 \tag{14.560}
\end{equation*}
$$

Substitution of Eq. (14.558) into Eq. (13.233) with the hybridization factor of 0.86359 gives:

$$
0=\left[\begin{array}{l}
\frac{-e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2}}}\left[(0.86359)^{-1}\left(\frac{3}{2}-\frac{3}{8} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2}}}{a-\sqrt{\frac{a a_{0}}{2}}}-1\right]\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}}{m_{e} c^{2}}}\right]  \tag{14.561}\\
+\hbar \sqrt{\frac{\frac{0.75 e^{2}}{8 \pi \varepsilon_{0} a^{3}}-\frac{e^{2}}{8 \pi \varepsilon_{0}\left(a+c^{\prime}\right)^{3}}}{0.5 m_{p}}}
\end{array}\right]
$$

From the energy relationship given by Eq. (14.561) and the relationship between the axes given by Eqs. (14.558-14.559) and (14.62-14.63), the dimensions of the $H-H$ MO can be solved.

The most convenient way to solve Eq. (14.561) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$
\begin{equation*}
a=5.8660 a_{0}=3.1042 \times 10^{-10} \mathrm{~m} \tag{14.562}
\end{equation*}
$$

Substitution of Eq. (14.562) into Eq. (14.558) gives:

$$
\begin{equation*}
c^{\prime}=1.7126 a_{0}=9.0627 \times 10^{-11} \mathrm{~m} \tag{14.563}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.563) by two is:

$$
\begin{equation*}
2 c^{\prime}=3.4252 a_{0}=1.8125 \times 10^{-10} \mathrm{~m} \tag{14.564}
\end{equation*}
$$

Substitution of Eqs. (14.562-14.563) into Eq. (14.62) gives:

$$
\begin{equation*}
b=c=5.6104 a_{0}=2.9689 \times 10^{-10} \mathrm{~m} \tag{14.565}
\end{equation*}
$$

Substitution of Eqs. (14.562-14.563) into Eq. (14.63) gives:

$$
\begin{equation*}
e=0.2920 \tag{14.566}
\end{equation*}
$$

Using $2{c^{\prime}}_{H-H}$ (Eq. (14.564)), the distance between the two $H$ atoms when the total energy of the corresponding MO is zero (Eq. (14.561)), and $2 c_{C-H}^{\prime}$, the internuclear distance of each $C-H$ bond, the corresponding bond angle can be determined from the law of cosines. Since the internuclear distance of each $\mathrm{C}-\mathrm{H}$ bond of $\mathrm{CH}_{3}$ (Eq. (14.545)) and $\mathrm{CH}_{2}$ (Eq. (14.597)) are sufficiently equivalent, the bond angle determined with either is within experimental error of being the same. Using, Eqs. (13.242), (14.545), and (14.564), the bond angle $\theta$ between the $C-H$ bonds is:

$$
\begin{equation*}
\theta=\cos ^{-1}\left(\frac{2(2.09711)^{2}-(3.4252)^{2}}{2(2.09711)^{2}}\right)=\cos ^{-1}(-0.33383)=109.50^{\circ} \tag{14.567}
\end{equation*}
$$

The experimental angle between the $C-H$ bonds is [19]:

$$
\begin{equation*}
\theta=109.3^{\circ} \tag{14.568}
\end{equation*}
$$

The $\mathrm{CH}_{3}$ radical has a pyramidal structure with the carbon atom along the z-axis at the apex and the hydrogen atoms at the base in the xy-plane. The distance $d_{\text {origin-H }}$ from the origin to the nucleus of a hydrogen atom given by Eqs. (14.564) and (13.412) is:

$$
\begin{equation*}
d_{\text {origin }-H}=1.97754 a_{0} \tag{14.569}
\end{equation*}
$$

The height along the z-axis of the pyramid from the origin to $C$ nucleus $d_{\text {height }}$ given by Eqs. (13.414), (14.545), and (14.569) is

$$
\begin{equation*}
d_{\text {height }}=0.69800 a_{0} \tag{14.570}
\end{equation*}
$$

The angle $\theta_{v}$ of each $C-H$ bond from the z-axis given by Eqs. (13.416), (14.569), and (14.570) is:

$$
\begin{equation*}
\theta_{v}=70.56^{\circ} \tag{14.571}
\end{equation*}
$$

The $C-C$ bond is along the z-axis. Thus, the bond angle $\theta_{C-C-H}$ between the internuclear axis of the $C-C$ bond and a $H$ atom of the methyl groups is given by:

$$
\begin{equation*}
\theta_{C-C-H}=180-\theta_{v} \tag{14.572}
\end{equation*}
$$

Substitution of Eq. (14.571) into Eq. (14.572) gives:

$$
\begin{equation*}
\theta_{C-C-H}=109.44^{\circ} \tag{14.573}
\end{equation*}
$$

The experimental angle between the $\mathrm{C}-\mathrm{C}-\mathrm{H}$ bonds is [19]:

$$
\begin{equation*}
\theta_{C-C-H}=109.3^{\circ} \tag{14.574}
\end{equation*}
$$

The $C_{n} H_{2 n+2}$ MOs shown in Figures 14.18-14.28 were rendered using these parameters. A minimum energy is obtained with a staggered configuration consistent with observations [3].

## ENERGIES OF THE $\mathrm{CH}_{3}$ GROUPS

The energies of each $\mathrm{CH}_{3}$ group of $C_{n} H_{2 n+2}$ are given by the substitution of the semiprincipal axes (Eqs. (14.543-14.544) and (14.547)) into the energy equations of methyl radical (Eqs. (13.556-13.560)), with the exception that $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$ (Eq. (14.514)) replaces $E\left(C, 2 s p^{3}\right)$ in Eq. (13.560).

$$
\begin{align*}
& V_{e}=3(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-107.32728 \mathrm{eV}  \tag{14.575}\\
& V_{p}=\frac{3 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=38.92728 \mathrm{eV}  \tag{14.576}\\
& T=3(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=32.53914 \mathrm{eV}  \tag{14.577}\\
& V_{m}=3(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-16.26957 \mathrm{eV}  \tag{14.578}\\
& E_{T_{\text {alkane }}}\left(C H_{3}\right)=\left(\begin{array}{l}
\left.-\frac{3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]\right)=-67.69451 \mathrm{eV} \\
-15.56407 \mathrm{eV}
\end{array}\right. \tag{14.579}
\end{align*}
$$

where $E_{T_{\text {alkewe }}}\left(\mathrm{CH}_{3}\right)$ is given by Eq. (14.540) which is reiteratively matched to Eq. (13.542) within five-significant-figure round off error.

## VIBRATION OF THE ${ }^{12} \mathrm{CH}_{3}$ GROUPS

The vibrational energy levels of the $\mathrm{C}-\mathrm{H}$ bonds of $\mathrm{CH}_{3}$ in $\mathrm{C}_{n} H_{2 n+2}$ may be solved as three equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERMS OF THE ${ }^{12} \mathrm{CH}_{3}$ GROUPS

The equations of the radiation reaction force of the methyl groups in $C_{n} H_{2 n+2}$ are the same as those of the methyl radical with the substitution of the methyl-group parameters. Using Eq. (13.561), the angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=2.49286 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{14.580}
\end{equation*}
$$

where $b$ is given by Eq. (14.547). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 2.49286 \times 10^{16} \mathrm{rad} / \mathrm{s}=16.40846 \mathrm{eV} \tag{14.581}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each $H_{2}$-type MO, for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.581) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-31.63537 \mathrm{eV} \sqrt{\frac{2 e(16.40846 \mathrm{eV})}{m_{e} c^{2}}}=-0.25352 \mathrm{eV} \tag{14.582}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of $\mathrm{CH}_{3}$ due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.582) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of each $C-H$ bond. Using $\omega_{e}$ given by Eq. (13.458) for $\bar{E}_{\text {Kvib }}$ of the transition state having three independent bonds, $\left.\bar{E}_{\text {alkane osc }}{ }^{12}{ }^{12} \mathrm{CH}_{3}\right)$ per bond is:

$$
\begin{align*}
& \bar{E}_{\text {alkane osc }}^{\prime}\left({ }^{12} \mathrm{CH}_{3}\right)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{14.583}\\
& \bar{E}_{\text {alkane osc }}^{\prime}\left({ }^{12} \mathrm{CH}_{3}\right)=-0.25352 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})=-0.07586 \mathrm{eV} \tag{14.584}
\end{align*}
$$

Given that the vibration and reentrant oscillation is for three $\mathrm{C}-\mathrm{H}$ bonds, $\bar{E}_{\text {alkane osc }}\left({ }^{12} \mathrm{CH}_{3}\right)$, is:

$$
\begin{equation*}
\bar{E}_{\text {alkane osc }}\left({ }^{12} \mathrm{CH}_{3}\right)=3\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)=3\left(-0.25352 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})\right)=-0.22757 \mathrm{eV} \tag{14.585}
\end{equation*}
$$

## TOTAL BOND ENERGIES OF THE ${ }^{12} \mathrm{CH}_{3}$ GROUPS

$E_{\text {alkaneT +osc }}\left({ }^{12} \mathrm{CH}_{3}\right)$, the total energy of each ${ }^{12} \mathrm{CH}_{3}$ group including the Doppler term, is given by the sum of $E_{T_{\text {alkane }}}\left(\mathrm{CH}_{3}\right)$ (Eq. (14.579)) and $\bar{E}_{\text {alkane osc }}\left({ }^{12} \mathrm{CH}_{3}\right)$ given by Eq. (14.585).

$$
\begin{align*}
E_{\text {alkaneT Tosc }}\left({ }^{12} \mathrm{CH}_{3}\right) & =V_{e}+T+V_{m}+V_{p}+E\left(C_{\text {alkane }}, 2 s p^{3}\right)+\bar{E}_{\text {alkane osc }}\left({ }^{12} \mathrm{CH}_{3}\right)=E_{T_{\text {akkene }}}\left(\mathrm{CH}_{3}\right)+\bar{E}_{\text {alkane osc }}\left({ }^{12} \mathrm{CH}_{3}\right)  \tag{14.586}\\
E_{\text {alkaneT }+ \text { osc }}\left({ }^{12} \mathrm{CH}_{3}\right) & =\left\{\begin{array}{l}
\left(\frac{-3 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.56407 \mathrm{eV}\right) \\
\left.-3(31.63536831 \mathrm{eV}) \sqrt{\frac{\sqrt{\frac{3}{\frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}}}{m_{e}}}-\frac{1}{m_{e} c^{2}} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{array}\right\}  \tag{14.587}\\
& =-67.69450 \mathrm{eV}-3\left(0.25352 \mathrm{eV}-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{align*}
$$

From Eqs. (14.585-14.587), the total energy of each ${ }^{12} \mathrm{CH}_{3}$ is:

$$
\begin{align*}
E_{\text {alkaneT Tosc }}\left({ }^{12} \mathrm{CH}_{3}\right) & =-67.69450 \mathrm{eV}+\bar{E}_{\text {alkane osc }}\left({ }^{12} \mathrm{CH}_{3}\right) \\
& =-67.69450 \mathrm{eV}-3\left(0.25352 \mathrm{eV}-\frac{1}{2}(0.35532 \mathrm{eV})\right)=-67.92207 \mathrm{eV} \tag{14.588}
\end{align*}
$$

where $\omega_{e}$ given by Eq. (13.458) was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The total $\mathrm{CH}_{3}$ bond dissociation energy, $E_{D_{\text {alkene }}}\left({ }^{12} \mathrm{CH}_{3}\right)$ is given by the sum of the initial $\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO}$ energy, $E\left(\mathrm{C}, 2 s p^{3}\right)$ (Eq. (14.146)), and three times the energy of the hydrogen atom, $E_{D}(H)$ (Eq. (13.154)), minus $E_{\text {alkaneT }+ \text { osc }}\left({ }^{12} \mathrm{CH}_{3}\right)$ (Eq. (14.588)).

$$
\begin{equation*}
E_{D_{\text {alkare }}}\left({ }^{12} \mathrm{CH}_{3}\right)=E\left(\mathrm{C}, 2 s p^{3}\right)+3 E(H)-E_{\text {alkaneT Tosc }}\left({ }^{12} \mathrm{CH}_{3}\right) \tag{14.589}
\end{equation*}
$$

Thus, the total ${ }^{12} \mathrm{CH}_{3}$ bond dissociation energy, $E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{3}\right)$ is:

$$
\begin{align*}
E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{3}\right) & =-(14.63489 \mathrm{eV}+3(13.59844 \mathrm{eV}))-\left(E_{\text {alkane T+asc }}\left({ }^{12} \mathrm{CH}_{2}\right)\right)  \tag{14.590}\\
& =-55.43021 \mathrm{eV}-(-67.92207 \mathrm{eV})=12.49186 \mathrm{eV}
\end{align*}
$$

## FORCE BALANCE OF THE $\mathrm{CH}_{2}$ MOs OF CONTINUOUS-CHAIN ALKANES

Each of the $\mathrm{CH}_{2}$ MOs must comprise two equivalent $\mathrm{C}-\mathrm{H}$ bonds with each comprising $75 \%$ of a $\mathrm{H}_{2}$-type ellipsoidal MO and a $C 2 s p^{3} \mathrm{HO}$ as given by Eq. (13.494).

$$
\begin{equation*}
2\left[1 \mathrm{C}_{2} s p^{3}+0.75 \mathrm{H}_{2} \mathrm{MO}\right] \rightarrow \mathrm{CH}_{2} \mathrm{MO} \tag{14.591}
\end{equation*}
$$

The force balance of each $\mathrm{CH}_{2} \mathrm{MO}$ is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.591) and the energy matching condition between the hydrogen and $C 2 s p^{3} \mathrm{HO}$ components of the MO.
The force constant $k^{\prime}$ to determine the ellipsoidal parameter $c^{\prime}$ of the each $\mathrm{H}_{2}$-type-ellipsoidal-MO component of the $\mathrm{CH}_{2} \mathrm{MO}$ in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus $c^{\prime}$ is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, $e$, is given by Eq. (13.63). The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $C-H$-bond MO. Since each of the two prolate spheroidal $C-H$-bond MOs comprises an $H_{2}$-type-ellipsoidal MO that transitions to the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ of $C_{n} H_{2 n+2}$, the energy $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$ of Eq. (14.512) adds to that of the two corresponding $H_{2}$-type ellipsoidal

MOs to give the total energy of the $\mathrm{CH}_{2} \mathrm{MO}$. From the energy equation and the relationship between the axes, the dimensions of the $\mathrm{CH}_{2} \mathrm{MO}$ are solved.

The energy components of $V_{e}, V_{p}, T$, and $V_{m}$ are the same as those of dihydrogen carbide radical, two times those of CH corresponding to the two $\mathrm{C}-\mathrm{H}$ bonds except that energy of the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ is used. Since each prolate spheroidal $\mathrm{H}_{2}$ type MO transitions to the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ and the energy of the $C_{\text {alkane }} 2 s p^{3}$ shell treated independently must remain constant and equal to the $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$ given by Eq. (14.512), the total energy $E_{T_{\text {alkane }}}\left(\mathrm{CH}_{2}\right)$ of the $\mathrm{CH}_{2} \mathrm{MO}$ is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ and the two $H_{2}$-type ellipsoidal MOs that forms the $\mathrm{CH}_{2} \mathrm{MO}$ as given by Eq. (14.591). Using Eq. (13.431) or Eq. (13.495), $E_{T_{\text {alkane }}}\left(\mathrm{CH}_{2}\right)$ is given by:

$$
\begin{equation*}
E_{T_{\text {alakee }}}\left(\mathrm{CH}_{2}\right)=E_{T}+E\left(C_{\text {alkane }}, 2 s p^{3}\right)=-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.56407 \mathrm{eV} \tag{14.592}
\end{equation*}
$$

$E_{T_{\text {alkane }}}\left(\mathrm{CH}_{2}\right)$ given by Eq. (14.592) is set equal to two times the energy of the $H_{2}$-type ellipsoidal MO minus the Coulombic energy of $H$ given by Eq. (13.496).

$$
\begin{equation*}
E_{T}\left(C H_{2}\right)=-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.56407 \mathrm{eV}=-49.66493 \mathrm{eV} \tag{14.593}
\end{equation*}
$$

From the energy relationship given by Eq. (14.593) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the $\mathrm{CH}_{2} \mathrm{MO}$ can be solved.

Substitution of Eq. (13.60) into Eq. (14.593) gives:

$$
\begin{equation*}
\frac{2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{2 a a_{0}}{3}}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{2 a a_{0}}{3}}}{a-\sqrt{\frac{2 a a_{0}}{3}}}-1\right]=e 34.10086 \tag{14.594}
\end{equation*}
$$

The most convenient way to solve Eq. (14.594) is by the reiterative technique using a computer. The result to within the roundoff error with five-significant figures is

$$
\begin{equation*}
a=1.67122 a_{0}=8.84370 \times 10^{-11} \mathrm{~m} \tag{14.595}
\end{equation*}
$$

Substitution of Eq. (14.595) into Eq. (14.60) gives:

$$
\begin{equation*}
c^{\prime}=1.05553 a_{0}=5.58563 \times 10^{-11} \mathrm{~m} \tag{14.596}
\end{equation*}
$$

The internuclear distance given by multiplying Eq. (14.596) by two is:

$$
\begin{equation*}
2 c^{\prime}=2.11106 a_{0}=1.11713 \times 10^{-10} \mathrm{~m} \tag{14.597}
\end{equation*}
$$

The experimental $C-H$ bond distance of butane is [3]:

$$
\begin{equation*}
2 c^{\prime}=1.117 \times 10^{-10} \mathrm{~m} \tag{14.598}
\end{equation*}
$$

Substitution of Eqs. (14.595-14.596) into Eq. (14.62) gives:

$$
\begin{equation*}
b=c=1.29569 a_{0}=6.85652 \times 10^{-11} \mathrm{~m} \tag{14.599}
\end{equation*}
$$

Substitution of Eqs. (14.595-14.596) into Eq. (14.63) gives:

$$
\begin{equation*}
e=0.63159 \tag{14.600}
\end{equation*}
$$

The nucleus of the $H$ atom and the nucleus of the $C$ atom comprise the foci of each $H_{2}$-type ellipsoidal MO. The parameters of the point of intersection of the $H_{2}$-type ellipsoidal MO and the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle $\theta^{\prime}$ is given by Eq. (13.261) where $r_{n}=r_{\text {methylenessp }}=0.81549 a_{0}$ is the radius of the $C_{\text {methylene }} 2 s p^{3}$ shell (Eq. (14.521)). Substitution of Eqs. (14.595-14.596) into Eq. (13.261) gives:

$$
\begin{equation*}
\theta^{\prime}=68.47^{\circ} \tag{14.601}
\end{equation*}
$$

Then, the angle $\theta_{C-H_{\text {alkane } 2 s p^{3} H O}}$ the radial vector of the $C 2 s p^{3} \mathrm{HO}$ makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{C-H_{\text {alkane }} 2 s p^{3} H O}=180^{\circ}-68.47^{\circ}=111.53^{\circ} \tag{14.602}
\end{equation*}
$$

as shown in Figure 14.17. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{C-H_{\text {alkane }}, H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{\text {alkane } 2 s p^{3}} \sin \theta_{C-H_{\text {alkane }^{2 s p}}{ }^{3} H O}=0.81549 a_{0} \sin \theta_{C-H_{\text {alkane }} 2 s p^{3} H O}=b \sin \theta_{C-H_{\text {alkane }}, H_{2} M O} \tag{14.603}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{C-H_{\text {alkane }}, H_{2} M O}=\sin ^{-1} \frac{0.81549 a_{0} \sin \theta_{C-H_{\text {alkane }} 2 s p^{3} H O}}{b}=\sin ^{-1} \frac{0.81549 a_{0} \sin 111.53^{\circ}}{b} \tag{14.604}
\end{equation*}
$$

with the use of Eq. (14.602). Substitution of Eq. (14.599) into Eq. (14.604) gives:

$$
\begin{equation*}
\theta_{C-H_{\text {alkane }}, H_{2} M O}=35.84^{\circ} \tag{14.605}
\end{equation*}
$$

Then, the distance $d_{C-H_{\text {alkane }}, \mathrm{H}_{2} \mathrm{MO}}$ along the internuclear axis from the origin of $H_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C-H_{\text {alkane }}, H_{2} M O}=a \cos \theta_{C-H_{\text {alkane }}, H_{2} M O} \tag{14.606}
\end{equation*}
$$

Substitution of Eqs. (14.595) and (14.605) into Eq. (14.606) gives:

$$
\begin{equation*}
d_{C-H_{\text {alkane },}, H_{2} M O}=1.35486 a_{0}=7.16963 \times 10^{-11} \mathrm{~m} \tag{14.607}
\end{equation*}
$$

The distance $d_{C-H_{\text {alkane }} 2 s p^{3} H O}$ along the internuclear axis from the origin of the $C$ atom to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{C-H_{\text {alkane }} 2 s p^{3} H O}=d_{C-H_{\text {alkane }}, H_{2} M O}-c^{\prime} \tag{14.608}
\end{equation*}
$$

Substitution of Eqs. (14.596) and (14.605) into Eq. (14.608) gives:

$$
\begin{equation*}
d_{C-H_{\text {alkane }} 2 s p^{3} H O}=0.29933 a_{0}=1.58400 \times 10^{-11} \mathrm{~m} \tag{14.609}
\end{equation*}
$$

The charge-density in each $C-C$-bond MO is increased by a factor of 0.25 with the formation of the $C_{\text {alkane }} 2 s p^{3}$ HOs each having a smaller radius. Using the orbital composition of the $\mathrm{C}-\mathrm{C}$-bond MOs (Eq. (14.504)), $\mathrm{CH}_{3}$ groups (Eq. (14.539)), and the $\mathrm{CH}_{2}$ groups (Eq. (14.591)), the radii of $C 1 s=0.17113 a_{0}$ (Eq. (10.51)), $C_{\text {alkane }} 2 s p^{3}=0.86359 a_{0}$ (Eq. (14.514)), and $C_{\text {alkane }} 2 s p^{3}=C_{\text {methylene }} 2 s p^{3}=0.81549 a_{0}$ (Eq. (14.521)) shells, the parameters of the $C-C$-bonds (Eqs. (13.3-13.4), (14.52314.525), and (14.528-14.538)), the parameters of the $\mathrm{C}-\mathrm{H}$-bond MOs of the $\mathrm{CH}_{3}$ groups (Eqs. (13.3-13.4), (14.544-14.545), and (14.547-14.557)), the parameters of the $\mathrm{C}-\mathrm{H}$-bond MOs of the $\mathrm{CH}_{2}$ groups (Eqs. (13.3-13.4), (14.595-14.597), and (14.599-14.609)), and the bond-angle parameters (Eqs. (14.562-14.574)), the charge-density of the $C_{n} H_{2 n+2}$ MO comprising the linear combination $2 n+2 \quad C-H$-bond MOs and $n-1 \quad C-C$-bond MOs, each bridging one or more methyl or methylene groups is shown for representative cases where data was available [17-18]. Propane, butane, pentane, hexane, heptane, octane, nonane, decane, undecane, dodecane, and octadecane are shown in Figures 14.18-14.28, respectively. Each $C-H$-bond MO comprises a $H_{2}$-type ellipsoidal MO and a $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ having the dimensional diagram shown in Figure 14.16. Each $C-C$ bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {alkane }} 2 s p^{3}$ HOs having the dimensional diagram shown in Figure 14.17.

## ENERGIES OF THE $\mathrm{CH}_{2}$ GROUPS

The energies of each $\mathrm{CH}_{2}$ group of $C_{n} H_{2 n+2}$ are given by the substitution of the semiprincipal axes (Eqs. (14.595-14.596) and (14.599)) into the energy equations of dihydrogen carbide radical (Eqs. (13.510-13.514)), with the exception that $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$ (Eq. (14.512)) replaces $E\left(C, 2 s p^{3}\right)$ in Eq. (13.514):

$$
\begin{align*}
& V_{e}=2(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-70.41425 \mathrm{eV}  \tag{14.610}\\
& V_{p}=\frac{2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=25.78002 \mathrm{eV}  \tag{14.611}\\
& T=2(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=21.06675 \mathrm{eV}  \tag{14.612}\\
& V_{m}=2(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-10.53337 \mathrm{eV}  \tag{14.613}\\
& E_{T_{a l k e n e}}\left(C H_{2}\right)=-\frac{2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.56407 \mathrm{eV}=-49.66493 \mathrm{eV} \tag{14.614}
\end{align*}
$$

where $E_{T_{\text {alkene }}}\left(\mathrm{CH}_{2}\right)$ is given by Eq. (14.592) which is reiteratively matched to Eq. (13.496) within five-significant-figure round off error.

## VIBRATION OF THE ${ }^{12} \mathrm{CH}_{2}$ GROUPS

The vibrational energy levels of the $\mathrm{C}-\mathrm{H}$ bonds of $\mathrm{CH}_{2}$ in $\mathrm{C}_{n} \mathrm{H}_{2 n+2}$ may be solved as two equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERMS OF THE ${ }^{12} \mathrm{CH}_{2}$ GROUPS

The equations of the radiation reaction force of the methylene groups in $C_{n} H_{2 n+2}$ are the same as those of the dihydrogen carbide radical with the substitution of the methylene-group parameters. Using Eq. (13.515), the angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.75 e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}}=2.42751 \times 10^{16} \mathrm{rad} / \mathrm{s} \tag{14.615}
\end{equation*}
$$

where $b$ is given by Eq. (14.599). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 2.42751 \times 10^{16} \mathrm{rad} / \mathrm{s}=15.97831 \mathrm{eV} \tag{14.616}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each $H_{2}$-type MO, for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.616) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-31.63537 \mathrm{eV} \sqrt{\frac{2 e(15.97831 \mathrm{eV})}{m_{e} c^{2}}}=-0.25017 \mathrm{eV} \tag{14.617}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of $\mathrm{CH}_{2}$ due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.617) and $\bar{E}_{\text {Kvib }}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of each $C-H$ bond. Using $\omega_{e}$ given by Eq. (13.458) for $\bar{E}_{\text {Kvib }}$ of the transition state having two independent bonds, $\bar{E}_{\text {alkane osc }}^{\prime}\left({ }^{12} \mathrm{CH}_{2}\right)$ per bond is:

$$
\begin{align*}
& \bar{E}_{\text {alkane osc }}^{\prime}\left({ }^{12} \mathrm{CH}_{2}\right)=\bar{E}_{D}+\bar{E}_{K v i b}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{14.618}\\
& \bar{E}_{\text {alkane osc }}^{\prime}\left({ }^{12} \mathrm{CH}_{2}\right)=-0.25017 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})=-0.07251 \mathrm{eV} \tag{14.619}
\end{align*}
$$

Given that the vibration and reentrant oscillation is for two $\mathrm{C}-\mathrm{H}$ bonds, $\bar{E}_{\text {alkane osc }}\left({ }^{12} \mathrm{CH}_{2}\right)$, is:

$$
\begin{equation*}
\bar{E}_{\text {alkane osc }}\left({ }^{12} \mathrm{CH}_{2}\right)=2\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)=2\left(-0.25017 \mathrm{eV}+\frac{1}{2}(0.35532 \mathrm{eV})\right)=-0.14502 \mathrm{eV} \tag{14.620}
\end{equation*}
$$

## TOTAL BOND ENERGIES OF THE ${ }^{12} \mathrm{CH}_{2}$ GROUPS

$E_{\text {alkaneT }+ \text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right)$, the total energy of each ${ }^{12} \mathrm{CH}_{2}$ group including the Doppler term, is given by the sum of $E_{T_{\text {alkane }}}\left(\mathrm{CH}_{2}\right)$ (Eq. (14.614)) and $\bar{E}_{\text {alkane osc }}\left({ }^{12} \mathrm{CH}_{2}\right)$ given by Eq. (14.620).

$$
\left.\begin{array}{rl}
E_{\text {alkaneT +osc }}\left({ }^{12} \mathrm{CH}_{2}\right)= & V_{e}+T+V_{m}+V_{p}+E\left(C_{\text {alkane }}, 2 s p^{3}\right)+\bar{E}_{\text {alkane osc }}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =E_{T_{\text {alkane }}}\left(\mathrm{CH}_{2}\right)+\bar{E}_{\text {alkane osc }}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& \left(\frac{-2 e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.56407 \mathrm{eV}\right)  \tag{14.622}\\
E_{\text {alkane }+ \text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right) & =\left\{\begin{array}{l}
-2(31.63536831 \mathrm{eV}) \sqrt{\frac{\frac{3}{2} \frac{e^{2}}{4 \pi \varepsilon_{0} b^{3}}}{m_{e}}} \\
m_{e} c^{2}
\end{array} \frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{array}\right\}
$$

From Eqs. (14.620-14.622), the total energy of each ${ }^{12} \mathrm{CH}_{2}$ is:

$$
\begin{align*}
E_{\text {alkaneT } T \text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right) & =-49.66493 \mathrm{eV}+\bar{E}_{\text {alkane osc }}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =-49.66493 \mathrm{eV}-2\left(0.25017 \mathrm{eV}-\frac{1}{2}(0.35532 \mathrm{eV})\right)=-49.80996 \mathrm{eV} \tag{14.623}
\end{align*}
$$

where $\omega_{e}$ given by Eq. (13.458) was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.
The derivation of the total $\mathrm{CH}_{2}$ bond dissociation energy, $E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right)$ follows from that of the bond dissociation energy of dihydrogen carbide radical, $E_{D}\left({ }^{12} \mathrm{CH}_{2}\right)$, given by Eqs. (13.524-13.527). $E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right)$ is given by the sum of the initial $C 2 s p^{3}$ HO energy, $E\left(C, 2 s p^{3}\right)$ (Eq. (14.146)), and two times the energy of the hydrogen atom, $E(H)$ (Eq. (13.154)), minus the sum of $E_{\text {alkaneT }+ \text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right)$ (Eq. (14.623)) and $E$ (magnetic) (Eq. (13.524)):

$$
\begin{equation*}
E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right)=E\left(\mathrm{C}, 2 s p^{3}\right)+2 E(H)-E_{\text {alkaneT }+ \text { osc }}\left({ }^{12} \mathrm{CH}_{2}\right)-E(\text { magnetic }) \tag{14.624}
\end{equation*}
$$

Thus, the total ${ }^{12} \mathrm{CH}_{2}$ bond dissociation energy, $E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right)$ is:

$$
\begin{align*}
E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right) & =-(14.63489 \mathrm{eV}+2(13.59844 \mathrm{eV}))-\left(E_{\text {alkaneT +osc }}\left({ }^{12} \mathrm{CH}_{2}\right)+E(\text { magnetic })\right)  \tag{14.625}\\
& =-41.83177 \mathrm{eV}-(-49.80996 \mathrm{eV}+0.14803 \mathrm{eV})=7.83016 \mathrm{eV}
\end{align*}
$$

## SUM OF THE ENERGIES OF THE $C-C \quad \sigma$ MOs AND THE HOS OF CONTINUOUSCHAIN ALKANES

The energy components of $V_{e}, V_{p}, T, V_{m}$, and $E_{T}$ of the $C-C$-bond MOs are the same as those of the $C H$ MO except that energy of the $C_{\text {alkane }} 2 s p^{3} \mathrm{HO}$ is used. The energies of each $C-C$-bond MO are given by the substitution of the semiprincipal axes (Eqs. (14.523-14.524) and (14.528)) into the energy equations of the $C H$ MO (Eqs. (13.449-13.453)), with the exception that $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$ (Eq. (14.512)) replaces $E\left(C, 2 s p^{3}\right)$ in Eq. (13.453). The total number of $C-C$ bonds of $C_{n} H_{2 n+2}$ is $n-1$. Thus, the energies of the $n-1$ bonds is given by:

$$
\begin{align*}
& V_{e}=(n-1)(0.91771) \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-(n-1) 28.79214 \mathrm{eV}  \tag{14.626}\\
& V_{p}=\frac{(n-1) e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}=(n-1) 9.33352 \mathrm{eV}  \tag{14.627}\\
& T=(n-1)(0.91771) \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=(n-1) 6.77464 \mathrm{eV}  \tag{14.628}\\
& V_{m}=(n-1)(0.91771) \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-(n-1) 3.38732 \mathrm{eV}  \tag{14.629}\\
& E_{T_{\text {alkeme }}}(C-C, \sigma)=-\frac{(n-1) e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]-15.56407 \mathrm{eV}=-(n-1) 31.63537 \mathrm{eV} \tag{14.630}
\end{align*}
$$

where $E_{T_{\text {alkane }}}(C-C, \sigma)$ is the total energy of the $C-C \sigma$ MOs given by Eq. (14.520) which is reiteratively matched to Eq. (13.75) within five-significant-figure round off error.

Since there are two carbon atoms per bond, the number of $C-C$ bonds is $n-1$, and the energy change of each $C 2 s p^{3}$ shell due to the decrease in radius with the formation of each $C-C$-bond MO is $E_{T_{\text {alkane }}}\left(C-C, 2 s p^{3}\right)$ (Eq. (14.517)), the total energy of the $C-C$-bond MOs, $E_{T_{\text {alkane }}}(C-C)$, is given by the sum of $2(n-1) E_{T_{\text {alkane }}}\left(C-C, 2 s p^{3}\right)$ and $E_{T_{\text {alkane }}}(C-C, \sigma)$, the $\sigma$ MO contribution given by Eq. (14.630).

$$
\begin{align*}
E_{T_{\text {alkane }}}(C-C) & =2(n-1) E_{T_{\text {alkane }}}\left(C-C, 2 s p^{3}\right)+E_{T_{\text {alkane }}}(C-C, \sigma) \\
& =(n-1)\left(\begin{array}{l}
2(-0.92918 \mathrm{eV}) \\
\left.+\left(\begin{array}{l}
-\frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a a_{0}}} \\
-15.56407 \mathrm{eV}
\end{array}(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{a a_{0}}}{a-\sqrt{a a_{0}}}-1\right]\right) \\
\\
\end{array}\right)(n-1)(2(-0.92918 \mathrm{eV})+(-31.63537 \mathrm{eV}))=-(n-1) 33.49373 \mathrm{eV} \tag{14.631}
\end{align*}
$$

## VIBRATION OF CONTINUOUS-CHAIN ALKANES

The vibrational energy levels of the $C-C$ bonds of $C_{n} H_{2 n+2}$ may be solved as $n-1$ sets of coupled carbon harmonic oscillators wherein each carbon is further coupled to two or three equivalent $H$ harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

## THE DOPPLER ENERGY TERMS OF THE $C-C$-BOND MOs OF CONTINUOUS-CHAIN ALKANES

The equations of the radiation reaction force of each symmetrical $C-C$-bond MO are given by Eqs. (11.231-11.233), except the force-constant factor is 0.5 based on the force constant $k^{\prime}$ of Eq. (14.152), and the $C-C$-bond MO parameters are used. The angular frequency of the reentrant oscillation in the transition state is:

$$
\begin{equation*}
\omega=\sqrt{\frac{\frac{0.5 e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}=9.43699 \times 10^{15} \mathrm{rad} / \mathrm{s} \tag{14.632}
\end{equation*}
$$

where $a$ is given by Eq. (14.523). The kinetic energy, $E_{K}$, is given by Planck's equation (Eq. (11.127)).

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar 9.43699 \times 10^{15} \mathrm{rad} / \mathrm{s}=6.21159 \mathrm{eV} \tag{14.633}
\end{equation*}
$$

In Eq. (11.181), substitution of $E_{T_{\text {alkane }}}(C-C)$ (Eq. (14.631)) with $n=2$ for $E_{h v}$, the mass of the electron, $m_{e}$, for $M$, and the kinetic energy given by Eq. (14.633) for $\bar{E}_{K}$ gives the Doppler energy of the electrons of each of the bonds for the reentrant orbit:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}=-33.49373 \mathrm{eV} \sqrt{\frac{2 e(6.21159 \mathrm{eV})}{m_{e} c^{2}}}=-0.16515 \mathrm{eV} \tag{14.634}
\end{equation*}
$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of each $C-C$-bond MO due to the reentrant orbit of the bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{\text {osc }}$, is given by the sum of the corresponding energies, $\bar{E}_{D}$ given by Eq. (14.634) and $\bar{E}_{K v i b}$, the average kinetic energy of vibration which is $1 / 2$ of the vibrational energy of each $C-C$ bond. Using the ethane experimental $C-C E_{v i b}\left(v_{3}\right)$ of $993 \mathrm{~cm}^{-1}(0.12312 \mathrm{eV})$ [10] for $\bar{E}_{K v i b}$ of the transition state having $n-1$ independent bonds, $\bar{E}_{\text {alkane osc }}^{\prime}(C-C, \sigma)$ per bond is:

$$
\begin{align*}
& \bar{E}_{\text {alkane osc }}^{\prime}(C-C, \sigma)=\bar{E}_{D}+\bar{E}_{\text {Kiib }}=\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}  \tag{14.635}\\
& \bar{E}_{\text {alkane osc }}^{\prime}(C-C, \sigma)=-0.16515 \mathrm{eV}+\frac{1}{2}(0.12312 \mathrm{eV})=-0.10359 \mathrm{eV} \tag{14.636}
\end{align*}
$$

Given that the vibration and reentrant oscillation is for $n-1 C-C$ bonds, $\bar{E}_{\text {alkane osc }}(C-C, \sigma)$, is:

$$
\begin{align*}
\bar{E}_{\text {alkane osc }}(C-C, \sigma) & =(n-1)\left(\bar{E}_{D}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)  \tag{14.637}\\
& =(n-1)\left(-0.16515 \mathrm{eV}+\frac{1}{2}(0.12312 \mathrm{eV})\right)=-(n-1) 0.10359 \mathrm{eV}
\end{align*}
$$

## TOTAL ENERGIES OF THE $C-C$-BOND MOs OF CONTINUOUS-CHAIN ALKANES

$E_{\text {alkaneT+osc }}(C-C)$, the total energy of the $n-1$ bonds of the $C-C$-bond MOs including the Doppler term, is given by the sum of $E_{T_{\text {alkane }}}(C-C)$ (Eq. (14.631)) and $\bar{E}_{\text {alkane osc }}(C-C, \sigma)$ given by Eq. (14.637).

$$
\begin{align*}
& E_{\text {alkaneT+osc }}(C-C)=\left((n-1)\binom{V_{e}+T+V_{m}+V_{p}+E\left(C_{\text {alkane }}, 2 s p^{3}\right)}{+2 E_{\text {alkkane }}\left(C-C, 2 s p^{3}\right)}+\bar{E}_{\text {alkane osc }}(C-C, \sigma)\right) \\
& =E_{T_{\text {alkane }}}(C-C, \sigma)+2(n-1) E_{T_{\text {alkane }}}\left(C-C, 2 s p^{3}\right)+\bar{E}_{\text {alkane osc }}(C-C, \sigma)  \tag{14.638}\\
& =E_{T_{\text {alkane }}}(C-C)+\bar{E}_{\text {alkane osc }}(C-C, \sigma) \\
& E_{\text {alkane } T \text { osc } c}(C-C)=(n-1)\left\{\begin{array}{l}
\binom{\frac{-e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[(0.91771)\left(2-\frac{1}{2} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]}{-15.56407 e V+2 E_{T_{\text {alkane }}}\left(C-C, 2 s p^{3}\right)} \\
\left.1+\sqrt{\frac{2 \hbar \sqrt{\frac{\frac{1}{2} \frac{e^{2}}{2 \pi \varepsilon_{0} a^{3}}}{m_{e}}}}{m_{e} c^{2}}}\right)+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}
\end{array}\right\}  \tag{14.639}\\
& =(n-1)\left(-33.49373 \mathrm{eV}-0.16515 \mathrm{eV}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right)
\end{align*}
$$

From Eqs. (14.637-14.639), the total energy of the $n-1$ bonds of the $C-C$-bond MOs is:

$$
\begin{align*}
E_{\text {alkane } T \text { osc }}(C-C) & =(n-1)\left(-31.63537 \mathrm{eV}+2 E_{T_{\text {alkane }}}\left(C-C, 2 s p^{3}\right)\right)+\bar{E}_{\text {alkane osc }}(C-C, \sigma) \\
& =(n-1)\binom{-31.63537 \mathrm{eV}+2(-0.92918 \mathrm{eV})}{-0.16515 \mathrm{eV}+\frac{1}{2}(0.12312 \mathrm{eV})}=-(n-1) 33.59732 \mathrm{eV} \tag{14.640}
\end{align*}
$$

where the experimental $E_{v i b}$ was used for the $\hbar \sqrt{\frac{k}{\mu}}$ term.

## TOTAL BOND ENERGY OF THE $C-C$ BONDS OF CONTINUOUS-CHAIN ALKANES

Since there are two carbon atoms per bond and the number of $C-C$ bonds is $n-1$, the total bond energy of the $C-C$ bonds of $C_{n} H_{2 n+2}, E_{D}(C-C)_{n-1}$, is given by $2(n-1) E\left(C, 2 s p^{3}\right)$ minus $E_{\text {alkaneT }+ \text { osc }}(C-C)$ (Eq. (14.640)) where $E\left(C, 2 s p^{3}\right)$ (Eq. (14.146)) is the initial energy of each $C 2 s p^{3} \mathrm{HO}$ of the $\mathrm{CH}_{3}$ and $\mathrm{CH}_{2}$ groups that bond to the $\mathrm{C}-\mathrm{C}$ bonds. Thus, the total dissociation energy of the $\mathrm{C}-\mathrm{C}$ bonds of $\mathrm{C}_{n} \mathrm{H}_{2 n+2}$, is:

$$
\begin{align*}
E_{D}(C-C)_{n-1} & =2(n-1)\left(E\left(C, 2 s p^{3}\right)\right)-\left(E_{\text {alakneT Tosc }}(C-C)\right) \\
& =2(n-1)(-14.63489 \mathrm{eV})-(n-1)(-33.59732 \mathrm{eV})  \tag{14.641}\\
& =(n-1)(2(-14.63489 \mathrm{eV})-(-33.59732 \mathrm{eV}))=(n-1)(4.32754 \mathrm{eV})
\end{align*}
$$

## TOTAL ENERGY OF CONTINUOUS-CHAIN ALKANES

$E_{D}\left(C_{n} H_{2 n+2}\right)$, the total bond dissociation energy of $C_{n} H_{2 n+2}$, is given as the sum of the energy components due to the two methyl groups, $n-2$ methylene groups, and $n-1 \quad C-C$ bonds where each energy component is given by Eqs. (14.590), (14.625), and (14.641), respectively. Thus, the total bond dissociation energy of $C_{n} H_{2 n+2}$ is:

$$
\begin{align*}
E_{D}\left(C_{n} H_{2 n+2}\right) & =E_{D}(C-C)_{n-1}+2 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{3}\right)+(n-2) E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right)  \tag{14.642}\\
& =(n-1)(4.32754 \mathrm{eV})+2(12.49186 \mathrm{eV})+(n-2)(7.83016 \mathrm{eV})
\end{align*}
$$

The experimental total bond dissociation energy of $C_{n} H_{2 n+2}, E_{D_{\text {exp }}}\left(C_{n} H_{2 n+2}\right)$, is given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{n} H_{2 n+2}(\right.\right.$ gas $\left.)\right)$ ) and the sum of the enthalpy of the formation of the reactant gaseous carbons $\left(\Delta H_{f}(C(g a s))\right)$ and hydrogen $\left(\Delta H_{f}(H(g a s))\right)$ atoms:

$$
\begin{align*}
E_{D_{\text {epp }}}\left(C_{n} H_{2 n+2}\right) & =-\left\{\Delta H_{f}\left(C_{n} H_{2 n+2}(\text { gas })\right)-\left[n \Delta H_{f}(C(\text { gas }))+(2 n+2) \Delta H_{f}(H(\text { gas }))\right]\right\}  \tag{14.643}\\
& =-\left\{\Delta H_{f}\left(C_{n} H_{2 n+2}(\text { gas })\right)-[n 7.42774 \mathrm{eV}+(2 n+2) 2.259353 \mathrm{eV}]\right\}
\end{align*}
$$

where the heats of formation atomic carbon and hydrogen gas are given by [17-18]:

$$
\begin{equation*}
\Delta H_{f}(C(\text { gas }))=716.68 \mathrm{~kJ} / \text { mole }(7.42774 \mathrm{eV} / \text { atom }) \tag{14.644}
\end{equation*}
$$

$$
\begin{equation*}
\Delta H_{f}(H(\text { gas }))=217.998 \mathrm{~kJ} / \text { mole }(2.259353 \mathrm{eV} / \text { atom }) \tag{14.645}
\end{equation*}
$$

Using the corresponding experimental $\Delta H_{f}\left(C_{n} H_{2 n+2}(\right.$ gas $\left.)\right)$ [18], $E_{D}\left(C_{n} H_{2 n+2}\right)$ was determined for propane, butane, pentane, hexane, heptane, octane, nonane, decane, undecane, dodecane, and octadecane in the corresponding sections, and the results of the determination of the total energies are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

Using the results for $C_{n} H_{2 n+2}$ and the functional groups as basis sets that are linearly combined, the exact solution for the dimensional parameters, charge density functions, and energies of all molecules can be obtained. For example, one or more of the hydrogen atoms of the solution for $C_{n} H_{2 n+2}$ can be substituted with one or more of the previously solved functional groups or derivative functional groups to give a desired molecule. The solution is given by energy matching each group to $C_{n} H_{2 n+2}$. Substitution of one or more $H$ 's of $C_{n} H_{2 n+2}$ with functional groups from the list of $\mathrm{CH}_{3}$, other $\mathrm{C}_{n} \mathrm{H}_{2 n+2}$ groups, $\mathrm{H}_{2} \mathrm{C}=\mathrm{CH}_{2}$, $\mathrm{HC} \equiv \mathrm{CH}, \mathrm{F}, \mathrm{Cl}, \mathrm{O}, \mathrm{OH}, \mathrm{NH}, \mathrm{NH}_{2}, \mathrm{CN}, \mathrm{NO}, \mathrm{NO}_{2}, \mathrm{CO}, \mathrm{CO}_{2}$, and $\mathrm{C}_{6} \mathrm{H}_{6}$ give the solutions of branched alkanes, alkenes, and alkynes, alkyl halides, ethers, alcohols, amides, amines, nitriles, alkyl nitrosos, alkyl nitrates, aldehydes, ketones, carbolylic acids, esters, and substituted aromatics.

## PROPANE ( $\mathrm{C}_{3} \mathrm{H}_{8}$ )

Using Eq. (14.642) with $n=3$, the total bond dissociation energy of $C_{3} H_{8}$ is:

$$
\begin{align*}
E_{D}\left(C_{3} H_{8}\right) & =E_{D}(\mathrm{C}-\mathrm{C})_{2}+2 E_{D_{\text {alkawe }}}\left({ }^{12} \mathrm{CH}_{3}\right)+E_{D_{\text {alkaee }}}\left({ }^{12} \mathrm{CH}_{2}\right)  \tag{14.646}\\
& =(2)(4.32754 \mathrm{eV})+(2)(12.49186 \mathrm{eV})+(1)(7.83016 \mathrm{eV})=41.46896 \mathrm{eV}
\end{align*}
$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{3} H_{8}, E_{D_{\text {exp }}}\left(C_{3} H_{8}\right)$, given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{3} H_{8}(g a s)=-1.0758 \mathrm{eV}\right)\right)$ [18] and the sum of the enthalpy of the formation of the gaseous carbons $\left(\Delta H_{f}(C(\right.$ gas $\left.))\right)$ and hydrogen $\left(\Delta H_{f}(H(\right.$ gas $\left.))\right)$ atoms is:

$$
\begin{align*}
E_{D_{\text {epp }}}\left(C_{3} H_{8}\right) & =-\left\{\Delta H_{f}\left(C_{3} H_{8}(\text { gas })\right)-\left[3 \Delta H_{f}(C(\text { gas }))+8 \Delta H_{f}(H(\text { gas }))\right]\right\}  \tag{14.647}\\
& =-\{-1.0758 \mathrm{eV}-[(3) 7.42774 \mathrm{eV}+(8) 2.259353 \mathrm{eV}]\}=41.434 \mathrm{eV}
\end{align*}
$$

The charge-density of the $C_{3} H_{8}$ molecular orbital (MO) comprising a linear combination of two methyl groups and one methylene group is shown in Figure 14.18.

Figure 14.18. $C_{3} H_{8}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl groups and one methylene group. (A) Color scale, translucent view of the charge-density of the $C-C$-bond and $C-H$-bond MOs and the $C_{\text {propane }} 2 s p^{3}$ HOs. Each $C-C$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {propane }} 2 s p^{3}$ HOs. For each $\mathrm{C}-\mathrm{H}$ and the $\mathrm{C}-\mathrm{C}$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {propane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {propane }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown. (B) Opaque view highlighting the $\mathrm{C}-\mathrm{C}$-bond MOs of the charge-density of the $\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{MO}$.

B

$0 \square 1 \mathrm{e} / \AA^{2}$

## BUTANE ( $C_{4} H_{10}$ )

Using Eq. (14.642) with $n=4$, the total bond dissociation energy of $C_{4} H_{10}$ is:

$$
\begin{align*}
E_{D}\left(C_{4} H_{10}\right) & =E_{D}(\mathrm{C}-\mathrm{C})_{3}+2 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{3}\right)+2 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =(3)(4.32754 \mathrm{eV})+(2)(12.49186 \mathrm{eV})+(2)(7.83016 \mathrm{eV})  \tag{14.648}\\
& =53.62666 \mathrm{eV}
\end{align*}
$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{4} H_{10}, E_{D_{\text {cpp }}}\left(C_{4} H_{10}\right)$, given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{4} H_{10}(\mathrm{gas})=-1.3028 \mathrm{eV}\right)\right)$ [18] and the sum of the enthalpy of the formation of the gaseous carbons $\left(\Delta H_{f}(C(\right.$ gas $\left.))\right)$ and hydrogen $\left(\Delta H_{f}(H(\right.$ gas $\left.))\right)$ atoms is:

$$
\begin{align*}
E_{D_{\text {exp }}}\left(C_{4} H_{10}\right) & =-\left\{\Delta H_{f}\left(C_{4} H_{10}(\text { gas })\right)-\left[4 \Delta H_{f}(C(\text { gas }))+10 \Delta H_{f}(H(\text { gas }))\right]\right\} \\
& =-\{-1.3028 \mathrm{eV}-[(4) 7.42774 \mathrm{eV}+(10) 2.259353 \mathrm{eV}]\}  \tag{14.649}\\
& =53.61 \mathrm{eV}
\end{align*}
$$

The charge-density of the $C_{4} H_{10}$ molecular orbital (MO) comprising a linear combination of two methyl and two methylene groups is shown in Figure 14.19.

Figure 14.19. $C_{4} H_{10}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and two methylene groups. (A) Color scale, translucent view of the charge-density of the $C-C$-bond and $C-H$-bond MOs and the $C_{\text {butane }} 2 s p^{3}$ HOs. Each $C-C$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {butane }} 2 s p^{3}$ HOs. For each $\mathrm{C}-\mathrm{H}$ and the $\mathrm{C}-\mathrm{C}$ bond, the ellipsoidal surface of the $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the $C_{\text {butane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {butane }} 2 s p^{3}$ HO shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown. (B) Opaque view highlighting the $C-C$-bond MOs of the charge-density of the $C_{4} H_{10}$ MO.

## PENTANE ( $\mathrm{C}_{5} \mathrm{H}_{12}$ )

Using Eq. (14.642) with $n=5$, the total bond dissociation energy of $C_{5} H_{12}$ is:

$$
\begin{align*}
E_{D}\left(C_{5} H_{12}\right) & =E_{D}(\mathrm{C}-\mathrm{C})_{4}+2 E_{D_{\text {alkere }}}\left({ }^{12} \mathrm{CH}_{3}\right)+3 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =(4)(4.32754 \mathrm{eV})+(2)(12.49186 \mathrm{eV})+(3)(7.83016 \mathrm{eV})  \tag{14.650}\\
& =65.78436 \mathrm{eV}
\end{align*}
$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{5} H_{12}, E_{D_{\text {exp }}}\left(C_{5} H_{12}\right)$, given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{5} H_{12}(g a s)=-1.5225 \mathrm{eV}\right)\right)$ [18] and the sum of the enthalpy of the formation of the gaseous carbons $\left(\Delta H_{f}(C(g a s))\right)$ and hydrogen $\left(\Delta H_{f}(H(g a s))\right)$ atoms is:

$$
\begin{align*}
E_{D_{\text {app }}}\left(C_{5} H_{12}\right) & =-\left\{\Delta H_{f}\left(C_{5} H_{12}(\text { gas })\right)-\left[5 \Delta H_{f}(C(\text { gas }))+12 \Delta H_{f}(H(\text { gas }))\right]\right\} \\
& =-\{-1.5225 \mathrm{eV}-[(5) 7.42774 \mathrm{eV}+(12) 2.259353 \mathrm{eV}]\}  \tag{14.651}\\
& =65.77 \mathrm{eV}
\end{align*}
$$

The charge-density of the $C_{5} H_{12}$ molecular orbital (MO) comprising a linear combination of two methyl and three methylene groups is shown in Figure 14.20.

Figure 14.20. $C_{5} H_{12}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and three methylene groups. (A) Color scale, translucent view of the charge-density of the $C-C$-bond and $C-H$-bond MOs and the $C_{\text {pentane }} 2 s p^{3}$ HOs. Each $C-C$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {pentane }} 2 s p^{3}$ HOs. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {pentane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {pentane }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown. (B) Opaque view highlighting the $C-C$-bond MOs of the charge-density of the $C_{5} H_{12}$ MO.

## HEXANE ( $C_{6} H_{14}$ )

Using Eq. (14.642) with $n=6$, the total bond dissociation energy of $C_{6} H_{14}$ is:

$$
\begin{align*}
E_{D}\left(C_{6} H_{14}\right) & =E_{D}(\mathrm{C}-\mathrm{C})_{5}+2 E_{D_{\text {alkewe }}}\left({ }^{12} \mathrm{CH}_{3}\right)+4 E_{D_{\text {alkeere }}}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =(5)(4.32754 \mathrm{eV})+(2)(12.49186 \mathrm{eV})+(4)(7.83016 \mathrm{eV})  \tag{14.652}\\
& =77.94206 \mathrm{eV}
\end{align*}
$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{6} H_{14}, E_{D_{\text {cpp }}}\left(C_{6} H_{14}\right)$, given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{6} H_{14}(\mathrm{gas})=-1.7298 \mathrm{eV}\right)\right)$ [18] and the sum of the enthalpy of the formation of the gaseous carbons $\left(\Delta H_{f}(C(\right.$ gas $\left.))\right)$ and hydrogen $\left(\Delta H_{f}(H(\right.$ gas $\left.))\right)$ atoms is:

$$
\begin{align*}
E_{D_{\text {exp }}}\left(C_{6} H_{14}\right) & =-\left\{\Delta H_{f}\left(C_{6} H_{14}(\text { gas })\right)-\left[6 \Delta H_{f}(C(\text { gas }))+14 \Delta H_{f}(H(\text { gas }))\right]\right\} \\
& =-\{-1.7298 \mathrm{eV}-[(6) 7.42774 \mathrm{eV}+(14) 2.259353 \mathrm{eV}]\}  \tag{14.653}\\
& =77.93 \mathrm{eV}
\end{align*}
$$

The charge-density of the $C_{6} H_{14}$ molecular orbital (MO) comprising a linear combination of two methyl and four methylene groups is shown in Figure 14.21.

Figure 14.21. $C_{6} H_{14}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and four methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$ bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {hexane }} 2 s p^{3}$ HOs. (B) Translucent view high-lighting the $C-C$ bond MOs of the charge-density of the $C_{6} H_{14}$ MO. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {hexane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {hexane }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown.

## HEPTANE ( $\mathrm{C}_{7} \mathrm{H}_{16}$ )

Using Eq. (14.642) with $n=7$, the total bond dissociation energy of $C_{7} H_{16}$ is:

$$
\begin{align*}
E_{D}\left(C_{7} H_{16}\right) & =E_{D}(\mathrm{C}-\mathrm{C})_{6}+2 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{3}\right)+5 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =(6)(4.32754 \mathrm{eV})+(2)(12.49186 \mathrm{eV})+(5)(7.83016 \mathrm{eV})  \tag{14.654}\\
& =90.09976 \mathrm{eV}
\end{align*}
$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{7} H_{16}, E_{D_{\text {epp }}}\left(C_{7} H_{16}\right)$, given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{7} H_{16}(\mathrm{gas})=-1.9443 \mathrm{eV}\right)\right)$ [18] and the sum of the enthalpy of the formation of the gaseous carbons $\left(\Delta H_{f}(C(g a s))\right)$ and hydrogen $\left(\Delta H_{f}(H(g a s))\right)$ atoms is:

$$
\begin{align*}
E_{D_{\exp }}\left(C_{7} H_{16}\right) & =-\left\{\Delta H_{f}\left(C_{7} H_{16}(\text { gas })\right)-\left[7 \Delta H_{f}(C(\text { gas }))+16 \Delta H_{f}(H(\text { gas }))\right]\right\} \\
& =-\{-1.9443 \mathrm{eV}-[(7) 7.42774 \mathrm{eV}+(16) 2.259353 \mathrm{eV}]\}  \tag{14.655}\\
& =90.09 \mathrm{eV}
\end{align*}
$$

The charge-density of the $C_{7} H_{16}$ MO comprising a linear combination of two methyl and five methylene groups is shown in Figure 14.22.

Figure 14.22. $C_{7} H_{16} \mathrm{MO}$ comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and five methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$ bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {heptane }} 2 s p^{3}$ HOs. (B) Translucent view high-lighting the $C-C$ bond MOs of the charge-density of the $C_{7} H_{16}$ MO. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {heptane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {heptane }} 2 s p^{3}$ HO shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown.

## OCTANE ( $\mathrm{C}_{8} \mathrm{H}_{18}$ )

Using Eq. (14.642) with $n=8$, the total bond dissociation energy of $C_{8} H_{18}$ is:

$$
\begin{align*}
E_{D}\left(C_{8} H_{18}\right) & =E_{D}(\mathrm{C}-\mathrm{C})_{7}+2 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{3}\right)+6 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =(7)(4.32754 \mathrm{eV})+(2)(12.49186 \mathrm{eV})+(6)(7.83016 \mathrm{eV})  \tag{14.656}\\
& =102.25746 \mathrm{eV}
\end{align*}
$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{8} H_{18}, E_{D_{\text {epp }}}\left(C_{8} H_{18}\right)$, given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{8} H_{18}(\mathrm{gas})=-2.1609 \mathrm{eV}\right)\right)$ [18] and the sum of the enthalpy of the formation of the gaseous carbons $\left(\Delta H_{f}(C(\right.$ gas $\left.))\right)$ and hydrogen $\left(\Delta H_{f}(H(\right.$ gas $\left.))\right)$ atoms is:

$$
\begin{align*}
E_{D_{\exp }}\left(C_{8} H_{18}\right) & =-\left\{\Delta H_{f}\left(C_{8} H_{18}(\text { gas })\right)-\left[8 \Delta H_{f}(C(\text { gas }))+18 \Delta H_{f}(H(\text { gas }))\right]\right\} \\
& =-\{-2.1609 \mathrm{eV}-[(8) 7.42774 \mathrm{eV}+(18) 2.259353 \mathrm{eV}]\}  \tag{14.657}\\
& =102.25 \mathrm{eV}
\end{align*}
$$

The charge-density of the $C_{8} H_{18}$ MO comprising a linear combination of two methyl and six methylene groups is shown in Figure 14.23.

Figure 14.23. $C_{8} H_{18}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and six methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$-bond MO comprises a $\mathrm{H}_{2}$-type ellipsoidal MO bridging two $C_{\text {octane }} 2 s p^{3}$ HOs. (B) Translucent view high-lighting the $\mathrm{C}-\mathrm{C}$-bond MOs of the charge-density of the $C_{8} H_{18} \mathrm{MO}$. For each $\mathrm{C}-\mathrm{H}$ and the $\mathrm{C}-\mathrm{C}$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {octane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {octane }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown.

## NONANE $\left(C_{9} H_{20}\right)$

Using Eq. (14.642) with $n=9$, the total bond dissociation energy of $C_{9} H_{20}$ is:

$$
\begin{align*}
E_{D}\left(C_{9} H_{20}\right) & =E_{D}(\mathrm{C}-\mathrm{C})_{8}+2 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{3}\right)+7 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =(8)(4.32754 \mathrm{eV})+(2)(12.49186 \mathrm{eV})+(7)(7.83016 \mathrm{eV})  \tag{14.658}\\
& =114.41516 \mathrm{eV}
\end{align*}
$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{9} H_{20}, E_{D_{\text {epp }}}\left(C_{9} H_{20}\right)$, given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{9} H_{20}(\mathrm{gas})=-2.3651 \mathrm{eV}\right)\right)$ [18] and the sum of the enthalpy of the formation of the gaseous carbons $\left(\Delta H_{f}(C(g a s))\right)$ and hydrogen $\left(\Delta H_{f}(H(g a s))\right)$ atoms is:

$$
\begin{align*}
E_{D_{\exp }}\left(C_{9} H_{20}\right) & =-\left\{\Delta H_{f}\left(C_{9} H_{20}(\text { gas })\right)-\left[9 \Delta H_{f}(C(\text { gas }))+20 \Delta H_{f}(H(\text { gas }))\right]\right\} \\
& =-\{-2.3651 \mathrm{eV}-[(9) 7.42774 \mathrm{eV}+(20) 2.259353 \mathrm{eV}]\}  \tag{14.659}\\
& =114.40 \mathrm{eV}
\end{align*}
$$

The charge-density of the $C_{9} H_{20}$ MO comprising a linear combination of two methyl and seven methylene groups is shown in Figure 14.24.

Figure 14.24. $C_{9} H_{20}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and seven methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$ bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {nonane }} 2 s p^{3}$ HOs. (B) Translucent view high-lighting the $C-C$ bond MOs of the charge-density of the $C_{9} H_{20}$ MO. For each $\mathrm{C}-\mathrm{H}$ and the $\mathrm{C}-\mathrm{C}$ bond, the ellipsoidal surface of the $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the $C_{\text {nonane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {nonane }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown.

## DECANE ( $C_{10} H_{22}$ )

Using Eq. (14.642) with $n=10$, the total bond dissociation energy of $C_{10} H_{22}$ is:

$$
\begin{align*}
E_{D}\left(C_{10} H_{22}\right) & =E_{D}(\mathrm{C}-\mathrm{C})_{9}+2 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{3}\right)+8 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =(9)(4.32754 \mathrm{eV})+(2)(12.49186 \mathrm{eV})+(8)(7.83016 \mathrm{eV})  \tag{14.660}\\
& =126.57286 \mathrm{eV}
\end{align*}
$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{10} H_{22}, E_{D_{\text {exp }}}\left(C_{10} H_{22}\right)$, given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{10} H_{22}(\mathrm{gas})=-2.5858 \mathrm{eV}\right)\right)$ [18] and the sum of the enthalpy of the formation of the gaseous carbons $\left(\Delta H_{f}(C(\right.$ gas $\left.))\right)$ and hydrogen $\left(\Delta H_{f}(H(\right.$ gas $\left.))\right)$ atoms is:

$$
\begin{align*}
E_{D_{\text {exp }}}\left(C_{10} H_{22}\right) & =-\left\{\Delta H_{f}\left(C_{10} H_{22}(\text { gas })\right)-\left[10 \Delta H_{f}(C(\text { gas }))+22 \Delta H_{f}(H(\text { gas }))\right]\right\} \\
& =-\{-2.5858 \mathrm{eV}-[(10) 7.42774 \mathrm{eV}+(22) 2.259353 \mathrm{eV}]\}  \tag{14.661}\\
& =126.57 \mathrm{eV}
\end{align*}
$$

The charge-density of the $C_{10} H_{22}$ molecular orbital (MO) comprising a linear combination of two methyl and eight methylene groups is shown in Figure 14.25.

Figure 14.25. $C_{10} H_{22}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and eight methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$ bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {decane }} 2 s p^{3}$ HOs. (B) Translucent view high-lighting the $C-C$ bond MOs of the charge-density of the $C_{10} H_{22} \mathrm{MO}$. For each $\mathrm{C}-\mathrm{H}$ and the $\mathrm{C}-\mathrm{C}$ bond, the ellipsoidal surface of the $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the $C_{\text {decane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {decane }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown.

## UNDECANE ( $\mathrm{C}_{11} \mathrm{H}_{24}$ )

Using Eq. (14.642) with $n=11$, the total bond dissociation energy of $C_{11} H_{24}$ is:

$$
\begin{align*}
E_{D}\left(C_{11} H_{24}\right) & =E_{D}(\mathrm{C}-\mathrm{C})_{10}+2 E_{D_{\text {alhane }}}\left({ }^{12} \mathrm{CH}_{3}\right)+9 E_{D_{\text {alhane }}}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =(10)(4.32754 \mathrm{eV})+(2)(12.49186 \mathrm{eV})+(9)(7.83016 \mathrm{eV})  \tag{14.662}\\
& =138.73056 \mathrm{eV}
\end{align*}
$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{11} H_{24}, E_{D_{\text {epp }}}\left(C_{11} H_{24}\right)$, given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{11} H_{24}(\right.\right.$ gas $\left.\left.)=-2.8066 \mathrm{eV}\right)\right)$ [18] and the sum of the enthalpy of the formation of the gaseous carbons $\left(\Delta H_{f}(C(\right.$ gas $\left.))\right)$ and hydrogen $\left(\Delta H_{f}(H(\right.$ gas $\left.))\right)$ atoms is:

$$
\begin{align*}
E_{D_{\exp }}\left(C_{11} H_{24}\right) & =-\left\{\Delta H_{f}\left(C_{11} H_{24}(\text { gas })\right)-\left[11 \Delta H_{f}(C(\text { gas }))+24 \Delta H_{f}(H(\text { gas }))\right]\right\} \\
& =-\{-2.8066 \mathrm{eV}-[(11) 7.42774 \mathrm{eV}+(24) 2.259353 \mathrm{eV}]\}  \tag{14.663}\\
& =138.736 \mathrm{eV}
\end{align*}
$$

The charge-density of the $C_{11} H_{24}$ MO comprising a linear combination of two methyl and nine methylene groups is shown in Figure 14.26.

Figure 14.26. $C_{11} H_{24}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and nine methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$ bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {undecane }} 2 s p^{3} \mathrm{HOs}$. (B) Translucent view high-lighting the $\mathrm{C}-\mathrm{C}$ bond MOs of the charge-density of the $C_{11} H_{24} \mathrm{MO}$. For each $\mathrm{C}-\mathrm{H}$ and the $\mathrm{C}-\mathrm{C}$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {undecane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {undecane }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown.

## DODECANE ( $\mathrm{C}_{12} \mathrm{H}_{26}$ )

Using Eq. (14.642) with $n=12$, the total bond dissociation energy of $C_{12} H_{26}$ is:

$$
\begin{align*}
E_{D}\left(C_{12} H_{26}\right) & =E_{D}(\mathrm{C}-\mathrm{C})_{11}+2 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{3}\right)+10 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =(11)(4.32754 \mathrm{eV})+(2)(12.49186 \mathrm{eV})+(10)(7.83016 \mathrm{eV})  \tag{14.664}\\
& =150.88826 \mathrm{eV}
\end{align*}
$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{12} H_{26}, E_{D_{\text {exp }}}\left(C_{12} H_{26}\right)$, given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{12} H_{26}(g a s)=-2.9994 \mathrm{eV}\right)\right)$ [18] and the sum of the enthalpy of the formation of the gaseous carbons $\left(\Delta H_{f}(C(\right.$ gas $\left.))\right)$ and hydrogen $\left(\Delta H_{f}(H(\right.$ gas $\left.))\right)$ atoms is:

$$
\begin{align*}
E_{D_{\text {exp }}}\left(C_{12} H_{26}\right) & =-\left\{\Delta H_{f}\left(C_{12} H_{26}(\text { gas })\right)-\left[12 \Delta H_{f}(C(\text { gas }))+26 \Delta H_{f}(H(\text { gas }))\right]\right\} \\
& =-\{-2.9994 \mathrm{eV}-[(12) 7.42774 \mathrm{eV}+(26) 2.259353 \mathrm{eV}]\}  \tag{14.665}\\
& =150.88 \mathrm{eV}
\end{align*}
$$

The charge-density of the $C_{12} H_{26} \mathrm{MO}$ comprising a linear combination of two methyl and ten methylene groups is shown in Figure 14.27.

Figure 14.27. $C_{12} H_{26}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and ten methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$-bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {dodecane }} 2 s p^{3}$ HOs. (B) Translucent view high-lighting the $C-C$-bond MOs of the charge-density of the $C_{12} H_{26}$ MO. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {dodecane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {dodecane }} 2 s p^{3}$ HO shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown.

## OCTADECANE ( $C_{18} H_{38}$ )

Using Eq. (14.642) with $n=18$, the total bond dissociation energy of $C_{18} H_{38}$ is:

$$
\begin{align*}
E_{D}\left(C_{18} H_{38}\right) & =E_{D}(\mathrm{C}-\mathrm{C})_{17}+2 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{3}\right)+16 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right) \\
& =(17)(4.32754 \mathrm{eV})+(2)(12.49186 \mathrm{eV})+(16)(7.83016 \mathrm{eV})  \tag{14.666}\\
& =223.83446 \mathrm{eV}
\end{align*}
$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{18} H_{38}, E_{D_{\text {epp }}}\left(C_{18} H_{38}\right)$, given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{18} H_{38}(\right.\right.$ gas $\left.\left.)=-4.2970 \mathrm{eV}\right)\right)$ [18] and the sum of the enthalpy of the formation of the gaseous carbons $\left(\Delta H_{f}(C(g a s))\right)$ and hydrogen $\left(\Delta H_{f}(H(\right.$ gas $\left.))\right)$ atoms is:

$$
\begin{align*}
E_{D_{\exp }}\left(C_{18} H_{38}\right) & =-\left\{\Delta H_{f}\left(C_{18} H_{38}(\text { gas })\right)-\left[18 \Delta H_{f}(C(\text { gas }))+38 \Delta H_{f}(H(\text { gas }))\right]\right\} \\
& =-\{-4.2970 \mathrm{eV}-[(18) 7.42774 \mathrm{eV}+(38) 2.259353 \mathrm{eV}]\}  \tag{14.667}\\
& =223.85 \mathrm{eV}
\end{align*}
$$

The charge-density of the $C_{18} H_{38}$ molecular orbital (MO) comprising a linear combination of two methyl and sixteen methylene groups is shown in Figure 14.28.

Figure 14.28. $C_{18} H_{38}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and sixteen methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$ bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {octadecane }} 2 s p^{3}$ HOs. (B) Translucent view high-lighting the $C-C$ bond MOs of the charge-density of the $C_{18} H_{38} \mathrm{MO}$. For each $\mathrm{C}-\mathrm{H}$ and the $\mathrm{C}-\mathrm{C}$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {octadecane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {octadecane }} 2 s p^{3}$ HO shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown.

Table 14.1. The calculated and experimental bond parameters of $\mathrm{CO}_{2}, \mathrm{NO}_{2}, \mathrm{CH}_{3} \mathrm{CH}_{3}, \mathrm{CH}_{2} \mathrm{CH}_{2}, \mathrm{CHCH}$, benzene, propane, butane, pentane, hexane, heptane, octane, nonane, decane, undecane, dodecane, and octadecane.

| Parameter | Calculated | Experimental | Ref. for Exp. |
| :---: | :---: | :---: | :---: |
| $\mathrm{CO}_{2}$ Bond Energy | 5.49553 eV | 5.51577 eV | 7 |
| $\mathrm{CO}_{2}$ Bond Length | 1.1616 A | 1.1600 A | 3 |
| $\mathrm{NO}_{2}$ Bond Energy | 3.1532 eV | 3.161 eV | 7 |
| $\mathrm{NO}_{2}$ Bond Length | 1.1872 A | 1.193 A | 3 |
| $\mathrm{NO}_{2}$ Bond Angle | $131.012^{\circ}$ | $134.1^{\circ}$ | 3 |
| $\mathrm{H}_{3} \mathrm{C}-\mathrm{CH}_{3}$ Bond Energy | 3.90245 eV | 3.8969 eV | 7 |
| $\mathrm{H}_{3} \mathrm{C}-\mathrm{CH}_{3}$ Bond Length | 1.53635 A | $1.5351 \AA$ | 3 |
| $\mathrm{H}-\mathrm{CH}_{2} \mathrm{CH}_{3}$ Bond Length | 1.10822 A | 1.0940 § | 3 |
| Ethane $\mathrm{H}-\mathrm{C}-\mathrm{H}$ Bond Angle | $107.44^{\circ}$ | $107.4^{\circ}$ | 8 |
| Ethane $\mathrm{C}-\mathrm{C}-\mathrm{H}$ Bond Angle | $111.44^{\circ}$ | $111.17^{\circ}$ | 3 |

## Chapter 15

## ORGANIC MOLECULAR FUNCTIONAL GROUPS AND MOLECULES

## DERIVATION OF THE GENERAL GEOMETRICAL AND ENERGY EQUATIONS OF ORGANIC CHEMISTRY

Organic molecules comprising an arbitrary number of atoms can be solved using similar principles and procedures as those used to solve alkanes of arbitrary length. Alkanes can be considered to be comprised of the functional groups of $\mathrm{CH}_{3}, \mathrm{CH}_{2}$, and $C-C$. These groups with the corresponding geometrical parameters and energies can be added as a linear sum to give the solution of any straight chain alkane as shown in the Continuous-Chain Alkanes section. Similarly, the geometrical parameters and energies of all functional groups such as alkanes, branched alkanes, alkenes, branched alkenes, alkynes, alkyl fluorides, alkyl chlorides, alkyl bromides, alkyl iodides, alkene halides, primary alcohols, secondary alcohols, tertiary alcohols, ethers, primary amines, secondary amines, tertiary amines, aldehydes, ketones, carboxylic acids, carboxylic esters, amides, N -alkyl amides, $\mathrm{N}, \mathrm{N}$-dialkyl amides, urea, acid halides, acid anhydrides, nitriles, thiols, sulfides, disulfides, sulfoxides, sulfones, sulfites, sulfates, nitro alkanes, nitrites, nitrates, conjugated polyenes, aromatics, heterocyclic aromatics, substituted aromatics, and others can be solved. The functional-group solutions can be made into a linear superposition and sum, respectively, to give the solution of any organic molecule. The solutions of the functional groups can be conveniently obtained by using generalized forms of the geometrical and energy equations. The total bond energies of exemplary organic molecules calculated using the functional group composition and the corresponding energies derived in the following sections compared to the experimental values are given in Tables 15.410.1-15.410.43.

Consider the case wherein at least two atomic orbital hybridize as a linear combination of electrons at the same energy in order to achieve a bond at an energy minimum, and the sharing of electrons between two or more such orbitals to form a MO permits the participating hybridized orbitals to decrease in energy through a decrease in the radius of one or more of the participating orbitals. The force-generalized constant $k^{\prime}$ of a $H_{2}$-type ellipsoidal MO due to the equivalent of two point charges of at the foci is given by:

$$
\begin{equation*}
k^{\prime}=\frac{C_{1} C_{2} 2 e^{2}}{4 \pi \varepsilon_{0}} \tag{15.1}
\end{equation*}
$$

where $C_{1}$ is the fraction of the $H_{2}$-type ellipsoidal MO basis function of a chemical bond of the molecule or molecular ion which is 0.75 (Eq. (13.59)) in the case of $H$ bonding to a central atom and 0.5 (Eq. (14.152)) otherwise, and $C_{2}$ is the factor that results in an equipotential energy match of the participating at least two molecular or atomic orbitals of the chemical bond. From Eqs. (13.58-13.63), the distance from the origin of the MO to each focus $c^{\prime}$ is given by:

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 2 C_{1} C_{2} a}}=\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}} \tag{15.2}
\end{equation*}
$$

The internuclear distance is

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}} \tag{15.3}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal MO $b=c$ is given by:

$$
\begin{equation*}
b=\sqrt{a^{2}-c^{\prime 2}} \tag{15.4}
\end{equation*}
$$

And, the eccentricity, $e$, is

$$
\begin{equation*}
e=\frac{c^{\prime}}{a} \tag{15.5}
\end{equation*}
$$

From Eqs. (11.207-11.212), the potential energy of the two electrons in the central field of the nuclei at the foci is:

$$
\begin{equation*}
V_{e}=n_{1} c_{1} c_{2} \frac{-2 e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}} \tag{15.6}
\end{equation*}
$$

The potential energy of the two nuclei is:

$$
\begin{equation*}
V_{p}=n_{1} \frac{e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}} \tag{15.7}
\end{equation*}
$$

The kinetic energy of the electrons is

$$
\begin{equation*}
T=n_{1} c_{1} c_{2} \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}} \tag{15.8}
\end{equation*}
$$

And, the energy, $V_{m}$, of the magnetic force between the electrons is:

$$
\begin{equation*}
V_{m}=n_{1} c_{1} c_{2} \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}} \tag{15.9}
\end{equation*}
$$

The total energy of the $H_{2}$-type prolate spheroidal MO, $E_{T}\left(\mathrm{H}_{2} \mathrm{MO}\right)$, is given by the sum of the energy terms:

$$
\begin{align*}
& E_{T}\left(\mathrm{H}_{2} M O\right)=V_{e}+T+V_{m}+V_{p}  \tag{15.10}\\
& E_{T}\left(H_{2} M O\right)=-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}-1\right]=-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right] \tag{15.11}
\end{align*}
$$

where $n_{1}$ is the number of equivalent bonds of the MO and applies in the case of functional groups. In the case of independent MOs not in contact with the bonding atoms, the terms based on charge are multiplied by $c_{B O}$, the bond-order factor. It is 1 for a single bond, 4 for an independent double bond as in the case of the $\mathrm{CO}_{2}$ and $\mathrm{NO}_{2}$ molecules, and 9 for an independent triplet bond. Then, the kinetic energy term is multiplied by $c^{\prime}{ }_{B O}$ which is 1 for a single bond, 2 for a double bond, and $9 / 2$ for a triple bond. $c_{1}$ is the fraction of the $H_{2}$-type ellipsoidal MO basis function of an MO which is 0.75 (Eqs. (13.67-13.73)) in the case of $H$ bonding to an unhybridized central atom and 1 otherwise, and $c_{2}$ is the factor that results in an equipotential energy match of the participating MO and at least two atomic orbitals of the chemical bond. Specifically, to meet the equipotential condition and energy matching conditions for the union of the $\mathrm{H}_{2}$-type-ellipsoidal-MO and the HOs or AOs of the bonding atoms, the factor $c_{2}$ of a $H_{2}$-type ellipsoidal MO may given by (i) one, (ii) the ratio of the Coulombic or valence energy of the AO or HO of at least one atom of the bond and 13.605804 eV , the Coulombic energy between the electron and proton of $H$, (iii) the ratio of the valence energy of the AO or HO of one atom and the Coulombic energy of another, (iv) the ratio of the valence energies of the AOs or HOs of two atoms, (v) the ratio of two $c_{2}$ factors corresponding to any of cases (ii)-(iv), and (vi) the product of two different $c_{2}$ factors corresponding to any of the cases (i)-(v). Specific examples of the factor $c_{2}$ of a $H_{2}$-type ellipsoidal MO given in previous sections are:
0.936127 , the ratio of the ionization energy of $N 14.53414 \mathrm{eV}$ and 13.605804 eV , the Coulombic energy between the electron and proton of $H$;

```
0.91771 , the ratio of \(14.82575 \mathrm{eV},-E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)\), and 13.605804 eV ;
    0.87495 , the ratio of \(15.55033 \mathrm{eV},-E_{\text {Coulomb }}\left(C_{\text {ethane }}, 2 s p^{3}\right)\), and 13.605804 eV ;
    0.85252 , the ratio of \(15.95955 \mathrm{eV},-E_{\text {Coulomb }}\left(C_{\text {ethylene }}, 2 s p^{3}\right)\), and 13.605804 eV ;
    0.85252 , the ratio of \(15.95955 \mathrm{eV},-E_{\text {Coulomb }}\left(C_{\text {benzene }}, 2 s p^{3}\right)\), and 13.605804 eV , and
    0.86359 , the ratio of \(15.55033 \mathrm{eV},-E_{\text {Coulomb }}\left(C_{\text {alkane }}, 2 s p^{3}\right)\), and 13.605804 eV .
```

In the generalization of the hybridization of at least two atomic-orbital shells to form a shell of hybrid orbitals, the hybridized shell comprises a linear combination of the electrons of the atomic-orbital shells. The radius of the hybridized shell is calculated from the total Coulombic energy equation by considering that the central field decreases by an integer for each successive electron of the shell and that the total energy of the shell is equal to the total Coulombic energy of the initial AO electrons. The total energy $E_{T}\left(\right.$ atom,$\left.m s p^{3}\right)(m$ is the integer of the valence shell) of the AO electrons and the hybridized shell is given by the sum of energies of successive ions of the atom over the $n$ electrons comprising total electrons of the at least one AO shell.

$$
\begin{equation*}
E_{T}\left(\text { atom }, m s p^{3}\right)=-\sum_{m=1}^{n} I P_{m} \tag{15.12}
\end{equation*}
$$

where $I P_{m}$ is the $m$ th ionization energy (positive) of the atom. The radius $r_{m s p^{3}}$ of the hybridized shell is given by:

$$
\begin{equation*}
r_{m s p^{3}}=\sum_{q=Z-n}^{Z-1} \frac{-(Z-q) e^{2}}{8 \pi \varepsilon_{0} E_{T}\left(\text { atom }, m s p^{3}\right)} \tag{15.13}
\end{equation*}
$$

Then, the Coulombic energy $E_{\text {Coulomb }}\left(\right.$ atom, $\left.m s p^{3}\right)$ of the outer electron of the atom $m s p^{3}$ shell is given by:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(\text { atom, } m s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{m s p^{3}}} \tag{15.14}
\end{equation*}
$$

In the case that during hybridization at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E$ (magnetic) at the initial radius $r$ of the AO electron:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{r^{3}} \tag{15.15}
\end{equation*}
$$

Then, the energy $E\left(\right.$ atom, $\left.m s p^{3}\right)$ of the outer electron of the atom $m s p^{3}$ shell is given by the sum of $E_{\text {Coulomb }}\left(\right.$ atom, $\left.m s p^{3}\right)$ and $E$ (magnetic) :

$$
\begin{equation*}
E\left(\text { atom }, m s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{m s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r^{3}} \tag{15.16}
\end{equation*}
$$

Consider next that the at least two atomic orbitals hybridize as a linear combination of electrons at the same energy in order to achieve a bond at an energy minimum with another atomic orbital or hybridized orbital. As a further generalization of the basis of the stability of the MO, the sharing of electrons between two or more such hybridized orbitals to form a MO permits the participating hybridized orbitals to decrease in energy through a decrease in the radius of one or more of the participating orbitals. In this case, the total energy of the hybridized orbitals is given by the sum of $E$ (atom, $\mathrm{msp}^{3}$ ) and the next energies of successive ions of the atom over the $n$ electrons comprising the total electrons of the at least two initial AO shells. Here, $E\left(\right.$ atom, $\left.m s p^{3}\right)$ is the sum of the first ionization energy of the atom and the hybridization energy. An example of $E\left(\right.$ atom, $\left.m s p^{3}\right)$ for $E\left(C, 2 s p^{3}\right)$ is given in Eq. (14.503) where the sum of the negative of the first ionization energy of $C$, -11.27671 eV , plus the hybridization energy to form the $C 2 s p^{3}$ shell given by Eq. (14.146) is $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$.

Thus, the sharing of electrons between two atom $\mathrm{msp}^{3}$ HOs to form an atom-atom-bond MO permits each participating hybridized orbital to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each atom $\mathrm{msp}^{3} \mathrm{HO}$ donates an excess of $25 \%$ per bond of its electron density to the atom-atom-bond MO to form an energy minimum wherein the atom-atom bond comprises one of a single, double, or triple bond. In each case, the radius of the hybridized shell is calculated from the Coulombic energy equation by considering that the central field decreases by an integer for each successive electron of the shell and the total energy of the shell is equal to the total Coulombic energy of the initial AO electrons plus the hybridization energy. The total energy $E_{T}$ (mol.atom, $m s p^{3}$ ) ( $m$ is the integer of the valence shell) of the HO electrons is given by the sum of energies of successive ions of the atom over the $n$ electrons comprising total electrons of the at least one initial AO shell and the hybridization energy:

$$
\begin{equation*}
E_{T}\left(\text { mol.atom }, m s p^{3}\right)=E\left(\text { atom }, m s p^{3}\right)-\sum_{m=2}^{n} I P_{m} \tag{15.17}
\end{equation*}
$$

where $I P_{m}$ is the $m$ th ionization energy (positive) of the atom and the sum of $-I P_{1}$ plus the hybridization energy is $E\left(\right.$ atom, $\left.m s p^{3}\right)$. Thus, the radius $r_{m s p^{3}}$ of the hybridized shell due to its donation of a total charge $-Q e$ to the corresponding MO is given by:

$$
\begin{equation*}
r_{m s p^{3}}=\left(\sum_{q=Z-n}^{Z-1}(Z-q)-Q\right) \frac{-e^{2}}{8 \pi \varepsilon_{0} E_{T}\left(\text { mol.atom }, m s p^{3}\right)}=\left(\sum_{q=Z-n}^{Z-1}(Z-q)-s(0.25)\right) \frac{-e^{2}}{8 \pi \varepsilon_{0} E_{T}\left(\text { mol.atom }, m s p^{3}\right)} \tag{15.18}
\end{equation*}
$$

where $-e$ is the fundamental electron charge and $s=1,2,3$ for a single, double, and triple bond, respectively. The Coulombic energy $E_{\text {Coulomb }}\left(\right.$ mol.atom, $m s p^{3}$ ) of the outer electron of the atom $m s p^{3}$ shell is given by:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(\text { mol.atom }, m s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{m s p^{3}}} \tag{15.19}
\end{equation*}
$$

In the case that during hybridization at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E$ (magnetic) at the initial radius $r$ of the AO electron given by Eq. (15.15). Then, the energy $E$ (mol.atom, $m s p^{3}$ ) of the outer electron of the atom $m s p^{3}$ shell is given by the sum of $E_{\text {Coulomb }}\left(\right.$ mol.atom, $\left.m s p^{3}\right)$ and $E($ magnetic $)$ :

$$
\begin{equation*}
E\left(\text { mol.atom }, m s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{m s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r^{3}} \tag{15.20}
\end{equation*}
$$

$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3}\right)$, the energy change of each atom msp ${ }^{3}$ shell with the formation of the atom-atom-bond MO is given by: the difference between $E$ (mol.atom, $\left.m s p^{3}\right)$ and $E\left(\right.$ atom, $\left.m s p^{3}\right)$ :

$$
\begin{equation*}
E_{T}\left(\text { atom }- \text { atom }, m s p^{3}\right)=E\left(\text { mol.atom }, m s p^{3}\right)-E\left(\text { atom }, m s p^{3}\right) \tag{15.21}
\end{equation*}
$$

As examples from prior sections, $E_{\text {Coulomb }}\left(\right.$ mol.atom, $\left.m s p^{3}\right)$ is one of:
$E_{\text {Coulomb }}\left(C_{\text {ethylene }}, 2 s p^{3}\right), E_{\text {Coulomb }}\left(C_{\text {ethane }}, 2 s p^{3}\right), E_{\text {Coulomb }}\left(C_{\text {acetylene }}, 2 s p^{3}\right)$, and $E_{\text {Coulomb }}\left(C_{\text {alkane }}, 2 s p^{3}\right)$;
$E_{\text {Coulomb }}\left(\right.$ atom, $\left.m s p^{3}\right)$ is one of $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ and $E_{\text {Coulomb }}\left(C l, 3 s p^{3}\right)$;
$E\left(\right.$ mol.atom, $\left.m s p^{3}\right)$ is one of $E\left(C_{\text {ethylene }}, 2 s p^{3}\right), E\left(C_{\text {ethane }}, 2 s p^{3}\right), E\left(C_{\text {acetylene }}, 2 s p^{3}\right)$ and $E\left(C_{\text {alkane }}, 2 s p^{3}\right)$;
$E\left(\right.$ atom, $\left.m s p^{3}\right)$ is one of $E\left(C, 2 s p^{3}\right)$ and $E\left(C l, 3 s p^{3}\right)$;
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3}\right)$ is one of $E\left(C-C, 2 s p^{3}\right), E\left(C=C, 2 s p^{3}\right)$, and $E\left(C \equiv C, 2 s p^{3}\right)$;
atom $m s p^{3}$ is one of $C 2 s p^{3}$, and $C l 3 s p^{3}$
$E_{T}\left(\operatorname{atom}-\operatorname{atom}\left(s_{1}\right), m s p^{3}\right)$ is $E_{T}\left(C-C, 2 s p^{3}\right)$ and $E_{T}\left(\operatorname{atom}-\operatorname{atom}\left(s_{2}\right), m s p^{3}\right)$ is $E_{T}\left(C=C, 2 s p^{3}\right)$, and
$r_{m s p^{3}}$ is one of $r_{C 2 s p^{3}}, r_{\text {ethane } 2 s p^{3}}, r_{\text {ethylene } 2 s p^{3}}, r_{\text {acetylene } 2 s p^{3}}, r_{\text {alkane2sp }}$, and $r_{C l 3 s p^{3}}$.
In the case of the $C 2 s p^{3} \mathrm{HO}$, the initial parameters (Eqs. (14.142-14.146)) are:

$$
\begin{align*}
& r_{2 s p^{3}}=\sum_{n=2}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 148.25751 \mathrm{eV})}=\frac{10 e^{2}}{8 \pi \varepsilon_{0}(e 148.25751 \mathrm{eV})}=0.91771 a_{0}  \tag{15.22}\\
& E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{2 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.91771 a_{0}}=-14.82575 \mathrm{eV}  \tag{15.23}\\
& E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.84317 a_{0}\right)^{3}}=0.19086 \mathrm{eV}  \tag{15.24}\\
& E\left(C, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=-14.82575 \mathrm{eV}+0.19086 \mathrm{eV}=-14.63489 \mathrm{eV} \tag{15.25}
\end{align*}
$$

In Eq. (15.18),

$$
\begin{equation*}
\sum_{q=Z-n}^{Z-1}(Z-q)=10 \tag{15.26}
\end{equation*}
$$

Eqs. (14.147) and (15.17) gives:

$$
\begin{equation*}
E_{T}\left(\text { mol.atom }, m s p^{3}\right)=E_{T}\left(C_{\text {ethane }}, 2 s p^{3}\right)=-151.61569 \mathrm{eV} \tag{15.27}
\end{equation*}
$$

Using Eqs. (15.18-15.28), the final values of $r_{C 2 s p^{3}}, E_{\text {Coulomb }}\left(C 2 s p^{3}\right)$, and $E\left(C 2 s p^{3}\right)$, and the resulting $E_{T}\left(C^{B O}-C, C 2 s p^{3}\right)$ of the MO due to charge donation from the HO to the MO where $C^{B O}-C$ refers to the bond order of the carbon-carbon bond for different values of the parameter $s$ are given in Table 15.1.

Table 15.1. The final values of $r_{C 2 s p^{3}}, E_{C o u l o m b}\left(C 2 s p^{3}\right)$, and $E\left(C 2 s p^{3}\right)$ and the resulting $E_{T}\left(C^{\underline{B O}} C, C 2 s p^{3}\right)$ of the MO due to charge donation from the HO to the MO where $C^{\frac{B O}{}} C$ refers to the bond order of the carbon-carbon bond.

| MO <br> Bond <br> Order <br> (BO) | $s_{1}$ | $s_{2}$ | $r_{C 2 s p^{3}}\left(a_{0}\right)$ <br> Final | $E_{\text {Coulomb }}\left(C 2 s p^{3}\right)$ <br> $(\mathrm{eV})$ <br> Final | $E\left(C 2 s p^{3}\right)$ <br> $(\mathrm{eV})$ <br> Final | $E_{T}\left(C^{B O}-C, C 2 s p^{3}\right)$ |

In another generalized case of the basis of forming a minimum-energy bond with the constraint that it must meet the energy matching condition for all MOs at all HOs or AOs, the energy $E\left(\right.$ mol.atom, msp ${ }^{3}$ ) of the outer electron of the atom $m s p^{3}$ shell of each bonding atom must be the average of $E\left(\right.$ mol.atom, $\left.m s p^{3}\right)$ for two different values of $s$ :

$$
\begin{equation*}
\left.\left.E\left(\text { mol.atom }, m s p^{3}\right)=\frac{E(\operatorname{mol} . a t o m ~}{}\left(s_{1}\right), m s p^{3}\right)+E\left(\operatorname{mol} . \operatorname{atom}\left(s_{2}\right), m s p^{3}\right)\right) \tag{15.28}
\end{equation*}
$$

In this case, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3}\right)$, the energy change of each atom $m s p^{3}$ shell with the formation of each atom-atom-bond MO, is average for two different values of $s$ :

$$
\begin{equation*}
E_{T}\left(\operatorname{atom}-\operatorname{atom}, m s p^{3}\right)=\frac{E_{T}\left(\operatorname{atom}-\operatorname{atom}\left(s_{1}\right), m s p^{3}\right)+E_{T}\left(\operatorname{atom}-\operatorname{atom}\left(s_{2}\right), m s p^{3}\right)}{2} \tag{15.29}
\end{equation*}
$$

Consider an aromatic molecule such as benzene given in the Benzene Molecule section. Each $C=C$ double bond comprises a linear combination of a factor of 0.75 of four paired electrons (three electrons) from two sets of two $C 2 s p^{3}$ HOs of the participating carbon atoms. Each $C-H$ bond of $C H$ having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of $75 \% H_{2}$-type ellipsoidal MO and $25 \% C 2 s p^{3} \mathrm{HO}$ as given by Eq. (13.439). However, $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3}\right)$ of the $C-H$-bond MO is given by $0.5 E_{T}\left(C=C, 2 s p^{3}\right)$ (Eq. (14.247)) corresponding to one half of a double bond that matches the condition for a single-bond order for $C-H$ that is lowered in energy due to the aromatic character of the bond.

A further general possibility is that a minimum-energy bond is achieved with satisfaction of the potential, kinetic, and orbital energy relationships by the formation of an MO comprising an allowed multiple of a linear combination of $\mathrm{H}_{2}$-type ellipsoidal MOs and corresponding HOs or AOs that contribute a corresponding allowed multiple (e.g. $0.5,0.75,1$ ) of the bond order given in Table 15.1. For example, the alkane MO given in the Continuous-Chain Alkanes section comprises a linear combination of factors of 0.5 of a single bond and 0.5 of a double bond.

Consider a first MO and its HOs comprising a linear combination of bond orders and a second MO that shares a HO with the first. In addition to the mutual HO , the second MO comprises another AO or HO having a single bond order or a mixed bond order. Then, in order for the two MOs to be energy matched, the bond order of the second MO and its HOs or its HO and AO is a linear combination of the terms corresponding to the bond order of the mutual HO and the bond order of the independent HO or AO. Then, in general, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3}\right)$, the energy change of each atom $m s p^{3}$ shell with the formation of each atom-atom-bond MO, is a weighted linear sum for different values of $s$ that matches the energy of the bonded MOs, HOs, and AOs:

$$
\begin{equation*}
E_{T}\left(\operatorname{atom}-\operatorname{atom}, m s p^{3}\right)=\sum_{n=1}^{N} c_{s_{n}} E_{T}\left(\operatorname{atom}-\operatorname{atom}\left(s_{n}\right), m s p^{3}\right) \tag{15.30}
\end{equation*}
$$

where $c_{s_{n}}$ is the multiple of the BO of $s_{n}$. The radius $r_{m s p^{3}}$ of the atom $m s p^{3}$ shell of each bonding atom in given by the Coulombic energy using the initial energy $E_{\text {Coulomb }}\left(\right.$ atom, $\left.m s p^{3}\right)$ and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3}\right)$, the energy change of each atom $m s p^{3}$ shell with the formation of each atom-atom-bond MO:

$$
\begin{equation*}
r_{m s p^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} a_{0}\left(E_{\text {Coulonb }}\left(\text { atom }, m s p^{3}\right)+E_{T}\left(\text { atom }- \text { atom }, m s p^{3}\right)\right)} \tag{15.31}
\end{equation*}
$$

where $E_{C o u l o m b}\left(C 2 s p^{3}\right)=-14.825751 \mathrm{eV}$. The Coulombic energy $E_{\text {Coulomb }}\left(\right.$ mol.atom, msp $\left.{ }^{3}\right)$ of the outer electron of the atom $m s p^{3}$ shell is given by Eq. (15.19). In the case that during hybridization, at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E\left(\right.$ magnetic) (Eq. (15.15)) at the initial radius $r$ of the AO electron. Then, the energy $E$ (mol.atom,msp ${ }^{3}$ ) of the outer electron
of the atom msp ${ }^{3}$ shell is given by the sum of $E_{\text {Coulomb }}$ (mol.atom,msp ${ }^{3}$ ) and E(magnetic) (Eq. (15.20)). $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3}\right)$, the energy change of each atom $m s p^{3}$ shell with the formation of the atom-atom-bond MO is given by the difference between $E$ (mol.atom, $m s p^{3}$ ) and $E\left(\right.$ atom, $\left.m s p^{3}\right)$ given by Eq. (15.21). Using Eq. (15.23) for $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ in Eq. (15.31), the single bond order energies given by Eqs. (15.18-15.27) and shown in Table 15.1, and the linear combination energies (Eqs. (15.28-15.30)), the parameters of linear combinations of bond orders and linear combinations of mixed bond orders are given in Table 15.2.

Table 15.2. The final values of $r_{C 2 s p^{3}}, E_{\text {Coulomb }}\left(C 2 s p^{3}\right)$, and $E\left(C 2 s p^{3}\right)$ and the resulting $E_{T}\left(C^{B O}-C, C 2 s p^{3}\right)$ of the MO comprising a linear combination of $H_{2}$-type ellipsoidal MOs and corresponding HOs of single or mixed bond order where $c_{s_{n}}$ is the multiple of the bond order parameter $E_{T}\left(\right.$ atom $\left.-\operatorname{atom}\left(s_{n}\right), m s p^{3}\right)$ given in Table 15.1.

| MO <br> Bond Order <br> (BO) | $s_{1}$ | $c_{s_{1}}$ | $s_{2}$ | $c_{s_{2}}$ | $s_{3}$ | $c_{s_{3}}$ | $r_{C 2 s p^{3}}\left(a_{0}\right)$ | $E_{\text {Coulomb }}\left(C 2 s p^{3}\right)$ <br> $(\mathrm{eV})$ | $E\left(C 2 s p^{3}\right)$ <br> $(\mathrm{eV})$ | $E_{T}\left(C^{B O}-C, C 2 s p^{3}\right)$ <br> $(\mathrm{eV})$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Final |  |  |  |  |  |  |  |  |  |  |

Consider next the radius of the AO or HO due to the contribution of charge to more than one bond. The energy contribution due to the charge donation at each atom such as carbon superimposes linearly. In general, the radius $r_{\text {mol } 2 s p^{3}}$ of the $C 2 s p^{3} \mathrm{HO}$ of a carbon atom of a given molecule is calculated using Eq. (14.514) by considering $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$, the total energy donation to all bonds with which it participates in bonding. The general equation for the radius is given by:

$$
\begin{equation*}
r_{\text {mol } 2 s p^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0}\left(E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)+\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)\right)}=\frac{e^{2}}{8 \pi \varepsilon_{0}\left(e 14.825751 e V+\sum\left|E_{T_{m o l}}\left(M O, 2 s p^{3}\right)\right|\right)} \tag{15.32}
\end{equation*}
$$

The Coulombic energy $E_{\text {Coulomb }}\left(\right.$ mol.atom, $\left.m s p^{3}\right)$ of the outer electron of the atom msp ${ }^{3}$ shell is given by Eq. (15.19). In the case that during hybridization, at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E$ (magnetic) (Eq. (15.15)) at the initial radius $r$ of the AO electron. Then, the energy $E$ (mol.atom, $m s p^{3}$ ) of the outer electron of the atom $m s p^{3}$ shell is given by the sum of $E_{\text {Coulomb }}\left(\right.$ mol.atom, msp $\left.{ }^{3}\right)$ and $E$ (magnetic) (Eq. (15.20)).

For example, the $C 2 s p^{3} \mathrm{HO}$ of each methyl group of an alkane contributes -0.92918 eV (Eq. (14.513)) to the corresponding single $C-C$ bond; thus, the corresponding $C 2 s p^{3}$ HO radius is given by Eq. (14.514). The $C 2 s p^{3} \mathrm{HO}$ of each methylene group of $C_{n} H_{2 n+2}$ contributes -0.92918 eV to each of the two corresponding $C-C$ bond MOs. Thus, the radius (Eq. (15.32)), the Coulombic energy (Eq. (15.19)), and the energy (Eq. (15.20)) of each alkane methylene group are:

$$
\begin{align*}
& r_{\text {alkane }_{\text {methylene }} 2 s p^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0}\left(E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)+\sum E_{T_{\text {alkane }}}\left(\text { methylene } C-C, 2 s p^{3}\right)\right)}  \tag{15.33}\\
&=\frac{e^{2}}{8 \pi \varepsilon_{0}(e 14.825751 \mathrm{eV}+e 0.92918 \mathrm{eV}+e 0.92918 \mathrm{eV})}=0.81549 a_{0} \\

\end{equation*}
$$

In the determination of the parameters of functional groups, heteroatoms bonding to $C 2 s p^{3}$ HOs to form MOs are energy matched to the $C 2 s p^{3}$ HOs. Thus, the radius and the energy parameters of a bonding heteroatom are given by the same equations as those for $C 2 s p^{3}$ HOs. Using Eqs. (15.15), (15.19-15.20), (15.24), and (15.32) in a generalized fashion, the final values of the radius of the HO or $\mathrm{AO}, r_{\text {Atom. Но.AO }}, E_{\text {Coulomb }}\left(\right.$ mol.atom, $\left.m s p^{3}\right)$, and $E\left(C_{\text {mol }} 2 s p^{3}\right)$ are calculated using $\sum E_{T_{\text {group }}}\left(M O, 2 s p^{3}\right)$, the total energy donation to each bond with which an atom participates in bonding corresponding to the values of $E_{T}\left(C^{B O}-C, C 2 s p^{3}\right)$ of the MO due to charge donation from the AO or HO to the MO given in Tables 15.1 and 15.2.

Table 15.3.A. The final values of $r_{\text {Atom.HOAO }}$, $E_{\text {Coulomb }}\left(\right.$ mol.atom, $\left.m s p^{3}\right)$, and $E\left(C_{m o l} C 2 s p^{3}\right)$ calculated using the values of $E_{T}\left(C^{B O}-C, C 2 s p^{3}\right)$ given in Tables 15.1 and 15.2.

From Eq. (15.18), the general equation for the radius due to a total charge $-Q e$ of an AO or a HO that participates in bonding to form a MO is given by:

$$
\begin{equation*}
r_{m s p^{3}}=\left(\sum_{q=Z-n}^{Z-1}(Z-q)-Q\right) \frac{-e^{2}}{8 \pi \varepsilon_{0} E_{T}\left(\text { mol.atom }, m s p^{3}\right)} \tag{15.36}
\end{equation*}
$$

By equating the radii of Eqs. (15.36) and (15.32), the total charge parameter $Q$ of the AO or HO can be calculated wherein the excess charge is on the MO:

$$
\begin{equation*}
Q=\left(\sum_{q=Z-n}^{Z-1}(Z-q)\right)-\frac{\mid E_{T}\left(\text { mol.atom }, m s p^{3}\right) \mid}{\left(e 14.825751 \mathrm{eV}+\sum\left|E_{T_{\text {mol }}}\left(M O, 2 s p^{3}\right)\right|\right)} \tag{15.37}
\end{equation*}
$$

The modulation of the constant function by the time and spherically harmonic functions as given in Eq. (1.29) time-averages to zero such that the charge density of any HO or AO is determined by the constant function. The charge density $\sigma$ is then given by the fundamental charge $-e$ times the number of electrons $n$ divided by the area of the spherical shell of radius $r_{\text {mol } 2 s p^{3}}$ given by Eq. (15.32):

$$
\begin{equation*}
\sigma=\frac{(n-Q)(-e)}{\frac{4}{3} \pi r_{\text {mol } 2 s p^{3}}^{2}} \tag{15.38}
\end{equation*}
$$

The charge density of an ellipsoidal MO in rectangular coordinates (Eqs. (11.42-11.45)) is:
$\sigma=\frac{q}{4 \pi a b c} \frac{1}{\sqrt{\frac{x^{2}}{a^{4}}+\frac{y^{2}}{b^{4}}+\frac{z^{2}}{c^{4}}}}=\frac{q}{4 \pi a b c} D$
where $D$ is the distance from the origin to the tangent plane. The charge $q$ is given by the fundamental electron charge $-e$ times the sum of parameter $n_{1}$ of Eqs. (15.51) and (15.61) and the charge donation parameter $Q$ (Eq. (15.37)) of each AO or HO to the MO. Thus, the charge density of the MO is given by:

$$
\begin{equation*}
\sigma=\frac{-e\left(n_{1}+Q\right)}{4 \pi a b c} D \tag{15.40}
\end{equation*}
$$

The charge density of the MO that is continuous with the surface of the AO or HO and any radial bisector current resulting from the intersection of two or more MOs as given in the Methane Molecule $\left(\mathrm{CH}_{4}\right)$ section is determined by the current continuity condition. Consider the continuity of the current due to the intersection of an MO with a corresponding AO or HO. The parameters of each point of intersection of each $H_{2}$-type ellipsoidal MO and the corresponding atom AO or HO determined from the polar equation of the ellipse are given by Eqs. (15.80-15.87). The overlap charge $\Delta q$ is given by the total charge of the prolate-spheroidal MO minus the integral of the charge density of the MO over the area between curves of intersection with the AOs or HOs that forms the MO:

$$
\begin{equation*}
\Delta q=-e\left(n_{1}+Q\right)-\int \sigma d A=-e\left(n_{1}+Q\right)\left(1-\int \frac{D}{4 \pi a b c} d A\right) \tag{15.41}
\end{equation*}
$$

The overlap charge of the prolate-spheroidal MO $\Delta q$ is uniformly distributed on the external spherical surface of the AO or HO of radius $r_{\text {mol } 2 s p^{3}}^{3}$ such that the charge density $\sigma$ from Eq. (15.41) is:

$$
\begin{equation*}
\sigma=\frac{\Delta q}{A} \tag{15.42}
\end{equation*}
$$

where $A$ is the external surface area of the AO or HO between the curves of intersection with the MO surface.
At the curves of intersection of two or more MOs where they occur, the current between the AO or HO shell and curves of mutual contact is projected onto and flows in the direction of the radial vector to the surface of the AO or HO shell. This current designated the bisector current $(\mathrm{BC})$ meets the AO or HO surface and does not travel to distances shorter than its radius. Due to symmetry, a radial axis through the AO or HO exists such that current travels from the MOs to the AO or HO along the radial vector in one direction and returns to the MO along the radial vector in the opposite direction from the AO or HO surface to conserve current flow. The MO current onto the bisector currents and the connecting current on the external surface of the AO or HO must be continuously maintained. Given the corresponding constant MO $\omega$ (Eq. (11.24)), the continuity condition requires that the charge density on these surfaces times the area ( $\propto r^{-2}$ ) must be a constant corresponding to constant current, and this current must be matched at the inflow from the MO to the inflow bisector current, the HO or AO external surface, the outflow bisector current, and the return current on the opposite surface of the MO. Thus, $\sigma$ on each surface $s$ having charge $\Delta q_{s}$ is given by Eq. (15.42) wherein $\Delta q=\sum \Delta q_{s}$ and $\Delta q$ is given by Eq. (15.41) with the integral over the MO area between curves of intersection of the MOs. $A$ is surface area corresponding to each $\Delta q_{s}$ of the bisector currents and the external surface of the AO or HO between the curves of intersection of the bisector current with the AO or HO surface. Since the potential of an MO is that of a point charge at infinity (Eq. (11.36)), an asymmetry in the distribution of charge between nonequivalent HOs or AOs of the MO occurs to maintain an energy match of the MO with the bridged orbitals. The charge must redistribute between the spherical orbitals to achieve a corresponding current-density that maintains constant current at the equivalent-energy condition according to the energy-matching factor such as $c_{2}$ or $C_{2}$ of Eqs. (15.51) and (15.61). Since the orbital energy and radius are reciprocally related, the contribution scales as the square of the ratio (over unity) of the energy of the resultant net positively-charged orbital and the initial matched energy of the resultant net negatively-charged orbital of the bond multiplied by the energy-matching factor (e.g. $c_{2}$ or $C_{2}$ ). The partial charges on the HOs or AOs corresponding to the charge contribution are equivalent to point charges centered on the nuclei. Due to symmetry, the bond moment $\mu$ of each functional group is along the internuclear axis and is calculated from the partial changes at the separation distance, the internuclear distance. The dipole moment of a given molecule is then given by the vector sum of the bond moments in the molecule. Thus, the dipole moment is given by taking into account the magnitude and direction of the bond moment of each functional group wherein the functiongroup bond moment stays constant from molecule to molecule and is in the vector direction of the internuclear axis as given in the Bonds and Dipole Moments section.

The angles at which any two prolate spheroidal $A-C$ and $B-C$-bond MOs intersect can be determined using Eq. (13.85) by equating the radii of the elliptic cross sections of the MOs:

$$
\begin{equation*}
\left(a_{1}-c_{1}^{\prime}\right) \frac{1+\frac{c_{1}^{\prime}}{a_{1}}}{1+\frac{c_{1}^{\prime}}{a_{1}} \cos \theta_{1}^{\prime}}=\left(a_{2}-c_{2}^{\prime}\right) \frac{1+\frac{c_{2}^{\prime}}{a_{2}}}{1+\frac{c_{2}^{\prime}}{a_{2}} \cos \theta_{2}^{\prime}} \tag{15.43}
\end{equation*}
$$

and by using the following relationship between the polar angles $\theta_{1}^{\prime}$ and $\theta_{2}^{\prime}$ :

$$
\begin{equation*}
\theta_{\angle A C B}=\theta_{1}^{\prime}+\theta_{2}^{\prime}-360^{\circ} \tag{15.44}
\end{equation*}
$$

where $\theta_{\angle A C B}$ is the bond angle of atoms $A$ and $B$ with central atom $C$. From either angle, the polar radius of intersection can be determined using Eq. (13.85). An example for methane is shown in Eqs. (13.597-13.600). Using these coordinates and the radius of the AO or HO , the limits of the integrals for the determination of the charge densities as well as the regions of each charge density are determined.

The energy of the MO is matched to each of the participating outermost atomic or hybridized orbitals of the bonding atoms wherein the energy match includes the energy contribution due to the AO or HO's donation of charge to the MO. The force constant $k^{\prime}$ (Eq. (15.1)) is used to determine the ellipsoidal parameter $c^{\prime}$ (Eq. (15.2)) of each $H_{2}$-type-ellipsoidal-MO in terms of the central force of the foci. Then, $c^{\prime}$ is substituted into the energy equation (from Eq. (15.11)) which is set equal to $n_{1}$ times the total energy of $H_{2}$ where $n_{1}$ is the number of equivalent bonds of the MO and the energy of $H_{2},-31.63536831 \mathrm{eV}$, Eq. (11.212) is the minimum energy possible for a prolate spheroidal MO. From the energy equation and the relationship between the axes, the dimensions of the MO are solved. The energy equation has the semimajor axis $a$ as its only parameter. The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each MO (Eqs. (15.3-15.5)). The parameter solutions then allow for the component and total energies of the MO to be determined.

The total energy, $E_{T}\left(\mathrm{H}_{2} \mathrm{MO}\right)$, is given by the sum of the energy terms (Eqs. (15.6-15.11)) plus $E_{T}(\mathrm{AO} / \mathrm{HO})$ :

$$
\begin{align*}
E_{T}\left(H_{2} M O\right) & =V_{e}+T+V_{m}+V_{p}+E_{T}(A O / H O)  \tag{15.45}\\
E_{T}\left(H_{2} M O\right) & =-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}-1\right]+E_{T}(A O / H O)  \tag{15.46}\\
& =-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]+E_{T}(A O / H O)
\end{align*}
$$

where $n_{1}$ is the number of equivalent bonds of the MO, $c_{1}$ is the fraction of the $H_{2}$-type ellipsoidal MO basis function of a chemical bond of the group, $c_{2}$ is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of each chemical bond, and $E_{T}(A O / H O)$ is the total energy comprising the difference of the energy $E(A O / H O)$ of at least one atomic or hybrid orbital to which the MO is energy matched and any energy component $\Delta E_{\mathrm{H}_{2} M O}(\mathrm{AO} / \mathrm{HO})$ due to the AO or HO's charge donation to the MO.

$$
\begin{equation*}
E_{T}(A O / H O)=E(A O / H O)-\Delta E_{H_{2} M O}(A O / H O) \tag{15.47}
\end{equation*}
$$

As specific examples given in previous sections, $E_{T}(A O / H O)$ is one from the group of:

$$
\begin{aligned}
& E_{T}(\mathrm{AO} / \mathrm{HO})=E(\text { O2p shell })=-E(\text { ionization; } O)=-13.6181 \mathrm{eV} \text {; } \\
& E_{T}(A O / H O)=E(N 2 p \text { shell })=-E(\text { ionization } ; N)=-14.53414 \mathrm{eV} \text {; } \\
& E_{T}(A O / H O)=E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV} \text {; } \\
& E_{T}(A O / H O)=E_{\text {Coulomb }}\left(C l, 3 s p^{3}\right)=-14.60295 \mathrm{eV} \text {; } \\
& E_{T}(A O / H O)=E(\text { ionization; } C)+E\left(\text { ionization; } C^{+}\right) \text {; } \\
& E_{T}(A O / H O)=E\left(C_{\text {ehanere }}, 2 s p^{3}\right)=-15.35946 \mathrm{eV} \text {; } \\
& E_{T}(A O / H O)=E\left(C_{\text {eltylene }}, 2 s p^{3}\right)-E\left(C_{\text {elhylene }}, 2 s p^{3}\right) \text {; } \\
& E_{T}(A O / H O)=E\left(C, 2 s p^{3}\right)-2 E_{T}\left(C=C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}-(-2.26758 \mathrm{eV}) \text {; } \\
& E_{T}(A O / H O)=E\left(C_{\text {aceetlene }}, 2 s p^{3}\right)-E\left(C_{\text {acetlyene }}, 2 s p^{3}\right)-E\left(C_{\text {aceillene }}, 2 s p^{3}\right)=16.20002 \mathrm{eV} \text {; } \\
& E_{T}(A O / H O)=E\left(C, 2 s p^{3}\right)-2 E_{T}\left(C \equiv C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}-(-3.13026 \mathrm{eV}) \text {; } \\
& E_{T}(A O / H O)=E\left(C_{\text {berzene }}, 2 s p^{3}\right)-E\left(C_{\text {benzene }}, 2 s p^{3}\right) ; \\
& E_{T}(A O / H O)=E\left(C, 2 s p^{3}\right)-E_{T}\left(C=C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}-(-1.13379 \mathrm{eV}) \text {, and } \\
& E_{T}(A O / H O)=E\left(C_{\text {alkane }}, 2 s p^{3}\right)=-15.56407 \mathrm{eV} .
\end{aligned}
$$

To solve the bond parameters and energies, $c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 2 C_{1} C_{2} a}}=\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}$ (Eq. (15.2)) is substituted into $E_{T}\left(H_{2} M O\right)$ to: give

$$
\begin{align*}
E_{T}\left(H_{2} \mu O\right) & =-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}-1\right]+E_{T}(A O / H O) \\
& =-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]+E_{T}(A O / H O)  \tag{15.48}\\
& =-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}{a-\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}-1\right]+E_{T}(A O / H O)
\end{align*}
$$

The total energy is set equal to $E$ (basis energies) which in the most general case is given by the sum of a first integer $n_{1}$ times the total energy of $H_{2}$ minus a second integer $n_{2}$ times the total energy of $H$, minus a third integer $n_{3}$ times the valence energy of $E(A O)$ (e.g. $E(N)=-14.53414 \mathrm{eV}$ ) where the first integer can be $1,2,3 \ldots$, and each of the second and third integers can be 0,1,2,3...

$$
\begin{equation*}
E(\text { basis energies })=n_{1}(-31.63536831 \mathrm{eV})-n_{2}(-13.605804 \mathrm{eV})-n_{3} E(A O) \tag{15.49}
\end{equation*}
$$

In the case that the MO bonds two atoms other than hydrogen, $E$ (basis energies) is $n_{1}$ times the total energy of $H_{2}$ where $n_{1}$ is the number of equivalent bonds of the MO and the energy of $H_{2},-31.63536831 \mathrm{eV}$, Eq. (11.212) is the minimum energy possible for a prolate spheroidal MO:

$$
\begin{equation*}
E(\text { basis energies })=n_{1}(-31.63536831 \mathrm{eV}) \tag{15.50}
\end{equation*}
$$

$E_{T}\left(H_{2} M O\right)$, is set equal to $E$ (basis energies), and the semimajor axis $a$ is solved. Thus, the semimajor axis $a$ is solved from the equation of the form:

$$
\begin{equation*}
-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}{a-\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}-1\right]+E_{T}(A O / H O)=E(\text { basis energies }) \tag{15.51}
\end{equation*}
$$

The distance from the origin of the $H_{2}$-type-ellipsoidal-MO to each focus $c^{\prime}$, the internuclear distance $2 c^{\prime}$, and the length of the semiminor axis of the prolate spheroidal $H_{2}$-type MO $b=c$ are solved from the semimajor axis $a$ using Eqs. (15.2-15.4). Then, the component energies are given by Eqs. (15.6-15.9) and (15.48).

The total energy of the MO of the functional group, $E_{T}(м о)$, is the sum of the total energy of the components comprising the energy contribution of the MO formed between the participating atoms and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} \cdot A O\right)$, the change in the energy of the AOs or HOs upon forming the bond. From Eqs. (15.48-15.49), $E_{T}(м о)$ is:

$$
\begin{equation*}
E_{T}(м о)=E(\text { basis energies })+E_{T}\left(\text { atom }- \text { atom }, m s p^{3} . A O\right) \tag{15.52}
\end{equation*}
$$

During bond formation, the electrons undergo a reentrant oscillatory orbit with vibration of the nuclei, and the corresponding energy $\bar{E}_{\text {osc }}$ is the sum of the Doppler, $\bar{E}_{D}$, and average vibrational kinetic energies, $\bar{E}_{K v i b}$ :

$$
\begin{equation*}
\bar{E}_{o s c}=n_{1}\left(\bar{E}_{D}+\bar{E}_{K v i b}\right)=n_{1}\left(E_{h v} \sqrt{\frac{2 \bar{E}_{K}}{m_{e} c^{2}}}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right) \tag{15.53}
\end{equation*}
$$

where $n_{1}$ is the number of equivalent bonds of the MO, $k$ is the spring constant of the equivalent harmonic oscillator, and $\mu$ is the reduced mass. The angular frequency of the reentrant oscillation in the transition state corresponding to $\bar{E}_{D}$ is determined by the force between the central field and the electrons in the transition state. The force and its derivative are given by:

$$
\begin{equation*}
f(R)=-c_{B O} \frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{0} R^{3}} \tag{15.54}
\end{equation*}
$$

and

$$
\begin{equation*}
f^{\prime}(a)=2 c_{B O} \frac{C_{1 o} C_{2 o} e^{2}}{4 \pi \varepsilon_{0} R^{3}} \tag{15.55}
\end{equation*}
$$

such that the angular frequency of the oscillation in the transition state is given by:

$$
\begin{equation*}
\omega=\sqrt{\frac{\left[\frac{-3}{a} f(a)-f^{\prime}(a)\right]}{m_{e}}}=\sqrt{\frac{k}{m_{e}}}=\sqrt{\frac{c_{B O} \frac{C_{1 o} C_{2 o} e^{2}}{4 \pi \varepsilon_{0} R^{3}}}{m_{e}}} \tag{15.56}
\end{equation*}
$$

where $R$ is the semimajor axis $a$ or the semiminor axis $b$ depending on the eccentricity of the bond that is most representative of the oscillation in the transition state, $c_{B O}$ is the bond-order factor which is 1 for a single bond and when the MO comprises $n_{1}$ equivalent single bonds as in the case of functional groups. $c_{B O}$ is 4 for an independent double bond as in the case of the $\mathrm{CO}_{2}$ and $\mathrm{NO}_{2}$ molecules and 9 for an independent triple bond. $\mathrm{C}_{1 o}$ is the fraction of the $\mathrm{H}_{2}$-type ellipsoidal MO basis function of the oscillatory transition state of a chemical bond of the group, and $C_{2 o}$ is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of the transition state of the chemical bond. Typically, $C_{1 o}=C_{1}$ and $C_{2 o}=C_{2}$. The kinetic energy, $E_{K}$, corresponding to $\bar{E}_{D}$ is given by Planck's equation for functional groups:

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar \sqrt{\frac{\frac{C_{10} C_{2 o} e^{2}}{4 \pi \varepsilon_{0} R^{3}}}{m_{e}}} \tag{15.57}
\end{equation*}
$$

The Doppler energy of the electrons of the reentrant orbit is:

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{m_{e} c^{2}}}=E_{h \nu} \sqrt{\frac{2 \hbar \sqrt{\frac{\frac{C_{10} C_{2 o} e^{2}}{4 \pi \varepsilon_{0} R^{3}}}{m_{e}}}}{m_{e} c^{2}}} \tag{15.58}
\end{equation*}
$$

$\bar{E}_{\text {osc }}$ given by the sum of $\bar{E}_{D}$ and $\bar{E}_{\text {Kvib }}$ is:

$$
\begin{equation*}
\bar{E}_{\text {osc }}(\text { group })=n_{1}\left(\bar{E}_{D}+\bar{E}_{K v i b}\right)=n_{1}\left(E_{h v} \sqrt{\frac{2 \hbar \sqrt{\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{0} R^{3}}} m_{e}}{m_{e} c^{2}}}+E_{v i b}\right) \tag{15.59}
\end{equation*}
$$

$E_{h v}$ of a group having $n_{1}$ bonds is given by $E_{T}(м о) / n_{1}$ such that:

$$
\begin{equation*}
\bar{E}_{o s c}=n_{1}\left(\bar{E}_{D}+\bar{E}_{K v i b}\right)=n_{1}\left(E_{T}(M O) / n_{1} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right) \tag{15.60}
\end{equation*}
$$

$E_{\text {T+оsc }}($ Group $)$ is given by the sum of $E_{T}(м о)$ (Eq. (15.51)) and $\bar{E}_{\text {osc }}$ (Eq. (15.60)).

$$
\begin{align*}
& \left.E_{T+\text { osc }}(\text { Group })=E_{T}(\text { мо })+\bar{E}_{\text {osc }}=\binom{\left(\begin{array}{l}
-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}{a-\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}-1\right.
\end{array}\right]}{+E_{T}(A O / H O)+E_{T}\left(\text { atom }- \text { atom }, m s p^{3} . A O\right)}\right)  \tag{15.61}\\
& \left.=(\text { E(basis energies })+E_{T}\left(\text { atom }- \text { atom, } m s p^{3} . A O\right)\right)\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{0} R^{3}}} \frac{m_{e}}{m_{e} c^{2}}}{}}\right]+n_{1} \frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}
\end{align*}
$$

The total energy of the functional group $E_{T}$ (group) is the sum of the total energy of the components comprising the energy contribution of the MO formed between the participating atoms, E(basis energies), the change in the energy of the AOs or HOs upon forming the bond ( $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ ), the energy of oscillation in the transition state, and the change in magnetic energy with bond formation, $E_{\text {mag }}$. From Eq. (15.61), the total energy of the group $E_{T}($ Group $)$ is:

$$
\begin{equation*}
E_{T}(\text { Group })=\binom{\left(E(\text { basis energies })+E_{T}\left(\text { atom }- \text { atom, } m s p^{3} \cdot A O\right)\right)\left(1+\sqrt{\frac{2 \hbar \sqrt{\frac{\frac{C_{10} C_{2 o} e^{2}}{4 \pi \varepsilon_{0} R^{3}}}{m_{e}}}}{m_{e} c^{2}}}\right]}{+n_{1} \bar{E}_{\text {Kvib }}+E_{m a g}} \tag{15.62}
\end{equation*}
$$

The change in magnetic energy $E_{m a g}$ which arises due to the formation of unpaired electrons in the corresponding fragments relative to the bonded group is given by:

$$
\begin{equation*}
E_{\operatorname{mag}}=c_{3} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r^{3}}=c_{3} \frac{8 \pi \mu_{0} \mu_{B}^{2}}{r^{3}} \tag{15.63}
\end{equation*}
$$

where $r$ is the radius of the atom that reacts to form the bond and $c_{3}$ is the number of electron pairs.

$$
\begin{equation*}
E_{T}(\text { Group })=\binom{\left(E(\text { basis energies })+E_{T}\left(\text { atom }- \text { atom, } m s p^{3} \cdot A O\right)\right)\left(1+\sqrt{\frac{2 \hbar \sqrt{\frac{\frac{C_{10} C_{2 o} e^{2}}{4 \pi \varepsilon_{0} R^{3}}}{m_{e}}}}{m_{e} c^{2}}}\right]}{+n_{1} \bar{E}_{K v i b}+c_{3} \frac{8 \pi \mu_{0} \mu_{B}^{2}}{r^{3}}} \tag{15.64}
\end{equation*}
$$

The total bond energy of the group $E_{D}($ Group $)$ is the negative difference of the total energy of the group (Eq. (15.64)) and the total energy of the two starting orbitals given by the sum of $c_{4} E_{\text {initial }}\left(c_{4} A O / H O\right)$ and $c_{5} E_{\text {initial }}\left(c_{5} A O / H O\right)$ :

$$
E_{D}(\text { Group })=-\binom{\left.(\text { (basis energies })+E_{T}\left(\text { atom }- \text { atom, } m s p^{3} \cdot A O\right)\right)\left[\begin{array}{l}
\frac{2 \hbar \sqrt{\frac{\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{0} R^{3}}}{m_{e}}}}{m_{e} c^{2}} \tag{15.65}
\end{array}\right]}{+n_{1} \bar{E}_{\text {Kvib }}+c_{3} \frac{8 \pi \mu_{0} \mu_{B}^{2}}{r^{3}}-\left(c_{4} E_{\text {initial }}\left(c_{4} A O / H O\right)+c_{5} E_{\text {initial }}\left(c_{5} A O / H O\right)\right)}
$$

In the case of organic molecules, the atoms of the functional groups are energy matched to the $C 2 s p^{3} \mathrm{HO}$ such that:

$$
\begin{equation*}
E(A O / H O)=-14.63489 \mathrm{eV} \tag{15.66}
\end{equation*}
$$

For examples of $E_{\text {mag }}$ from previous sections:

$$
\begin{align*}
& E_{\text {mag }}\left(C 2 s p^{3}\right)=c_{3} \frac{8 \pi \mu_{0} \mu_{B}^{2}}{r^{3}}=c_{3} \frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.91771 a_{0}\right)^{3}}=c_{3} 0.14803 \mathrm{eV}  \tag{15.67}\\
& E_{\text {mag }}(O 2 p)=c_{3} \frac{8 \pi \mu_{0} \mu_{B}^{2}}{r^{3}}=c_{3} \frac{8 \pi \mu_{0} \mu_{B}^{2}}{a_{0}^{3}}=c_{3} 0.11441 \mathrm{eV}  \tag{15.68}\\
& E_{\text {mag }}(N 2 p)=c_{3} \frac{8 \pi \mu_{0} \mu_{B}^{2}}{r^{3}}=c_{3} \frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.93084 a_{0}\right)^{3}}=c_{3} 0.14185 \mathrm{eV} \tag{15.69}
\end{align*}
$$

In the general case of the solution of an organic functional group, the geometric bond parameters are solved from the semimajor axis and the relationships between the parameters by first using Eq. (15.51) to arrive at $a$. Then, the remaining parameters are determined using Eqs. (15.1-15.5). Next, the energies are given by Eqs. (15.61-15.68). To meet the equipotential condition for the union of the $H_{2}$-type-ellipsoidal-MO and the HO or AO of the atom of a functional group, the factor $c_{2}$ of a $H_{2}$-type ellipsoidal MO in principal Eqs. (15.51) and (15.61) may given by:
(i) one:

$$
\begin{equation*}
c_{2}=1 \tag{15.70}
\end{equation*}
$$

(ii) the ratio that is less than one of 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264), and the magnitude of the Coulombic energy of the participating AO or HO of the atom, $E_{\text {Coulomb }}\left(\right.$ MO.atom, $\left.\mathrm{msp}^{3}\right)$ given by Eqs. (15.19) and (15.31-15.32). For $\mid E_{\text {Coulomb }}\left(\right.$ MO.atom, $\left.\mathrm{msp}^{3}\right) \mid>13.605804 \mathrm{eV}$ :

$$
\begin{align*}
& c_{2}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} r_{A-B ~ A o r s s p^{3}}}}=\frac{13.605804 \mathrm{eV}}{\mid E_{\text {Coulomb }}\left(\text { MO.atom }, \mathrm{msp}^{3}\right) \mid}  \tag{15.71}\\
& \text { For } \mid E_{\text {Coulomb }}\left(\text { MO.atom, } \mathrm{msp}^{3}\right) \mid<13.605804 \mathrm{eV}: \\
& c_{2}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} r_{A-B ~ A o r s s p^{3}}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}=\frac{\mid E_{\text {Coulomb }}\left(\text { MO.atom }, \mathrm{msp}^{3}\right) \mid}{13.605804 \mathrm{eV}} \tag{15.72}
\end{align*}
$$

(iii) the ratio that is less than one of 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264), and the magnitude of the valence energy, $E$ (valence), of the participating AO or HO of the atom where $E$ (valence) is the ionization energy or $E$ (MO.atom, $m s p^{3}$ ) given by Eqs. (15.20) and (15.31-15.32). For $\mid E($ valence $) \mid>13.605804 \mathrm{eV}$ :
$c_{2}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} r_{A-B ~ A o r B s p^{3}}}}=\frac{13.605804 \mathrm{eV}}{\mid E(\text { valence }) \mid}$
For $\mid E$ (valence) $\mid<13.605804 \mathrm{eV}$ :
$c_{2}=\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} r_{A-B ~ A o r B s p^{3}}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}=\frac{\mid E(\text { valence }) \mid}{13.605804 \mathrm{eV}}$
(iv) the ratio that is less than one of the magnitude of the Coulombic energy of the participating AO or HO of a first atom, $E_{\text {Coulomb }}$ (MO.atom, msp ${ }^{3}$ ) given by Eqs. (15.19) and (15.31-15.32), and the magnitude of the valence energy, $E$ (valence), of the participating AO or HO of a second atom to which the first is energy matched where $E$ (valence) is the ionization energy or $E\left(M O . a t o m, m s p^{3}\right)$ given by Eqs. (15.20) and (15.31-15.32). For $\mid E_{\text {Coulomb }}\left(\right.$ MO.atom, msp $\left.^{3}\right) \mid>E($ valence $)$ :
$c_{2}=\frac{\mid E(\text { valence }) \mid}{\mid E_{\text {Coulomb }}\left(\text { MO.atom }, \text { msp }^{3}\right) \mid}$
For $\mid E_{\text {Coulomb }}$ (MO.atom, msp $\left.{ }^{3}\right) \mid<E$ (valence) :
$c_{2}=\frac{\mid E_{\text {Coulomb }}\left(\text { MO.atom }, \text { msp }^{3}\right) \mid}{\mid E(\text { valence }) \mid}$
(v) the ratio of the magnitude of the valence-level energies, $E_{n}$ (valence), of the AO or HO of the nth participating atom of two that are energy matched where $E$ (valence) is the ionization energy or $E$ (MO.atom,msp ${ }^{3}$ ) given by Eqs. (15.20) and (15.31-15.32):
$c_{2}=\frac{E_{1}(\text { valence })}{E_{2}(\text { valence })}$
(vi) the factor that is the ratio of the hybridization factor $c_{2}(1)$ of the valence AO or HO of a first atom and the hybridization factor $c_{2}(2)$ of the valence AO or HO of a second atom to which the first is energy matched where $c_{2}(n)$ is given by Eqs. (15.71-15.77); alternatively $c_{2}$ is the hybridization factor $c_{2}(1)$ of the valence AOs or HOs a first pair of atoms and the hybridization factor $c_{2}(2)$ of the valence AO or HO a third atom or second pair to which the first two are energy matched:

$$
\begin{equation*}
c_{2}=\frac{c_{2}(1)}{c_{2}(2)} \tag{15.78}
\end{equation*}
$$

(vii) the factor that is the product of the hybridization factor $c_{2}(1)$ of the valence AO or HO of a first atom and the hybridization factor $c_{2}(2)$ of the valence AO or HO of a second atom to which the first is energy matched where $c_{2}(n)$ is given by Eqs. (15.71-15.78); alternatively $c_{2}$ is the hybridization factor $c_{2}(1)$ of the valence AOs or HOs a first pair of atoms and the hybridization factor $c_{2}(2)$ of the valence AO or HO a third atom or second pair to which the first two are energy matched:

$$
\begin{equation*}
c_{2}=c_{2}(1) c_{2}(2) \tag{15.79}
\end{equation*}
$$

The hybridization factor $c_{2}$ corresponds to the force constant $k$ (Eqs. (11.65) and (13.58)). In the case that the valence or Coulombic energy of the AO or HO is less than 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264), then $C_{2}$ corresponding to $k^{\prime}$ (Eq. (15.1)) is given by Eqs. (15.71-15.79).

Specific examples of the factors $c_{2}$ and $C_{2}$ of a $H_{2}$-type ellipsoidal MO of Eq. (15.60) given in following sections are:
$c_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to $\left.F\right)=\frac{E\left(C, 2 s p^{3}\right)}{E(F)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-14.63489 \mathrm{eV}}{-17.42282 \mathrm{eV}}(0.91771)=0.77087$;
$C_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to Cl$)=\frac{E(\mathrm{Cl})}{E\left(\mathrm{C}, 2 s p^{3}\right)} c_{2}\left(\mathrm{C} 2 s p^{3} \mathrm{HO}\right)=\frac{-12.96764 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.81317$;
$C_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to Br$)=\frac{E(B r)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-11.81381 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.74081$;
$C_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to I$)=\frac{E(I)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-10.45126 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.65537$;
$c_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to O$)=\frac{E(O)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-13.61806 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.85395$;
$c_{2}\left(H\right.$ to $\left.1^{\circ} N\right)=\frac{E(N)}{E\left(C, 2 s p^{3}\right)}=\frac{-14.53414 \mathrm{eV}}{-15.35946 \mathrm{eV}}=0.94627$;
$c_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to N$)=\frac{E(N)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-14.53414 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.91140$;
$c_{2}\left(H\right.$ to $\left.2^{\circ} N\right)=\frac{E(N)}{E\left(C, 2 s p^{3}\right)}=\frac{-14.53414 \mathrm{eV}}{-15.56407 \mathrm{eV}}=0.93383$;
$C_{2}(S 3 p$ to $H)=\frac{E(S, 3 p)}{E(H)}=\frac{-10.36001 \mathrm{eV}}{-13.60580 \mathrm{eV}}=0.76144$;
$C_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to S$)=\frac{E(S)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-10.36001 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.64965$;
$c_{2}\left(O\right.$ to $S 3 s p^{3}$ to $\left.C 2 s p^{3} \mathrm{HO}\right)=\frac{E(O)}{E(S)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-13.61806 \mathrm{eV}}{-10.36001 \mathrm{eV}}(0.91771)=1.20632$;
$c_{2}\left(S 3 s p^{3}\right)=\frac{E_{\text {Coulomb }}\left(S 3 s p^{3}\right)}{E(H)}=\frac{-11.57099 \mathrm{eV}}{-13.60580 \mathrm{eV}}=0.85045$;
$C_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to $\left.S 3 s p^{3}\right)=\frac{E\left(S 3 s p^{3}\right)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(S 3 s p^{3}\right)=\frac{-11.52126 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.85045)=0.66951$;
$C_{2}\left(S 3 s p^{3}\right.$ to $O$ to $\left.C 2 s p^{3} H O\right)=\frac{E\left(S, 3 s p^{3}\right)}{E(O, 2 p)} c_{2}\left(C 2 s p^{3} H O\right)=\frac{-11.52126 \mathrm{eV}}{-13.61806 \mathrm{eV}}(0.91771)=0.77641$;
$c_{2}\left(O\right.$ to $N 2 p$ to $\left.C 2 s p^{3} \mathrm{HO}\right)=\frac{E(O)}{E(N)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-13.61806 \mathrm{eV}}{-14.53414 \mathrm{eV}}(0.91771)=0.85987$;

$$
\begin{aligned}
& c_{2}(N 2 p \text { to } O 2 p)=\frac{c_{2}\left(C 2 s p^{3} H O \text { to } N\right)}{c_{2}\left(C 2 s p^{3} H O \text { to } O\right)}=\frac{0.91140}{0.85395}=1.06727 ; \\
& C_{2}\left(\text { benzene } C 2 s p^{3} H O\right)=c_{2}\left(\text { benzene } 2 s p^{3} H O\right)=\frac{13.605804 \mathrm{eV}}{15.95955 \mathrm{eV}}=0.85252 ; \\
& c_{2}\left(\text { arylC } 2 s p^{3} H O \text { to } O\right)=\frac{E(O)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(\text { arylC } 2 \mathrm{sp} p^{3} \mathrm{HO}\right)=\frac{-13.61806 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.85252)=0.79329 ; \\
& c_{2}(\mathrm{H} \text { to aniline } N)=\frac{E(N)}{E\left(C, 2 s p^{3}\right)}=\frac{-14.53414 \mathrm{eV}}{-15.76868 \mathrm{eV}}=0.92171 ; \\
& c_{2}\left(\text { arylC } 2 s p^{3} H O \text { to } N\right)=\frac{E(N)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(\text { arylC } 2 s p^{3} \mathrm{HO}\right)=\frac{-14.53414 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.85252)=0.84665, \text { and } \\
& C_{2}\left(S 3 p \text { to aryl -type } C 2 s p^{3} \mathrm{HO}\right)=\frac{E(S, 3 p)}{E\left(C, 2 s p^{3}\right)}=\frac{-10.36001 \mathrm{eV}}{-15.76868 \mathrm{eV}}=0.65700 .
\end{aligned}
$$

## MO INTERCEPT ANGLES AND DISTANCES

Consider the general case of Eqs. (13.84-13.95), wherein the nucleus of a $B$ atom and the nucleus of a $A$ atom comprise the foci of each $H_{2}$-type ellipsoidal MO of an $A-B$ bond. The parameters of the point of intersection of each $H_{2}$-type ellipsoidal MO and the $A$-atom AO are determined from the polar equation of the ellipse:

$$
\begin{equation*}
r=r_{0} \frac{1+e}{1+e \cos \theta^{\prime}} \tag{15.80}
\end{equation*}
$$

The radius of the $A$ shell is $r_{A}$, and the polar radial coordinate of the ellipse and the radius of the $A$ shell are equal at the point of intersection such that:

$$
\begin{equation*}
r_{A}=\left(a-c^{\prime}\right) \frac{1+\frac{c^{\prime}}{a}}{1+\frac{c^{\prime}}{a} \cos \theta^{\prime}} \tag{15.81}
\end{equation*}
$$

The polar angle $\theta^{\prime}$ at the intersection point is given by:

$$
\begin{equation*}
\theta^{\prime}=\cos ^{-1}\left(\frac{a}{c^{\prime}}\left(\left(a-c^{\prime}\right) \frac{1+\frac{c^{\prime}}{a}}{r_{A}}-1\right)\right) \tag{15.82}
\end{equation*}
$$

Then, the angle $\theta_{A A O}$ the radial vector of the $A$ AO makes with the internuclear axis is:

$$
\begin{equation*}
\theta_{A A O}=180^{\circ}-\theta^{\prime} \tag{15.83}
\end{equation*}
$$

The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{H_{2} M O}$ satisfies the following relationship:

$$
\begin{equation*}
r_{A} \sin \theta_{A A O}=b \sin \theta_{H_{2} M O} \tag{15.84}
\end{equation*}
$$

such that

$$
\begin{equation*}
\theta_{H_{2} M O}=\sin ^{-1} \frac{r_{a} \sin \theta_{A A O}}{b} \tag{15.85}
\end{equation*}
$$

The distance $d_{\mathrm{H}_{2} \mathrm{MO}}$ along the internuclear axis from the origin of $\mathrm{H}_{2}$-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{\mathrm{H}_{2} \mathrm{MO}}=a \cos \theta_{\mathrm{H}_{2} \mathrm{MO}} \tag{15.86}
\end{equation*}
$$

The distance $d_{A A O}$ along the internuclear axis from the origin of the $A$ atom to the point of intersection of the orbitals is given by:

$$
\begin{equation*}
d_{A A O}=c^{\prime}-d_{H_{2} M O} \tag{15.87}
\end{equation*}
$$

## BOND ANGLES

Further consider an $A C B$ MO comprising a linear combination of $C-A$-bond and $C-B$-bond MOs where $C$ is the general central atom. A bond is also possible between the $A$ and $B$ atoms of the $C-A$ and $C-B$ bonds. Such $A-B$ bonding would decrease the $C-A$ and $C-B$ bond strengths since electron density would be shifted from the latter bonds to the former bond. Thus, the $\angle A C B$ bond angle is determined by the condition that the total energy of the $H_{2}$-type ellipsoidal MO between the
terminal $A$ and $B$ atoms is zero. The force constant $k^{\prime}$ of a $H_{2}$-type ellipsoidal MO due to the equivalent of two point charges of at the foci is given by:

$$
\begin{equation*}
k^{\prime}=\frac{C_{1} C_{2} 2 e^{2}}{4 \pi \varepsilon_{0}} \tag{15.88}
\end{equation*}
$$

where $C_{1}$ is the fraction of the $H_{2}$-type ellipsoidal MO basis function of a chemical bond of the molecule which is 0.75 (Eq. (13.59)) for a terminal $A-H$ ( $A$ is $H$ or other atom) and 1 otherwise and $C_{2}$ is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of the chemical bond and is equal to the corresponding factor of Eqs. (15.51) and (15.61). The distance from the origin of the MO to each focus $c^{\prime}$ of the $A-B$ ellipsoidal MO is given by:

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 2 C_{1} C_{2} a}}=\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}} \tag{15.89}
\end{equation*}
$$

The internuclear distance is:

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}} \tag{15.90}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal $A-B$ MO $b=c$ is given by Eq. (15.4).
The component energies and the total energy, $E_{T}\left(H_{2} M O\right)$, of the $A-B$ bond are given by the energy equations (Eqs. (11.207-11.212), (11.213-11.217), and (11.239)) of $H_{2}$ except that the terms based on charge are multiplied by $c_{B O}$, the bondorder factor which is 1 for a single bond and when the MO comprises $n_{1}$ equivalent single bonds as in the case of functional groups. $c_{B O}$ is 4 for an independent double bond as in the case of the $\mathrm{CO}_{2}$ and $\mathrm{NO}_{2}$ molecules. The kinetic energy term is multiplied by ${c^{\prime}}^{\prime}$ о which is 1 for a single bond, 2 for a double bond, and $9 / 2$ for a triple bond. The electron energy terms are multiplied by $c_{1}$, the fraction of the $H_{2}$-type ellipsoidal MO basis function of a terminal chemical bond, which is 0.75 (Eq. (13.233)) for a terminal $A-H$ ( $A$ is $H$ or other atom) and 1 otherwise. The electron energy terms are further multiplied by $c_{2}^{\prime}$, the hybridization or energy-matching factor that results in an equipotential energy match of the participating at least two atomic orbitals of each terminal bond. Furthermore, when $A-B$ comprises atoms other than $H, E_{T}\left(\right.$ atom-atom, msp $\left.{ }^{3} \cdot A O\right)$, the energy component due to the AO or HO's charge donation to the terminal MO, is added to the other energy terms to give $E_{T}\left(\mathrm{H}_{2} M O\right)$ :

$$
\begin{equation*}
E_{T}\left(H_{2} M O\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[c_{1} c_{2}^{\prime}\left(2 c_{B O}-c_{B O}^{\prime} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]+E_{T}\left(\text { atom }- \text { atom }, m s p^{3} . A O\right) \tag{15.91}
\end{equation*}
$$

The radiation reaction force in the case of the vibration of $A-B$ in the transition state corresponds to the Doppler energy, $E_{D}$, given by Eq. (11.181) that is dependent on the motion of the electrons and the nuclei. The total energy that includes the radiation reaction of the $A-B \mathrm{MO}$ is given by the sum of $E_{T}\left(H_{2} M O\right)$ (Eq. (15.91)) and $\bar{E}_{\text {osc }}$ given by Eqs. (11.213-11.220), (11.231-11.236), and (11.239-11.240). Thus, the total energy $E_{T}(A-B)$ of the $A-B$ MO including the Doppler term is:

$$
E_{T}(A-B)=\left[\begin{array}{l}
\left(\frac{-e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[c_{1} c_{2}^{\prime}\left(2 c_{B O}-c^{\prime}{ }_{B O} \frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]+E_{T}\left(\text { atom-atom, msp }{ }^{3} \cdot A O\right)\right)  \tag{15.92}\\
{\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{c_{B O} \frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{0} a^{3}}}{m_{e}}}}{m_{e} c^{2}}}\right]+\frac{1}{2} \hbar \sqrt{\frac{c_{B O} \frac{c_{1} c_{2}^{\prime} e^{2}}{8 \pi \varepsilon_{0} a^{3}}-\frac{c_{B O} e^{2}}{8 \pi \varepsilon_{0}\left(a+c^{\prime}\right)^{3}}}{\mu}}}
\end{array}\right]
$$

where $C_{10}$ is the fraction of the $H_{2}$-type ellipsoidal MO basis function of the oscillatory transition state of the $A-B$ bond which is 0.75 (Eq. (13.233)) in the case of $H$ bonding to a central atom and 1 otherwise, $C_{20}$ is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of the transition state of the chemical bond, and $\mu=\frac{m_{1} m_{2}}{m_{1}+m_{2}}$ is the reduced mass of the nuclei given by Eq. (11.154). To match the boundary condition that the total energy of the $A-B$ ellipsoidal MO is zero, $E_{T}(A-B)$ given by Eq. (15.92) is set equal to zero. Substitution of Eq. (15.90) into Eq. (15.92) gives:

$$
\left.\left.0=\left[\begin{array}{l}
\left(\frac { - e ^ { 2 } } { 8 \pi \varepsilon _ { 0 } \sqrt { \frac { a a _ { 0 } } { 2 C _ { 1 } C _ { 2 } } } } \left[c_{1} c_{2}^{\prime}\left(2 c_{B O}-c^{\prime}{ }_{B O} \frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}{a-\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}-1\right.\right. \tag{15.93}
\end{array}\right]+E_{T}\left(\text { atom-atom,msp}{ }^{3} \cdot A O\right)\right)\right]
$$

The vibrational energy-term of Eq. (15.93) is determined by the forces between the central field and the electrons and those between the nuclei (Eqs. (11.141-11.145)). The electron-central-field force and its derivative are given by:

$$
\begin{equation*}
f(a)=-c_{B O} \frac{c_{1} c_{2}^{\prime} e^{2}}{4 \pi \varepsilon_{0} a^{3}} \tag{15.94}
\end{equation*}
$$

and

$$
\begin{equation*}
f^{\prime}(a)=2 c_{B O} \frac{c_{1} c_{2}^{\prime} e^{2}}{4 \pi \varepsilon_{0} a^{3}} \tag{15.95}
\end{equation*}
$$

The nuclear repulsion force and its derivative are given by:

$$
\begin{equation*}
f\left(a+c^{\prime}\right)=\frac{e^{2}}{8 \pi \varepsilon_{0}\left(a+c^{\prime}\right)^{2}} \tag{15.96}
\end{equation*}
$$

and

$$
\begin{equation*}
f^{\prime}\left(a+c^{\prime}\right)=-\frac{e^{2}}{4 \pi \varepsilon_{0}\left(a+c^{\prime}\right)^{3}} \tag{15.97}
\end{equation*}
$$

such that the angular frequency of the oscillation is given by:

$$
\begin{equation*}
\omega=\sqrt{\frac{\left[\frac{-3}{a} f(a)-f^{\prime}(a)\right]}{\mu}}=\sqrt{\frac{k}{m_{e}}}=\sqrt{\frac{c_{B O} \frac{c_{1} c_{2}^{\prime} e^{2}}{4 \pi \varepsilon_{0} a^{3}}-\frac{e^{2}}{8 \pi \varepsilon_{0}\left(a+c^{\prime}\right)^{2}}}{\mu}} \tag{15.98}
\end{equation*}
$$

Since both terms of $\bar{E}_{o s c}=\bar{E}_{D}+\bar{E}_{K v i b}$ are small due to the large values of $a$ and $c^{\prime}$, to very good approximation, a convenient form of Eq. (15.93) which is evaluated to determine the bond angles of functional groups is given by:

$$
\left.\left.0=\left[\begin{array}{l}
{\left[\frac { - e ^ { 2 } } { 8 \pi \varepsilon _ { 0 } \sqrt { \frac { a a _ { 0 } } { 2 C _ { 1 } C _ { 2 } } } } \left[c_{1} c_{2}^{\prime}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}{a-\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}-1\right.\right.} \tag{15.99}
\end{array}\right]+E_{T}\left(\text { atom-atom, msp }{ }^{3} \cdot A O\right)\right)\right]
$$

From the energy relationship given by Eq. (15.99) and the relationship between the axes given by Eqs. (15.2-15.5), the dimensions of the $A-B$ MO can be solved. The most convenient way to solve Eq. (15.99) is by the reiterative technique using a computer.

A factor $c_{2}$ of a given atom in the determination of $c_{2}^{\prime}$ for calculating the zero of the total $A-B$ bond energy is typically given by Eqs. (15.71-15.74). In the case of a $H-H$ terminal bond of an alkyl or alkenyl group, $c_{2}^{\prime}$ is typically the ratio of $c_{2}$ of Eq. (15.71) for the $H-H$ bond which is one and $c_{2}$ of the carbon of the corresponding $C-H$ bond:

$$
\begin{equation*}
c_{2}^{\prime}=\frac{1}{c_{2}\left(C 2 s p^{3}\right)}=\frac{E_{\text {Coulomb }}\left(C-H C 2 s p^{3}\right)}{13.605804 \mathrm{eV}} \tag{15.100}
\end{equation*}
$$

In the case of the determination of the bond angle of the $A C H$ MO comprising a linear combination of $C-A$-bond and $C-H-$ bond MOs where $A$ and $C$ are general, $C$ is the central atom, and $c_{2}$ for an atom is given by Eqs. (15.71-15.79), $c_{2}^{\prime}$ of the
$A-H$ terminal bond is typically the ratio of $c_{2}$ of the $A$ atom for the $A-H$ terminal bond and $c_{2}$ of the $C$ atom of the corresponding $C-H$ bond:

$$
\begin{equation*}
c_{2}^{\prime}=\frac{c_{2}\left(A(A-H) m s p^{3}\right)}{c_{2}\left(C(C-H) m s p^{3}\right)} \tag{15.101}
\end{equation*}
$$

In the case of the determination of the bond angle of the COH MO of an alcohol comprising a linear combination of $\mathrm{C}-\mathrm{O}$ bond and $O-H$-bond MOs where $C, O$, and $H$ are carbon, oxygen, and hydrogen, respectively, $c_{2}^{\prime}$ of the $C-H$ terminal bond is typically 0.91771 since the oxygen and hydrogen atoms are at the Coulomb potential of a proton and an electron (Eqs. (1.257) and (10.162), respectively) that is energy matched to the $C 2 s p^{3} \mathrm{HO}$.

In the determination of the hybridization factor $c_{2}^{\prime}$ of Eq. (15.99) from Eqs. (15.71-15.79), the Coulombic energy, $E_{\text {Coulomb }}\left(\right.$ MO.atom, $\left.m s p^{3}\right)$, or the energy, $E\left(\right.$ MO.atom, $\left.m s p^{3}\right)$, the radius $r_{A-B A o r s p^{3}}$ of the $A$ or $B \mathrm{AO}$ or HO of the heteroatom of the $A-B$ terminal bond MO such as the $C 2 s p^{3} \mathrm{HO}$ of a terminal $C-C$ bond is calculated using Eq. (15.32) by considering $\sum E_{T_{\text {mol }}}\left(M O, 2 s p^{3}\right)$, the total energy donation to each bond with which it participates in bonding as it forms the terminal bond. The Coulombic energy $E_{\text {Coulomb }}\left(M O . a t o m, m s p^{3}\right)$ of the outer electron of the atom msp ${ }^{3}$ shell is given by Eq. (15.19). In the case that during hybridization, at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E$ (magnetic) (Eq. (15.15)) at the initial radius $r$ of the AO electron. Then, the energy $E\left(\right.$ MO.atom, $\left.m s p^{3}\right)$ of the outer electron of the atom $m s p^{3}$ shell is given by the sum of $E_{\text {Coulomb }}\left(\right.$ MO.atom, msp $\left.{ }^{3}\right)$ and $E$ (magnetic) (Eq. (15.20)).

In the specific case of the terminal bonding of two carbon atoms, the $c_{2}$ factor of each carbon given by Eq. (15.71) is determined using the Coulombic energy $E_{\text {Coulomb }}\left(C-C C 2 s p^{3}\right)$ of the outer electron of the $C 2 s p^{3}$ shell given by Eq. (15.19) with the radius $r_{C-C C 2 s p^{3}}$ of each $C 2 s p^{3} \mathrm{HO}$ of the terminal $C-C$ bond calculated using Eq. (15.32) by considering $\sum E_{T_{m o l}}\left(M O, 2 s p^{3}\right)$, the total energy donation to each bond with which it participates in bonding as it forms the terminal bond including the contribution of the methylene energy, 0.92918 eV (Eq. (14.513)), corresponding to the terminal $C-C$ bond. The corresponding $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ in Eq. (15.99) is $E_{T}\left(C-C C 2 s p^{3}\right)=-1.85836 \mathrm{eV}$.

In the case that the terminal atoms are carbon or other heteroatoms, the terminal bond comprises a linear combination of the HOs or AOs; thus, $c_{2}^{\prime}$ is the average of the hybridization factors of the participating atoms corresponding to the normalized linear sum:

$$
\begin{equation*}
c_{2}^{\prime}=\frac{1}{2}\left(c_{2}^{\prime}(\text { atom } 1)+c_{2}^{\prime}(\text { atom } 2)\right) \tag{15.102}
\end{equation*}
$$

In the exemplary cases of $C-C, O-O$, and $N-N$ where $C$ is carbon:

$$
\begin{align*}
c_{2}^{\prime} & =\frac{1}{2}\left(\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} r_{A-A A_{1} A O / H O}^{2}}}+\frac{\frac{e^{2}}{8 \pi \varepsilon_{0} a_{0}}}{\frac{e^{2}}{8 \pi \varepsilon_{0} r_{A-A \mathrm{~A}_{2} A O / H O}}}\right)  \tag{15.103}\\
& =\frac{1}{2}\left(\frac{13.605804 \mathrm{eV}}{E_{\text {Coulomb }}\left(A-A . A_{1} A O / H O\right)}+\frac{13.605804 \mathrm{eV}}{E_{\text {Coulomb }}\left(A-A . A_{2} A O / H O\right)}\right)
\end{align*}
$$

In the exemplary cases of $C-N, C-O$, and $C-S$,

$$
\begin{equation*}
c_{2}^{\prime}=\frac{1}{2}\left(\frac{13.605804 \mathrm{eV}}{E_{\text {Coulomb }}\left(C-B C 2 s p^{3}\right)}+c_{2}(C \text { to } B)\right) \tag{15.104}
\end{equation*}
$$

where $C$ is carbon and $c_{2}(C$ to $B)$ is the hybridization factor of Eqs. (15.61) and (15.93) that matches the energy of the atom $B$ to that of the atom $C$ in the group. For these cases, the corresponding $E_{T}\left(\right.$ atom-atom, msp $\left.{ }^{3} . A O\right)$ term in Eq. (15.99) depends on the hybridization and bond order of the terminal atoms in the molecule, but typical values matching those used in the determination of the bond energies (Eq. (15.65)) are:

$$
\begin{aligned}
& E_{T}\left(C-O C 2 s p^{3} . O 2 p\right)=-1.44915 \mathrm{eV} ; \quad E_{T}\left(C-O C 2 s p^{3} . O 2 p\right)=-1.65376 \mathrm{eV} ; \quad E_{T}\left(C-N C 2 s p^{3} . N 2 p\right)=-1.44915 \mathrm{eV} ; \\
& E_{T}\left(C-S C 2 s p^{3} . S 2 p\right)=-0.72457 \mathrm{eV} ; \quad E_{T}(O-O O 2 p . O 2 p)=-1.44915 \mathrm{eV} ; \quad E_{T}(O-O O 2 p . O 2 p)=-1.65376 \mathrm{eV} \text {; } \\
& E_{T}(N-N N 2 p . N 2 p)=-1.44915 \mathrm{eV} ; \quad E_{T}(N-O N 2 p . O 2 p)=-1.44915 \mathrm{eV} ; \quad E_{T}(F-F F 2 p . F 2 p)=-1.44915 \mathrm{eV} \text {; } \\
& E_{T}(\mathrm{Cl}-\mathrm{ClCl} 3 \mathrm{p} . \mathrm{Cl} 3 \mathrm{p})=-0.92918 \mathrm{eV} ; \quad E_{T}(\mathrm{Br}-\mathrm{Br} \operatorname{Br} 4 \mathrm{p} . \mathrm{Br} 4 \mathrm{p})=-0.92918 \mathrm{eV} ; \quad E_{T}(I-I I 5 \mathrm{p} . I 5 \mathrm{p})=-0.36229 \mathrm{eV} \text {; }
\end{aligned}
$$

$$
\begin{aligned}
& E_{T}\left(C-F C 2 s p^{3} . F 2 p\right)=-1.85836 \mathrm{eV} ; E_{T}\left(C-C l C 2 s p^{3} \cdot C l 3 p\right)=-0.92918 \mathrm{eV} ; E_{T}\left(C-B r C 2 s p^{3} \cdot \mathrm{Br} 4 p\right)=-0.72457 \mathrm{eV} \\
& E_{T}\left(C-I C 2 s p^{3} . I 5 p\right)=-0.36228 \mathrm{eV}, \text { and } E_{T}(O-C l O 2 p \cdot C l 3 p)=-0.92918 \mathrm{eV} .
\end{aligned}
$$

In the case that the terminal bond is $X-X$ where $X$ is a halogen atom, $c_{1}$ is one, and $c_{2}^{\prime}$ is the average (Eq. (15.102)) of the hybridization factors of the participating halogen atoms given by Eqs. (15.71-15.72) where $E_{\text {Coulomb }}\left(\right.$ MO.atom, $\mathrm{msp}^{3}$ ) is determined using Eq. (15.32) and $E_{\text {Coulomb }}\left(\right.$ MO.atom, $\left.m s p^{3}\right)=13.605804 \mathrm{eV}$ for $X=I$. The factor $C_{1}$ of Eq. (15.99) is one for all halogen atoms. The factor $C_{2}$ of fluorine is one since it is the only halogen wherein the ionization energy is greater than that 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). For each of the other halogens, $\mathrm{Cl}, \mathrm{Br}$, and $I, C_{2}$ is the hybridization factor of Eq. (15.61) given by Eq. (15.79) with $c_{2}(1)$ being that of the halogen given by Eq. (15.77) that matches the valence energy of $X \quad\left(E_{1}(\right.$ valence $\left.)\right)$ to that of the $C 2 s p^{3} \mathrm{HO}$ $\left(E_{2}(\right.$ valence $)=-14.63489 \mathrm{eV}$, Eq. (15.25)) and to the hybridization of $C 2 s p^{3} \mathrm{HO}\left(c_{2}(2)=0.91771\right.$, Eq. (13.430)). $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of Eq. (15.99) is the maximum for the participating atoms which is $-1.44915 \mathrm{eV},-0.92918 \mathrm{eV}$, -0.92918 eV , and -0.33582 eV for $F, \mathrm{Cl}, \mathrm{Br}$, and $I$, respectively.

Consider the case that the terminal bond is $C-X$ where $C$ is a carbon atom and $X$ is a halogen atom. The factors $c_{1}$ and $C_{1}$ of Eq. (15.99) are one for all halogen atoms. For $X=F, c_{2}^{\prime}$ is the average (Eq. (15.104)) of the hybridization factors of the participating carbon and $F$ atoms where $c_{2}$ for carbon is given by Eq. (15.71) and $c_{2}$ for fluorine matched to carbon is given by Eq. (15.79) with $c_{2}(1)$ for the fluorine atom given by Eq. (15.77) that matches the valence energy of $F$ $\left(E_{1}(\right.$ valence $\left.)=-17.42282 \mathrm{eV}\right)$ to that of the $C 2 s p^{3} \mathrm{HO}\left(E_{2}(\right.$ valence $)=-14.63489 \mathrm{eV}$, Eq. (15.25)) and to the hybridization of $C 2 s p^{3} \mathrm{HO}\left(c_{2}(2)=0.91771\right.$, Eq. $\left.(13.430)\right)$. The factor $C_{2}$ of fluorine is one since it is the only halogen wherein the ionization energy is greater than that 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). For each of the other halogens, $C l, B r$, and $I, c_{2}^{\prime}$ is the hybridization factor of the participating carbon atom since the halogen atom is energy matched to the carbon atom. $C_{2}$ of the terminal-atom bond matches that used to determine the energies of the corresponding $C-X$-bond MO. Then, $C_{2}$ is the hybridization factor of Eq. (15.61) given by Eq. (15.79) with $c_{2}(1)$ for the halogen atom given by Eq. (15.77) that matches the valence energy of $X\left(E_{1}\right.$ (valence)) to that of the $C 2 s p^{3} \mathrm{HO}$ $\left(E_{2}(\right.$ valence $)=-14.63489 \mathrm{eV}$, Eq. (15.25)) and to the hybridization of $C 2 s p^{3} \mathrm{HO}\left(c_{2}(2)=0.91771\right.$, Eq. (13.430)). $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of Eq. (15.99) is the maximum for the participating atoms which is $-1.85836 \mathrm{eV},-0.92918 \mathrm{eV}$, -0.72457 eV , and -0.33582 eV for $\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$, and $I$, respectively.

Consider the case that the terminal bond is $H-X$ corresponding to the angle of the atoms $H C X$ where $C$ is a carbon atom and $X$ is a halogen atom. The factors $c_{1}$ and $C_{1}$ of Eq. (15.99) are 0.75 for all halogen atoms. For $X=F$, $c_{2}^{\prime}$ is given by Eq. (15.78) with $c_{2}$ of the participating carbon and $F$ atoms given by Eq. (15.71) and Eq. (15.74), respectively. The factor $C_{2}$ of fluorine is one since it is the only halogen wherein the ionization energy is greater than that 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). For each of the other halogens, $\mathrm{Cl}, \mathrm{Br}$, and $I, c_{2}^{\prime}$ is also given by Eq. (15.78) with $c_{2}$ of the participating carbon given by Eq. (15.71) and $c_{2}$ of the participating $X$ atom given by $c_{2}=0.91771$ (Eq. (13.430)) since the $X$ atom is energy matched to the $C 2 s p^{3} \mathrm{HO}$. In these cases, $C_{2}$ is given by Eq. (15.74) for the corresponding atom $X$ where $C_{2}$ matches the energy of the atom $X$ to that of $H$.

Using the distance between the two atoms $A$ and $B$ of the general molecular group $A C B$ when the total energy of the corresponding $A-B$ MO is zero, the corresponding bond angle can be determined from the law of cosines:

$$
\begin{equation*}
s_{1}^{2}+s_{2}^{2}-2 s_{1} s_{2} \operatorname{cosine} \theta=s_{3}^{2} \tag{15.105}
\end{equation*}
$$

With $s_{1}=2 c_{C-A}^{\prime}$, the internuclear distance of the $C-A$ bond, $s_{2}=2 c_{C-B}^{\prime}$, the internuclear distance of each $C-B$ bond, and $s_{3}=2{c^{\prime}}_{A-B}$, the internuclear distance of the two terminal atoms, the bond angle $\theta_{\angle A C B}$ between the $C-A$ and $C-B$ bonds is given by:

$$
\begin{align*}
& \left(2 c_{C-A}^{\prime}\right)^{2}+\left(2 c_{C-B}^{\prime}\right)^{2}-2\left(2{c_{C-A}^{\prime}}^{\prime}\right)\left(2 c_{C-B}^{\prime}\right) \operatorname{cosine} \theta=\left(2 c_{A-B}^{\prime}\right)^{2}  \tag{15.106}\\
& \theta_{\angle A C B}=\cos ^{-1}\left(\frac{\left(2 c_{C-A}^{\prime}\right)^{2}+\left(2 c_{C-B}^{\prime}\right)^{2}-\left(2 c_{A-B}^{\prime}\right)^{2}}{2\left(2 c_{C-A}^{\prime}\right)\left(2 c_{C-B}^{\prime}\right)}\right) \tag{15.107}
\end{align*}
$$

Consider the exemplary structure $C_{b} C_{a}\left(O_{a}\right) O_{b}$ wherein $C_{a}$ is bound to $C_{b}, O_{a}$, and $O_{b}$. In the general case that the three bonds are coplanar and two of the angles are known, say $\theta_{1}$ and $\theta_{2}$, then the third $\theta_{3}$ can be determined geometrically:

$$
\begin{equation*}
\theta_{3}=360-\theta_{1}-\theta_{2} \tag{15.108}
\end{equation*}
$$

In the general case that two of the three coplanar bonds are equivalent and one of the angles is known, say $\theta_{1}$, then the second and third can be determined geometrically:

$$
\begin{equation*}
\theta_{2}=\theta_{3}=\frac{\left(360-\theta_{1}\right)}{2} \tag{15.109}
\end{equation*}
$$

## ANGLES AND DISTANCES FOR AN MO THAT FORMS AN ISOSCELES TRIANGLE

In the general case where the group comprises three $A-B$ bonds having $B$ as the central atom at the apex of a pyramidal structure formed by the three bonds with the $A$ atoms at the base in the xy-plane. The $C_{3 v}$ axis centered on $B$ is defined as the vertical or z-axis, and any two $A-B$ bonds form an isosceles triangle. Then, the angle of the bonds and the distances from and along the z -axis are determined from the geometrical relationships given by Eqs. (13.412-13.416).
the distance $d_{\text {origin }-B}$ from the origin to the nucleus of a terminal $B$ atom is given by

$$
\begin{equation*}
d_{\text {origin }-B}=\frac{2 c_{B-B}^{\prime}}{2 \sin 60^{\circ}} \tag{15.110}
\end{equation*}
$$

the height along the z-axis from the origin to the $A$ nucleus $d_{\text {height }}$ is given by:

$$
\begin{equation*}
d_{\text {height }}=\sqrt{\left(2 c_{A-B}^{\prime}\right)^{2}-\left(d_{\text {origin-B }}\right)^{2}}, \text { and } \tag{15.111}
\end{equation*}
$$

the angle $\theta_{v}$ of each $A-B$ bond from the z -axis is given by:

$$
\begin{equation*}
\theta_{v}=\tan ^{-1}\left(\frac{d_{\text {origin }-B}}{d_{\text {height }}}\right) \tag{15.112}
\end{equation*}
$$

Consider the case where the central atom $B$ is further bound to a fourth atom $C$ and the $B-C$ bond is along the z-axis. Then, the bond $\theta_{\angle A B C}$ given by Eq. (14.206) is:

$$
\begin{equation*}
\theta_{\angle A B C}=180-\theta_{v} \tag{15.113}
\end{equation*}
$$

## DIHEDRAL ANGLE

Consider the plane defined by a general $A C A$ MO comprising a linear combination of two $C-A$-bond MOs where $C$ is the central atom. The dihedral angle $\theta_{\angle B C / A C A}$ between the $A C A$-plane and a line defined by a third bond with $C$, specifically that corresponding to a $C-B$-bond MO , is calculated from the bond angle $\theta_{\angle A C A}$ and the distances between the $A, B$, and $C$ atoms. The distance $d_{1}$ along the bisector of $\theta_{\angle A C A}$ from $C$ to the internuclear-distance line between $A$ and $A, 2 c_{A-A}^{\prime}$, is given by:

$$
\begin{equation*}
d_{1}=2 c_{C-A}^{\prime} \cos \frac{\theta_{\angle A C A}}{2} \tag{15.114}
\end{equation*}
$$

where $2{c^{\prime}}_{C-A}$ is the internuclear distance between $A$ and $C$. The atoms $A, A$, and $B$ define the base of a pyramid. Then, the pyramidal angle $\theta_{\angle A B A}$ can be solved from the internuclear distances between $A$ and $A, 2 c_{A-A}^{\prime}$, and between $A$ and $B, 2 c^{\prime}{ }_{A-B}$, using the law of cosines (Eq. (15.107)):

$$
\begin{equation*}
\theta_{\angle A B A}=\cos ^{-1}\left(\frac{\left(2 c_{A-B}^{\prime}\right)^{2}+\left(2 c_{A-B}^{\prime}\right)^{2}-\left(2 c_{A-A}^{\prime}\right)^{2}}{2\left(2 c_{A-B}^{\prime}\right)\left(2 c_{A-B}^{\prime}\right)}\right) \tag{15.115}
\end{equation*}
$$

Then, the distance $d_{2}$ along the bisector of $\theta_{\angle A B A}$ from $B$ to the internuclear-distance line $2 c^{\prime}{ }_{A-A}$, is given by:

$$
\begin{equation*}
d_{2}=2 c_{A-B}^{\prime} \cos \frac{\theta_{\angle A B A}}{2} \tag{15.116}
\end{equation*}
$$

The lengths $d_{1}, d_{2}$, and $2 c_{C-B}^{\prime}$ define a triangle wherein the angle between $d_{1}$ and the internuclear distance between $B$ and $C$, $2 c^{\prime}{ }_{C-B}$, is the dihedral angle $\theta_{\angle B C / A C A}$ that can be solved using the law of cosines (Eq. (15.107)):

$$
\begin{equation*}
\theta_{\angle B C / A C A}=\cos ^{-1}\left(\frac{d_{1}^{2}+\left(2{c^{\prime}}_{C-B}\right)^{2}-d_{2}^{2}}{2 d_{1}\left(2 c_{C-B}^{\prime}\right)}\right) \tag{15.117}
\end{equation*}
$$

## GENERAL DIHEDRAL ANGLE

Consider the plane defined by a general $A C B$ MO comprising a linear combination of $C-A$ and $C-B$-bond MOs where $C$ is the central atom. The dihedral angle $\theta_{\angle C D / A C B}$ between the $A C B$-plane and a line defined by a third bond of $C$ with $D$, specifically that corresponding to a $C-D$-bond MO, is calculated from the bond angle $\theta_{\angle A C B}$ and the distances between the $A$, $B, C$, and $D$ atoms. The distance $d_{1}$ from $C$ to the bisector of the internuclear-distance line between $A$ and $B, 2 c^{\prime}{ }_{A-B}$, is
given by two equations involving the law of cosines (Eq. (15.105)). One with $s_{1}=2 c_{C-A}^{\prime}$, the internuclear distance of the $C-A$ bond, $s_{2}=d_{1}, s_{3}=\frac{2 c_{A-B}^{\prime}}{2}$, half the internuclear distance between $A$ and $B$, and $\theta=\theta_{\angle A C d_{1}}$, the angle between $d_{1}$ and the $C-A$ bond is given by:

$$
\begin{equation*}
\left(2 c_{C-A}^{\prime}\right)^{2}+\left(d_{1}\right)^{2}-2\left(2 c_{C-A}^{\prime}\right)\left(d_{1}\right) \operatorname{cosine} \theta_{\angle A C d_{1}}=\left(\frac{2 c^{\prime}{ }_{A-B}}{2}\right)^{2} \tag{15.118}
\end{equation*}
$$

The other with $s_{1}=2 c_{C-B}^{\prime}$, the internuclear distance of the $C-B$ bond, $s_{2}=d_{1}, s_{3}=\frac{2 c_{A-B}^{\prime}}{2}$, and $\theta=\theta_{\angle A C B}-\theta_{\angle A C d_{1}}$ where $\theta_{\angle A C B}$ is the bond angle between the $C-A$ and $C-B$ bonds is given by:

$$
\begin{equation*}
\left(2 c_{C-B}^{\prime}\right)^{2}+\left(d_{1}\right)^{2}-2\left(2 c_{C-B}^{\prime}\right)\left(d_{1}\right) \operatorname{cosine}\left(\theta_{\angle A C B}-\theta_{\angle A C d_{1}}\right)=\left(\frac{2 c_{A-B}^{\prime}}{2}\right)^{2} \tag{15.119}
\end{equation*}
$$

Subtraction of Eq. (15.119) from Eq. (15.118) gives:

$$
\begin{equation*}
d_{1}=\frac{\left(2 c^{\prime}{ }_{C-A}\right)^{2}-\left(2{c^{\prime}}_{C-B}\right)^{2}}{2\left(\left(2 c_{C-A}^{\prime}\right) \operatorname{cosine} \theta_{\angle A C d_{1}}-\left(2 c_{C-B}^{\prime}\right) \operatorname{cosine}\left(\theta_{\angle A C B}-\theta_{\angle A C d_{1}}\right)\right)} \tag{15.120}
\end{equation*}
$$

Substitution of Eq. (15.120) into Eq. (15.118) gives

The angle between $d_{1}$ and the $C-A$ bond, $\theta_{\angle A C d_{1}}$, can be solved reiteratively using Eq. (15.121), and the result can be substituted into Eq. (15.120) to give $d_{1}$.

The atoms $A, B$, and $D$ define the base of a pyramid. Then, the pyramidal angle $\theta_{\angle A D B}$ can be solved from the internuclear distances between $A$ and $D, 2 c^{\prime}{ }_{A-D}$, between $B$ and $D, 2 c^{\prime}{ }_{B-D}$, and between $A$ and $B, 2 c^{\prime}{ }_{A-B}$, using the law of cosines (Eq. (15.107)):

$$
\begin{equation*}
\theta_{\angle A D B}=\cos ^{-1}\left(\frac{\left(2 c_{A-D}^{\prime}\right)^{2}+\left(2 c_{B-D}^{\prime}\right)^{2}-\left(2 c_{A-B}^{\prime}\right)^{2}}{2\left(2 c_{A-D}^{\prime}\right)\left(2 c_{B-D}^{\prime}\right)}\right) \tag{15.122}
\end{equation*}
$$

Then, the distance $d_{2}$ from $D$ to the bisector of the internuclear-distance line between $A$ and $B, 2 c^{\prime}{ }_{A-B}$, is given by two equations involving the law of cosines (Eq. (15.105)). One with $s_{1}=2 c_{A-D}^{\prime}$, the internuclear distance between $A$ and $D$, $s_{2}=d_{2}, s_{3}=\frac{2 c^{\prime}{ }_{A-B}}{2}$, half the internuclear distance between $A$ and $B$, and $\theta=\theta_{\angle A D d_{2}}$, the angle between $d_{2}$ and the $A-D$ axis is given by:

$$
\begin{equation*}
\left(2 c_{A-D}^{\prime}\right)^{2}+\left(d_{2}\right)^{2}-2\left(2 c_{A-D}^{\prime}\right)\left(d_{2}\right) \operatorname{cosine} \theta_{\angle A D d_{2}}=\left(\frac{2 c_{A-B}^{\prime}}{2}\right)^{2} \tag{15.123}
\end{equation*}
$$

The other with $s_{1}=2 c_{B-D}^{\prime}$, the internuclear distance between $B$ and $D, s_{2}=d_{2}$, and $\theta=\theta_{\angle A D B}-\theta_{\angle A D d_{2}}$ where $\theta_{\angle A D B}$ is the bond angle between the $A-D$ and $B-D$ axes is given by:

$$
\begin{equation*}
\left(2 c_{B-D}^{\prime}\right)^{2}+\left(d_{2}\right)^{2}-2\left(2 c_{B-D}^{\prime}\right)\left(d_{2}\right) \operatorname{cosine}\left(\theta_{\angle A D B}-\theta_{\angle A D d_{2}}\right)=\left(\frac{2 c_{A-B}^{\prime}}{2}\right)^{2} \tag{15.124}
\end{equation*}
$$

Subtraction of Eq. (15.124) from Eq. (15.123) gives:

$$
\begin{equation*}
d_{2}=\frac{\left(2 c_{A-D}^{\prime}\right)^{2}-\left(2{c^{\prime}}_{B-D}\right)^{2}}{2\left(\left(2 c_{A-D}^{\prime}\right) \operatorname{cosine} \theta_{\angle A D d_{2}}-\left(2 c_{B-D}^{\prime}\right) \operatorname{cosine}\left(\theta_{\angle A D B}-\theta_{\angle A D d 2}\right)\right)} \tag{15.125}
\end{equation*}
$$

Substitution of Eq. (15.125) into Eq. (15.123) gives:

$$
\left(\begin{array}{l}
\left(2 c_{A-D}^{\prime}\right)^{2}+\left(\frac{\left(2 c_{A-D}^{\prime}\right)^{2}-\left(2 c_{B-D}^{\prime}\right)^{2}}{2\left(\left(2 c_{A-D}^{\prime}\right) \operatorname{cosine} \theta_{\angle A D d_{2}}-\left(2 c_{B-D}^{\prime}\right) \operatorname{cosine}\left(\theta_{\angle A D B}-\theta_{\angle A D d_{2}}\right)\right)}\right)^{2}  \tag{15.126}\\
-2\left(2{c^{\prime}}_{A-D}\right)\left(\frac{\left(2{c^{\prime}}_{A-D}\right)^{2}-\left(2 c_{B-D}^{\prime}\right)^{2}}{2\left(\left(2{c^{\prime}}_{A-D}\right) \operatorname{cosine} \theta_{\angle A D d_{2}}-\left(2 c_{B-D}^{\prime}\right) \operatorname{cosine}\left(\theta_{\angle A D B}-\theta_{\angle A D d_{2}}\right)\right)}\right) \operatorname{cosine} \theta_{\angle A D d_{2}} \\
-\left(\frac{2{c^{\prime}}_{A-B}}{2}\right)^{2}
\end{array}\right)=0
$$

The angle between $d_{2}$ and the $A-D$ axis, $\theta_{\angle A D d_{2}}$, can be solved reiteratively using Eq. (15.126), and the result can be substituted into Eq. (15.125) to give $d_{2}$.

The lengths $d_{1}, d_{2}$, and $2 c^{\prime}{ }_{C-B}$ define a triangle wherein the angle between $d_{1}$ and the internuclear distance between $C$ and $D, 2 c_{C-D}^{\prime}$, is the dihedral angle $\theta_{\angle C D / A C B}$ that can be solved using the law of cosines (Eq. (15.107)):

$$
\begin{equation*}
\theta_{\angle C D / A C B}=\cos ^{-1}\left(\frac{d_{1}^{2}+\left(2 c^{\prime}{ }_{C-D}\right)^{2}-d_{2}^{2}}{2 d_{1}\left(2 c^{\prime}{ }_{C-D}\right)}\right) \tag{15.127}
\end{equation*}
$$

## SOLUTION OF GEOMETRICAL AND ENERGY PARAMETERS OF MAJOR FUNCTIONAL GROUPS AND CORRESPONDING ORGANIC MOLECULES

The exemplary molecules given in the following sections were solved using the solutions of organic chemical functional groups as basis elements wherein the structures and energies where linearly added to achieve the molecular solutions. Each functional group can be treated as a building block to form any desired molecular solution from the corresponding linear combination. Each functional group element was solved using the atomic orbital and hybrid orbital spherical orbitsphere solutions bridged by molecular orbitals comprised of the $\mathrm{H}_{2}$-type prolate spheroidal solution given in the Nature of the Chemical Bond of HydrogenType Molecules section. The energy of each MO was matched at the HO or AO by matching the hybridization and total energy of the MO to the AOs and HOs. The energy $E_{\text {mag }}$ (e.g. given by Eq. (15.67) for a $C 2 s p^{3} \mathrm{HO}$ and Eq. (15.68) for an $O 2 p \mathrm{AO}$ ) was subtracted for each set of unpaired electrons created by bond breakage.

The bond energy is not equal to the component energy of each bond as it exists in the molecule, although, they are close. The total energy of each group is its contribution to the total energy of the molecule as a whole. The determination of the bond energies for the creation of the separate parts must take into account the energy of the formation of any radicals and any redistribution of charge density within the pieces and the corresponding energy change with bond cleavage. Also, the vibrational energy in the transition state is dependent on the other groups that are bound to a given functional group. This will affect the functional-group energy. But, because the variations in the energy based on the balance of the molecular composition are typically of the order of a few hundreds of electron volts at most, they were neglected.

The energy of each functional-group MO bonding to a given carbon HO is independently matched to the HO by subtracting the contribution to the change in the energy of the HO from the total MO energy given by the sum of the MO contributions and $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (13.428)). The intercept angles are determined from Eqs. (15.80-15.87) using the final radius of the HO of each atom. The final carbon-atom radius is determined using Eqs. (15.32) wherein the sum of the energy contributions of each atom to all the MOs in which it participates in bonding is determined. This final radius is used in Eqs. (15.19) and (15.20) to calculate the final valence energy of the HO of each atom at the corresponding final radius. The radius of any bonding heteroatom that contributes to a MO is calculated in the same manner, and the energy of its outermost shell is matched to that of the MO by the hybridization factor between the carbon- HO energy and the energy of the heteroatomic shell. The donation of electron density to the AOs and HOs reduces the energy. The donation of the electron density to the MO's at each AO or HO is that which causes the resulting energy to be divided equally between the participating AOs or HOs to achieve energy matching.

The molecular solutions can be used to design synthetic pathways and predict product yields based on equilibrium constants calculated from the heats of formation. New stable compositions of matter can be predicted as well as the structures of combinatorial chemistry reactions. Further important pharmaceutical applications include the ability to graphically or computationally render the structures of drugs that permit the identification of the biologically active parts of the molecules to be identified from the common spatial charge-density functions of a series of active molecules. Drugs can be designed according to geometrical parameters and bonding interactions with the data of the structure of the active site of the drug.

To calculate conformations, folding, and physical properties, the exact solutions of the charge distributions in any given molecule are used to calculate the fields, and from the fields, the interactions between groups of the same molecule or between groups on different molecules are calculated wherein the interactions are distance and relative orientation dependent. The fields and interactions can be determined using a finite-element-analysis approach of Maxwell's equations.

## CONTINUOUS-CHAIN ALKANES ( $\left.C_{n} H_{2 n+2}, n=3,4,5 \ldots \infty\right)$

The continuous-chain alkanes, $C_{n} H_{2 n+2}$, are the homologous series comprising terminal methyl groups at each end of the chain with $n-2$ methylene $\left(\mathrm{CH}_{2}\right)$ groups in between:

$$
\begin{equation*}
\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{n-2} \mathrm{CH}_{3} \tag{15.128}
\end{equation*}
$$

$C_{n} H_{2 n+2}$ can be solved using the same principles as those used to solve ethane and ethylene wherein the $2 s$ and $2 p$ shells of each $C$ hybridize to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. Three $H$ AOs combine with three carbon $2 s p^{3}$ HOs and two $H$ AOs combine with two carbon $2 s p^{3}$ HOs to form each methyl and methylene group, respectively, where each bond comprises a $H_{2}$-type MO developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section. The $\mathrm{CH}_{3}$ and $\mathrm{CH}_{2}$ groups bond by forming $\mathrm{H}_{2}$ type MOs between the remaining $C 2 s p^{3} \mathrm{HOs}$ on the carbons such that each carbon forms four bonds involving its four $C 2 s p^{3}$ HOs. For the alkyl $C-C$ group, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -1.85836 eV where both energy contributions are given by Eq. (14.513). It is based on the energy match between the $C 2 s p^{3}$ HOs of the chain comprising methylene groups and terminal methyl groups.
The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of straight-chain alkanes are given in Tables $15.4,15.5$, and 15.6 , respectively. The total energy of each straightchain alkane given in Table 15.7 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.6 corresponding to functional-group composition of the molecule. The bond angle parameters of straight-chain alkanes determined using Eqs. (15.88-15.117) are given in Table 15.8. In this angle table and those given in subsequent sections when $c_{2}^{\prime}$ is given as the ratio of two values of $c_{2}$ designated to Atom 1 and Atom 2 and corresponding to $E_{\text {Coulombic }}$ of Atom 1 and Atom 2, respectively, then $c_{2}^{\prime}=\frac{c_{2}(\text { Atom } 2)}{c_{2}(\text { Atom } 1)}$. The color scale, translucent view of the charge-density of exemplary alkane, butane comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.1.

Figure 15.1. (A-B) Color scale, translucent and opaque views of the charge-density of butane. Each representation shows the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## BRANCHED ALKANES ( $\left.C_{n} H_{2 n+2}, n=3,4,5 \ldots \infty\right)$

The branched-chain alkanes, $\mathrm{C}_{n} \mathrm{H}_{2 n+2}$, comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-alkane groups are solved using the same principles as those used to solve the methyl and methylene functional groups wherein the $2 s$ and $2 p$ AOs of each $C$ hybridize to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ HOs to form a MO permits each participating hybridized orbital to decrease in radius and energy. $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of each $C-C$-bond MO in Eq. (15.61) due to the charge donation from the $C$ atoms to the MO is -1.85836 eV or -1.44915 eV based on the energy match between the $C 2 s p^{3}$ HOs corresponding to the energy contributions equivalent to those of methylene, -0.92918 eV (Eq. (14.513)), or methyl, -0.72457 eV (Eq. (14.151)), groups, respectively.

The symbols of the functional groups of branched-chain alkanes are given in Table 15.9. The geometrical (Eqs. (15.115.5 ) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of branchedchain alkanes are given in Tables $15.10,15.11$, and 15.12, respectively. The total energy of each branched-chain alkane given in Table 15.13 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.12 corresponding to functionalgroup composition of the molecule. The bond angle parameters of branched-chain alkanes determined using Eqs. (15.8815.117) are given in Table 15.14. The color scale, translucent view of the charge-density of exemplary alkane, isobutane, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.2.

Figure 15.2. Color scale, translucent view of the charge-density of isobutane showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (A) Top view. (B) Side view.

## ALKENES ( $\left.C_{n} H_{2 n}, n=3,4,5 \ldots \infty\right)$

The straight and branched-chain alkenes, $C_{n} H_{2 n}$, comprise at least one carbon-carbon double bond comprising a functional group that is solved equivalently to the double bond of ethylene. The double bond may be bound to one, two, three, or four carbon single bonds that substitute for the hydrogen atoms of ethylene. Based on the condition of energy matching of the orbital, any magnetic energy due to unpaired electrons in the constituent fragments, and differences in oscillation in the transition state, three distinct functional groups can be identified: $C$ vinyl single bond to $-C(C)=C, C$ vinyl single bond to $-\mathrm{C}(\mathrm{H})=\mathrm{C}$, and C vinyl single bond to $-\mathrm{C}(\mathrm{C})=\mathrm{CH}_{2}$. In addition, $\mathrm{CH}_{2}$ of the $-\mathrm{C}=\mathrm{CH}_{2}$ moiety is an alkene functional group.

The alkyl portion of the alkene may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in alkenes are equivalent to those in branched-chain alkanes. The solution of the functional groups comprises the hybridization of the $2 s$ and $2 p \mathrm{AOs}$ of each $C$ to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ HOs to form a MO permits each participating hybridized orbital to decrease in radius and energy. $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C=C$-bond MO in Eq. (15.61) due to the charge donation from the $C$ atoms to the MO is equivalent to that of ethylene, -2.26759 eV , given by Eq. (14.247). $\quad E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of each $C-C$-bond MO in Eq. (15.61) is -1.85836 eV or -1.44915 eV based on the energy match between the $C 2 s p^{3}$ HOs corresponding to the energy contributions equivalent to those of methylene, -0.92918 eV (Eq. (14.513)), or methyl, -0.72457 eV (Eq. (14.151)), groups, respectively.

The symbols of the functional groups of alkenes are given in Table 15.15. The geometrical (Eqs. (15.1-15.5) and (15.41)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.56)) parameters of alkenes are given in Tables $15.16,15.17$, and 15.18 , respectively. The total energy of each alkene given in Table 15.19 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.18 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C 2 s p^{3} \mathrm{HO}$ magnetic energy $E_{\text {mag }}$ that is subtracted from the weighted sum of the $E_{D}($ Group $)(\mathrm{eV})$ values based on composition is given by Eq. (15.67). The bond angle parameters of alkenes, determined using Eqs. (15.88-15.117), are given in Table 15.20. The color scale, translucent view of the charge-density of exemplary alkene, propene, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.3.

Figure 15.3. Color scale, translucent view of the charge-density of propene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). Table 15.19. The total bond energies of alkenes calculated using the functional group composition and the energies of Table 15.18 compared to the experimental

Table 15.20. The bond angle parameters of alkenes and experimental values [1]. In the calculation of $\theta_{v}$, the parameters from the preceding angle were used.

## ALKYNES ( $\left.C_{n} H_{2 n-2}, n=3,4,5 \ldots \infty\right)$

The straight and branched-chain alkynes, $C_{n} H_{2 n-2}$, have at least one carbon-carbon triple bond comprising a functional group that is solved equivalently to the triple bond of acetylene. The triple bond may be bound to one or two carbon single bonds that substitute for the hydrogen atoms of acetylene. Based on the energy matching of the mutually bound $C$, these $C-C$-bond MOs are defined as primary and secondary $C-C$ functional groups, respectively, that are unique to alkynes. In addition, the corresponding terminal CH of a primary alkyne comprises a functional group that is solved equivalently to the methylyne group of acetylene as given in the Acetylene Molecule section.

The alkyl portion of the alkyne may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in alkynes are equivalent to those in branched-chain alkanes.

The solution of the functional groups comprises the hybridization of the $2 s$ and $2 p$ AOs of each $C$ to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ HOs to form a MO permits each participating hybridized orbital to decrease in radius and energy. $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C \equiv C$-bond MO in Eq. (15.61) due to the charge donation from the $C$ atoms to the MO is equivalent to that of acetylene, -3.13026 eV , given by Eq. (14.342). $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of each -alkyl-bond MO in Eq. (15.61) is -1.85836 eV or -1.44915 eV based on the energy match between the $C 2 s p^{3}$ HOs corresponding to the energy contributions equivalent to those of methylene, -0.92918 eV (Eq. (14.513)), or methyl, -0.72457 eV (Eq. (14.151)), groups, respectively. For the $C-C$ groups each comprising a $C$ single bond to $C \equiv C, E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -0.72457 eV based on the energy match between the $C 2 s p^{3}$ HOs for the mutually bound $C$ of the single and triple bonds. The parameter $\omega$ of each group is matched for oscillation in the transition state based on the group being primary or secondary.

The symbols of the functional groups of alkynes are given in Table 15.21. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkynes are given in Tables $15.22,15.23$, and 15.24 , respectively. The total energy of each alkyne given in Table 15.25 is calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.24 corresponding to functional-group composition of the molecule. The bond angle parameters of alkynes determined using Eqs. $(15.88-15.117)$ are given in Table 15.26 . Each $C$ of the $C \equiv C$ group can further bond with only one atom, and the bond is linear as a minimum of energy as in the case of acetylene. The color scale, translucent view of the charge-density of exemplary alkyne, propyne, comprising the concentric shells of atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.4.

Figure 15.4. Color scale, translucent view of the charge-density of propyne showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

ALKYL FLUORIDES ( $C_{n} H_{2 n+2-m} F_{m}, n=1,2,3,4,5 \ldots \infty \quad m=1,2,3 \ldots \infty$ )
The branched-chain alkyl fluorides, $C_{n} H_{2 n+2-m} F_{m}$, may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds wherein at least one $H$ is replaced by a fluorine. The $C-F$ bond comprises a functional group for each case of $F$ replacing a $H$ of methane in the series $H_{4-m} C-F_{m}, m=1,2,3,4$, and $F$ replacing a $H$ of an alkane. The methyl, methylene, methylyne functional groups are equivalent to those of branched-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups that are equivalent to those of branched-chain alkanes.

The solution of the $C-F$ functional groups comprises the hybridization of the $2 s$ and $2 p$ AOs of each $C$ to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $F$ AO to form a molecular orbital (MO) permits each participating orbital to decrease in radius and energy. In alkyl fluorides, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $F \mathrm{AO}$ has an energy of $E(F)=-17.42282 \mathrm{eV}$. To meet the equipotential condition of the union of the $C-F H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $C-F$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } F\right)=\frac{E\left(C, 2 s p^{3}\right)}{E(F)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-14.63489 \mathrm{eV}}{-17.42282 \mathrm{eV}}(0.91771)=0.77087 \tag{15.129}
\end{equation*}
$$

$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-F$-bond MO in Eq. (15.61) based on the charge donation from $F$ to the MO is determined by the linear combination that results in a energy that is a minimum which does not exceed the energy of the AO of the $F$ atom to which it is energy matched.

The symbols of the functional groups of branched-chain alkyl fluorides are given in Table 15.27. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of branched-chain alkyl fluorides are given in Tables $15.28,15.29$, and 15.30 , respectively. The total energy of each branchedchain alkyl fluoride given in Table 15.31 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.30 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C 2 s p^{3}$ HO magnetic energy $E_{\text {mag }}$ that is subtracted from the weighted sum of the $E_{D}($ Group $)(\mathrm{eV})$ values based on composition is given by Eq. (15.67). In the case of trifluoromethane, $E_{\text {mag }}$ is positive since the term due to the fluorine atoms cancels that of the $C H$ group. The $C-C$ bonds to the $C H F$ group (one $H$ bond to $C$ ) were each treated as an iso $C-C$ bond. The $C-C$ bonds to the $C F$ group (no $H$ bonds to $C$ ) were each treated as a tert-butyl $C-C$. $E_{\text {mag }}$ was subtracted for each t-butyl group. The bond angle parameters of branched-chain alkyl fluorides determined using Eqs. (15.70-15.79), (15.8715.117 ) and (15.129) are given in Table 15.32. The color scale, translucent view of the charge-density of exemplary alkyl fluoride, 1-fluoropropane, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.5.

Figure 15.5. Color scale, translucent view of the charge-density of 1 -fluoropropane showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

ALKYL CHLORIDES ( $\left.C_{n} H_{2 n+2-m} C l_{m}, \quad n=1,2,3,4,5 \ldots \infty \quad m=1,2,3 \ldots \infty\right)$
The branched-chain alkyl chlorides, $C_{n} H_{2 n+2-m} C l_{m}$, may comprise at least two terminal methyl groups ( $\mathrm{CH}_{3}$ ) at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds wherein at least one $H$ is replaced by a chlorine. The $\mathrm{C}-\mathrm{Cl}$ bond comprises a functional group for each case of Cl replacing a H of methane for the series $\mathrm{H}_{4-m} \mathrm{C}-\mathrm{Cl}_{m}, m=1,2,3$, with the $\mathrm{C}-\mathrm{Cl}$ bond of $\mathrm{CCl}_{4}$ comprising another functional group due to the limitation of the minimum energy of Cl matched to that of the $\mathrm{C} 2 s \mathrm{sp}^{3} \mathrm{HO}$. In addition, the $\mathrm{C}-\mathrm{Cl}$ bond due to Cl replacing an $H$ of an alkane is a functional group. The methyl, methylene, methylyne functional groups are equivalent to those of branched-chain alkanes. Six types of $C-C$ bonds can be identified. The n -alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups that are equivalent to those of branched-chain alkanes.

The solution of the $C-C l$ functional groups comprises the hybridization of the $2 s$ and $2 p$ AOs of each $C$ to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the Cl AO to form a MO permits each participating orbital to decrease in radius and energy. In alkyl chlorides, the energy of chlorine is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{2}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $C_{2}$ parameter. Then, $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the Cl AO has an energy of $E(\mathrm{Cl})=-12.96764 \mathrm{eV}$. To meet the equipotential condition of the union of the $\mathrm{C}-\mathrm{Cl} \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $C_{2}$ of Eq. (15.61) for the $C-C l$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Cl}\right)=\frac{E(C l)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-12.96764 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.81317 \tag{15.130}
\end{equation*}
$$

The valence energy of the carbon $2 p$ is -11.2603 eV and that of the Cl AO is -12.96764 eV . The energy difference is more than that of $2 E_{T}\left(C-C, 2 s p^{3}\right)$ given by Eq. (14.151) for a single bond. Thus, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $\mathrm{C}-\mathrm{Cl}$-bond MO of $\mathrm{CCl}_{m} H_{4-m}$ and $C_{n} \mathrm{H}_{2 n+2-m} \mathrm{Cl}_{m}$ in Eq. (15.61) due to the charge donation from the C and Cl atoms to the MO is -1.44915 eV based on the energy match between the $C 2 s p^{3} \mathrm{HO}$ and the Cl AO corresponding to the energy contributions equivalent to those of methyl groups, -0.72457 eV (Eq. (14.151)). $\quad E_{T}\left(\right.$ atom-atom, $m s p^{3} . \mathrm{AO}$ ) of the $\mathrm{C}-\mathrm{Cl}$-bond MO of chloroform with four $\mathrm{C}-\mathrm{Cl}$ bonds is -0.92918 eV (Eq. (14.513)) based on the maximum single-bond-energy contribution of the $C 2 s p^{3} \mathrm{HO}$.

The symbols of the functional groups of branched-chain alkyl chlorides are given in Table 15.33. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of branched-chain alkyl chlorides are given in Tables $15.34,15.35$, and 15.36 , respectively. The total energy of each branchedchain alkyl chloride given in Table 15.37 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.36 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C 2 s p^{3}$ HO magnetic energy $E_{\text {mag }}$ that was subtracted from the weighted sum of the $E_{D}($ Group $)(\mathrm{eV})$ values based on composition is given by Eq. (15.67). The $C-C$ bonds to the CHCl group (one $H$ bond to $C$ ) were each treated as an iso $C-C$ bond. The $C-C$ bonds to the $C C l$ group (no $H$ bonds to $C$ ) were each treated as a tert-butyl $C-C$. $E_{\operatorname{mag}}$ was subtracted for each t-butyl group. The bond angle parameters of branched-chain alkyl chlorides determined using Eqs. (15.7015.79), ( $15.88-15.117$ ) and ( 15.130 ) are given in Table 15.38. The color scale, translucent view of the charge-density of exemplary alkyl chloride, 1 -chloropropane, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.6.

Figure 15.6. Color scale, translucent view of the charge-density of 1 -chloropropane showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.33. The symbols of functional groups of branched-chain alkyl chlorides.

| Functional Group | Group Symbol |
| :---: | :---: |
| CCl of $\mathrm{CCl}_{m} \mathrm{H}_{4-m}$ | $\mathrm{C}-\mathrm{Cl}$ (i) |

## ALKYL BROMIDES ( $\left.C_{n} H_{2 n+2-m} B r_{m}, n=1,2,3,4,5 \ldots \infty \quad m=1,2,3 \ldots \infty\right)$

The branched-chain alkyl bromides, $C_{n} H_{2 n+2-m} B r_{m}$, may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene ( $\mathrm{CH}_{2}$ ), and methylyne ( CH ) functional groups as well as $C$ bound by carbon-carbon single bonds wherein at least one $H$ is replaced by a bromine. The $\mathrm{C}-\mathrm{Br}$ bond comprises a functional group for each case of Br replacing a H of methane for the series $\mathrm{H}_{4-m} \mathrm{C}-\mathrm{Br} r_{m}, m=1,2,3$, with the $\mathrm{C}-\mathrm{Br}$ bond of $\mathrm{CBr}_{4}$ comprising another functional group due to the limitation of the minimum energy of Br matched to that of the $\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO}$. In addition, the $\mathrm{C}-\mathrm{Br}$ bond due to Br replacing a H of an alkane is a functional group. The methyl, methylene, methylyne functional groups are equivalent to those of branched-chain alkanes. Six types of $C-C$ bonds can be identified. The $n$-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups that are equivalent to those of branched-chain alkanes.

The solution of the $C-B r$ functional groups comprises the hybridization of the $2 s$ and $2 p$ shells of each $C$ to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3}$ hybridized orbital (HO) and the Br AO to form a molecular orbital (MO) permits each participating orbital to decrease in radius and energy. In alkyl bromides, the energy of bromine is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{2}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $C_{2}$ parameter. Then, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the Br AO has an energy of $E(B r)=-11.81381 \mathrm{eV}$. To meet the equipotential condition of the union of the $\mathrm{C}-\mathrm{Br} \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $C_{2}$ of Eq. (15.61) for the $C-B r$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{Br}\right)=\frac{E(B r)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-11.81381 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.74081 \tag{15.131}
\end{equation*}
$$

The valence energy of the carbon $2 p$ is -11.2603 eV and that of the Br AO is -11.81381 eV . The energy difference is less than that of $E_{T}\left(C-C, 2 s p^{3}\right)$ given by Eq. (14.151) for a single bond. Thus, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the alkyl $C-B r-$ bond MO in Eq. (15.61) due to the charge donation from the $C$ and Br atoms to the MO is -0.92918 eV (Eq. (14.513)) based on the maximum single-bond-energy contribution of the $C 2 s p^{3} \mathrm{HO} . E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the series $\mathrm{CBr}_{m} \mathrm{H}_{4-m} m=1,2,3$ is equivalent to those of methyl groups, -0.72457 eV (Eq. (14.151)). For $\mathrm{CBr}_{4}$, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-B r$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $B r$ atoms to the MO is -0.36229 eV based on the maximum charge density on the $C 2 s p^{3} \mathrm{HO}$. It is given by Eqs. (15.18-15.20) and Eq. (15.29) with a linear combination of $s=1$ corresponding to $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=-0.72457 \mathrm{eV}$ and $s=0$ corresponding to: $E_{T}\left(\right.$ atom-atom,$\left.m s p^{3} . A O\right)=0$.

The symbols of the functional groups of branched-chain alkyl bromides are given in Table 15.39. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of branched-chain alkyl bromides are given in Tables $15.49,15.50$, and 15.51 , respectively. The total energy of each branchedchain alkyl bromide given in Table 15.52 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.51 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C 2 s p^{3}$ HO magnetic energy $E_{\text {mag }}$ that was subtracted from the weighted sum of the $E_{D}($ Group $)(e V)$ values based on composition is given by Eq. (15.67). The $C-C$ bonds to the CHBr group (one $H$ bond to $C$ ) were each treated as an iso $C-C$ bond. The $C-C$ bonds to the $C B r$ group (no $H$ bonds to $C$ ) were each treated as a tert-butyl $C-C$. The bond angle parameters of branched-chain alkyl bromides determined using Eqs. (15.70-15.79), (15.88-15.117) and (15.131) are given in Table 15.44. The color scale, translucent view of the charge-density of exemplary alkyl bromide, 1 -bromopropane, comprising the concentric shells of atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.7.

Figure 15.7. Color scale, translucent view of the charge-density of 1 -bromopropane showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.42. The energy parameters ( eV ) of functional groups of branched-chain alkyl bromides

Table 15.44. The bond angle parameters of branched-chain alkyl bromides and experimental values [1]. In the calculation of $\theta_{v}$, the parameters from the preceding

## ALKYL IODIDES ( $\left.C_{n} H_{2 n+2-m} I_{m}, \quad n=1,2,3,4,5 \ldots \infty m=1,2,3 \ldots \infty\right)$

The branched-chain alkyl iodides, $\mathrm{C}_{n} \mathrm{H}_{2 n+2-m} I_{m}$, may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds wherein at least one $H$ is replaced by an iodine atom. The $C-I$ bond comprises a functional group for $I$ replacing a $H$ of methane $\left(\mathrm{CH}_{3} I\right)$ or for $I$ replacing a $H$ of an alkane corresponding to the series $C_{n} H_{2 n+2-m} I_{m}$. The $C-I$ bond of each of $\mathrm{CH}_{2} \mathrm{I}_{2}$ and $\mathrm{CHI}_{3}$ comprise separate functional groups due to the limitation of the minimum energy of $I$ matched to that of the $C 2 s p^{3} \mathrm{HO}$. The methyl, methylene, methylyne functional groups are equivalent to those of branchedchain alkanes. Six types of $C-C$ bonds can be identified. The $n$-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups that are equivalent to those of branched-chain alkanes.

The solution of the $C-I$ functional groups comprises the hybridization of the $2 s$ and $2 p$ AOs of each $C$ to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $I \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. In alkyl iodides, the energy of iodine is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{2}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $C_{2}$ parameter. Then, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)). The $I$ AO has an energy of $E(I)=-10.45126 \mathrm{eV}$. To meet the equipotential condition of the union of the $C-I \quad H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $C_{2}$ of Eq. (15.60) for the $C-I$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
C_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{I}\right)=\frac{E(I)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-10.45126 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.65537 \tag{15.132}
\end{equation*}
$$

The valence energy of the carbon $2 p$ is -11.2603 eV and that of the $I \mathrm{AO}$ is -10.45126 eV . The energy difference is positive. Thus, based on the maximum charge density on the $C 2 s p^{3} \mathrm{HO} E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-I$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $I$ atoms to the MO is -0.36229 eV (Eqs. (15.18-15.20 and Eq. (15.29) with a linear combination of $s=1, E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=-0.72457 \mathrm{eV}$ and $E_{T}\left(\right.$ atom-atom, $\left.\left.m s p^{3} . A O\right)=0\right)$ for methyl and alkyl iodides, -0.18114 eV for diiodomethane, and 0 for $\mathrm{CHI}_{3}$.

The symbols of the functional groups of branched-chain alkyl iodides are given in Table 15.45. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of branched-chain alkyl iodides are given in Tables $15.55,15.56$, and 15.57 , respectively. The total energy of each branched-chain alkyl iodide given in Table 15.49 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.48 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C 2 s p^{3} \mathrm{HO}$ magnetic energy $E_{\text {mag }}$ that was subtracted from the weighted sum of the $E_{D}($ Group $)(e V)$ values based on composition is given by Eq. (15.67). The $C-C$ bonds to the $C H I$ group (one $H$ bond to $C$ ) were each treated as an iso $C-C$ bond. The $C-C$ bonds to the $C I$ group (no $H$ bonds to $C$ ) were each treated as a tert-butyl $C-C$. $E_{\text {mag }}$ is subtracted for each t-butyl group. The bond angle parameters of branched-chain alkyl iodides determined using Eqs. (15.70-15.79), (15.8815.117 ) and (15.132) are given in Table 15.50. The color scale, translucent view of the charge-density of exemplary alkyl iodide, 1-iodopropane, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.8.

Figure 15.8. Color scale, translucent view of the charge-density of 1-iodopropane showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.50. The bond angle parameters of branched-chain alkyl iodides and experimental values [1]. In the calculation of $\theta_{v}$, the parameters from the preceding angle were used. $E_{T}$ is $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$.

## ALKENYL HALIDES ( $\left.C_{n} H_{2 n-m} X_{m}, \quad n=3,4,5 \ldots \infty \quad m=1,2,3 \ldots \infty\right)$

The branched-chain alkenyl halides, $C_{n} H_{2 n+2-m} X_{m}$ with $X=F, C l, B r, I$, may comprise alkyl and alkenyl functional groups wherein at least one $H$ is replaced by a halogen atom. In the case that a halogen atom replaces an alkyl $H$, the $C-X$ bond comprises the alkyl-halogen functional groups given in their respective sections. The alkenyl halogen $C-X$ bond comprises a separate functional group for each case of $X$ bonding to the $C=C$-bond functional group given in the Alkenes section. In addition the CH group of the moiety $\mathrm{XCH}=\mathrm{C}$ comprises a functional group unique to alkenyl halides. The straight and branched-chain alkenes, $C_{n} H_{2 n}$, comprise at least one carbon-carbon double bond comprising a functional group that is solved equivalently to the double bond of ethylene. The double bond may be bound to one, two, three, or four carbon single bonds that substitute for the hydrogen atoms of ethylene. The three distinct functional groups given in the Alkenes section are $C$ vinyl single bond to $-\mathrm{C}(\mathrm{C})=\mathrm{C}, \mathrm{C}$ vinyl single bond to $-\mathrm{C}(\mathrm{H})=\mathrm{C}$, and C vinyl single bond to $-\mathrm{C}(\mathrm{C})=\mathrm{CH}_{2}$. In addition, $\mathrm{CH}_{2}$ of the $-\mathrm{C}=\mathrm{CH}_{2}$ moiety is also an alkene functional group solved in the Alkenes section.

Consider the case where $X=C l$ substitutes for a carbon single bond or a hydrogen atom. Based on the condition of energy matching of the orbital, any magnetic energy due to unpaired electrons in the constituent fragments, and differences in oscillation in the transition state, two distinct $C-C l$ functional groups can be identified: Cl vinyl single bond to $-C(C)=C$ and Cl vinyl single bond to $-C(H)=C$. The alkenyl-halide $C H$ group is equivalent to that solved in the Hydrogen Carbide ( CH ) section except that $\Delta E_{\mathrm{H}_{2} M O}(\mathrm{AO} / \mathrm{HO})=-1.13379 \mathrm{eV}$ in order to energy match to the $\mathrm{C}-\mathrm{Cl}$ and $\mathrm{C}=\mathrm{C}$ bonds.

The alkyl portion of the alkenyl halide may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkene halides are equivalent to those in branched-chain alkanes.
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C=C$-bond MO in Eq. (15.61) due to the charge donation from the $C$ atoms to the MO is equivalent to that of ethylene, -2.26759 eV , given by Eq. (14.247). $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of each $C-C$-bond MO in Eq. (15.61) is -1.85836 eV or -1.44915 eV based on the energy match between the $C 2 \mathrm{sp}^{3} \mathrm{HOs}$ corresponding to the energy contributions equivalent to those of methylene, -0.92918 eV (Eq. (14.513), or methyl, -0.72457 eV (Eq. (14.151)), groups, respectively.

The solution of each $C-X$ functional group comprises the hybridization of the $2 s$ and $2 p$ AOs of the $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $X$ AO to form a MO permits each participating orbital to decrease in radius and energy. The alkenyl $C-X$-bond functional groups comprise single bonds and are equivalent to those of the corresponding alkyl halides except that the halogen AO and the $C-X$-bond MO are each energy matched to the alkene $C 2 s p^{3} \mathrm{HO}$. In alkenyl halides with $X=C l, B r$, or $I$, the energy of the halogen atom is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264)). Thus, $c_{2}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $C_{2}$ parameter. For example, the hybridization factor $C_{2}$ of Eq. (15.61) for the alkenyl $\mathrm{C}-\mathrm{Cl}$-bond MO given by Eq. (15.130) is $C_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to Cl$)=0.81317$.
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the alkenyl $C-C l$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and Cl atoms to the MO is -1.44915 eV for the Cl vinyl single bond to $-\mathrm{C}(\mathrm{H})=\mathrm{C} \mathrm{C}-\mathrm{Cl}$ group and -0.92918 eV for the Cl vinyl single bond to $-C(C)=C C-C l$ group. It is based on the energy match between the $C l$ atom and the $C 2 s p^{3} \mathrm{HO}$ of an unsubstituted vinyl group and a substituted vinyl group given by Eqs. (14.151) and (14.513), respectively.

The symbols of the functional groups of branched-chain alkenyl chlorides are given in Table 15.51. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of branched-chain alkenyl chlorides are given in Tables 15.52, 15.53, and 15.54, respectively. The total energy of each branchedchain alkenyl chloride given in Table 15.55 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.54 corresponding to functional-group composition of the molecule. The bond angle parameters of branched-chain alkenyl chlorides determined using Eqs. (15.70-15.79), (15.88-15.117) and (15.130) are given in Table 15.56. The color scale, translucent view of the charge-density of exemplary alkenyl halide, 2-chloropropene, comprising the concentric shells of atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.9.

Figure 15.9. Color scale, translucent view of the charge-density of 2-chloropropene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## ALCOHOLS ( $\left.C_{n} H_{2 n+2} O_{m}, \quad n=1,2,3,4,5 \ldots \infty\right)$

The alkyl alcohols, $C_{n} H_{2 n+2} O_{m}$, comprise an OH functional group and two types of $\mathrm{C}-\mathrm{O}$ functional groups, one for methyl alcohol and the other for general alkyl alcohols. The alkyl portion of the alkyl alcohol may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne ( CH ) functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straightchain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alcohols are equivalent to those in branched-chain alkanes.

The $O H$ functional group was solved in the Hydroxyl Radical $(O H)$ section. Each $C-O$ group is solved by hybridizing the $2 s$ and $2 p$ AOs of the $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $O \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. In alkyl alcohols, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)) and the $O$ AO has an energy of $E(O)=-13.61806 \mathrm{eV}$. To meet the equipotential condition of the union of the $\mathrm{C}-\mathrm{O} \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $C-O$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } O\right)=\frac{E(O)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-13.61806 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.85395 \tag{15.133}
\end{equation*}
$$

$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-O$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $O$ atoms to the MO is -1.65376 eV for the $\mathrm{CH}_{3}-\mathrm{OH} \mathrm{C}-\mathrm{O}$ group. It is based on the energy match between the OH group and the $\mathrm{C} 2 s p^{3}$ HO of a methyl group and is given by the linear combination of -0.92918 eV (Eq. (14.513)) and -0.72457 eV (Eq. (14.151)), respectively. For the alkyl $C-O$ group, $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ is -1.85836 eV . It is based on the energy match between the $O \mathrm{AO}$ and the $C 2 s p^{3} \mathrm{HO}$ of a methylene group where both energy contributions are given by Eq. (14.513).

The symbols of the functional groups of branched-chain alkyl alcohols are given in Table 15.66. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl alcohols are given in Tables 15.58, 15.59, and 15.60, respectively. The total energy of each alkyl alcohol given in Table 15.61 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.60 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl alcohols determined using Eqs. (15.88-15.117) are given in Table 15.62. The color scale, translucent view of the charge-density of exemplary alcohol, 1-propanol, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.10.

Figure 15.10. Color scale, translucent view of the charge-density of 1-propanol showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). ETHERS ( $\left.C_{n} H_{2 n+2} O_{m}, n=2,3,4,5 \ldots \infty\right)$
The alkyl ethers, $C_{n} H_{2 n+2} O_{m}$, comprise two types of $C-O$ functional groups, one for methyl or t-butyl groups corresponding to the $C$ and the other for general alkyl groups. The alkyl portion of the alkyl ether may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The $n$-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in ethers are equivalent to those in branched-chain alkanes.

Each $C-O$ group is solved by hybridizing the $2 s$ and $2 p$ AOs of the $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $O$ AO to form a MO permits each participating orbital to decrease in radius and energy. In alkyl ethers, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) and an energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)) and the $O$ AO has an energy of $E(O)=-13.61806 \mathrm{eV}$. To meet the equipotential condition of the union of the $\mathrm{C}-\mathrm{O} \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $C-O$-bond MO given by Eq. (15.133) is $c_{2}\left(C 2 s p^{3} H O\right.$ to $\left.O\right)=0.85395$. $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $\mathrm{C}-\mathrm{O}$-bond MO in Eq. (15.52) due to the charge donation from the $C$ and $O$ atoms to the MO is -1.44915 eV for the $\mathrm{CH}_{3}-\mathrm{O}$ - and $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}-\mathrm{O}-\mathrm{C}-\mathrm{O}$ groups. It is based on the energy match between the O AO , initially at the Coulomb potential of a proton and an electron (Eqs. (1.257) and (10.162), respectively), and the $C 2 s p^{3} \mathrm{HO}$ of a methyl group as given by Eq. (14.151). For the alkyl $C-O$ group, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -1.65376 eV . It is based on the energy match between the $O \mathrm{AO}$ and the $C 2 s p^{3} \mathrm{HO}$ of a methylene group and is given by the linear combination of -0.72457 eV (Eq. (14.151)) and -0.92918 eV (Eq. (14.513)), respectively.

The symbols of the functional groups of branched-chain alkyl ethers are given in Table 15.63. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl ethers are given in Tables 15.64, 15.65, and 15.66, respectively. The total energy of each alkyl ether given in Table 15.67 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.66 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl ethers determined using Eqs. (15.88-15.117) are given in Table 15.68. The color scale, translucent view of the charge-density of exemplary ether, diethyl ether, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.11.

Figure 15.11. Color scale, translucent view of the charge-density of diethyl ether showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (A) Oblique view. (B) View along the nitrogen atom.

Table 15.67. The total bond energies of alkyl ethers calculated using the functional group composition and the energies of Table 15.66 compared to the experimental
values [3].

Table 15.68. The bond angle parameters of alkyl ethers and experimental values [1]. In the calculation of $\theta_{v}$, the parameters from the preceding angle were used. $E_{T}$ is $E_{7}\left(\right.$ atom - atom,$\left.m s p^{3} . A O\right)$.

PRIMARY AMINES ( $\left.C_{n} H_{2 n+2+m} N_{m}, n=1,2,3,4,5 \ldots \infty\right)$
The primary amines, $\mathrm{C}_{n} \mathrm{H}_{2 n+2+m} N_{m}$, comprise an $\mathrm{NH}_{2}$ functional group and a $\mathrm{C}-\mathrm{N}$ functional group. The alkyl portion of the primary amine may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne ( CH ) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $\mathrm{C}-\mathrm{C}$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and tbutyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in primary amines are equivalent to those in branched-chain alkanes.

The primary amino $\left(\mathrm{NH}_{2}\right)$ functional group was solved using the procedure given in the Dihydrogen Nitride $\left(\mathrm{NH}_{2}\right)$ section. Using the results of Eqs. (13.245-13.368), the primary amino parameters in Eq. (15.61) are $n_{1}=2, C_{1}=0.75$, $C_{2}=0.93613$ (Eqs. (13.248-13.249)), $C_{1 o}=1.5$, and $c_{1}=0.75$. In primary amines, the $C 2 s p^{3} \mathrm{HO}$ of the $C-N H_{2}$-bond MO has an energy of $E\left(C, 2 s p^{3}\right)=-15.35946 \mathrm{eV}$ (Eq. (15.18) with $s=1$ and Eqs. (15.19-15.20)) and the $N$ AO has an energy of $E(N)=-14.53414 \mathrm{eV}$. To meet the equipotential condition of the union of the $\mathrm{N}-\mathrm{H} \mathrm{H}_{2}$-type-ellipsoidal-MO with the $C 2 s p^{3} \mathrm{HO}$, the hybridization factor $c_{2}$ of Eq. (15.61) for the $N-H$-bond MO given by Eq. (15.77) is:

$$
\begin{equation*}
c_{2}\left(H \text { to } 1^{\circ} N\right)=\frac{E(N)}{E\left(C, 2 s p^{3}\right)}=\frac{-14.53414 \mathrm{eV}}{-15.35946 \mathrm{eV}}=0.94627 \tag{15.134}
\end{equation*}
$$

The $C-N$ group is solved by hybridizing the $2 s$ and $2 p$ AOs of the $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $N \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. In primary amines, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $N$ AO has an energy of $E(N)=-14.53414 \mathrm{eV}$. To meet the equipotential condition of the union of the $\mathrm{C}-\mathrm{N} \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $C-N$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{N}\right)=\frac{E(N)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} \mathrm{HO}\right)=\frac{-14.53414 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.91140 \tag{15.135}
\end{equation*}
$$

$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-N$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $N$ atoms to the MO is -1.44915 eV . It is based on the energy match between the N of the $\mathrm{NH}_{2}$ group and the $\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO}$ corresponding to the energy contributions to the single bond that are equivalent to those of methyl groups, -0.72457 eV (Eq. (14.151)), where the $N-H$ bonds are also energy matched to the $C-N$ bond.

The symbols of the functional groups of branched-chain primary amines are given in Table 15.69. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of primary amines are given in Tables $15.70,15.71$, and 15.72 , respectively. The total energy of each primary amine given in Table 15.73 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.72 corresponding to functional-group composition of the molecule. The bond angle parameters of primary amines determined using Eqs. (15.88-15.117) are given in Table 15.74. The color scale, translucent view of the charge-density of exemplary primary amine, propylamine, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.12.

Figure 15.12. (A)-(B) Color scale, translucent views of the charge-density of propylamine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## SECONDARY AMINES ( $\left.C_{n} H_{2 n+2+m} N_{m}, n=2,3,4,5 \ldots \infty\right)$

The secondary amines, $C_{n} H_{2 n+2+m} N_{m}$, comprise an $N H$ functional group and two types of $C-N$ functional groups, one for the methyl group corresponding to the $C$ of $C-N$ and the other for general alkyl secondary amines. The alkyl portion of the secondary amine may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $\mathrm{C}-\mathrm{C}$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in secondary amines are equivalent to those in branched-chain alkanes.

The secondary amino ( $N H$ ) functional group was solved using the procedure given in the Hydrogen Nitride ( NH ) section. Using the results of Eqs. (13.245-13.316), the secondary amino parameters in Eq. (15.61) are $n_{1}=1, C_{1}=0.75$, $C_{2}=0.93613$ (Eqs. (13.248-13.249)), $C_{1 o}=0.75$, and $c_{1}=0.75$. In secondary amines, the $C 2 s p^{3} \mathrm{HO}$ of the $C-N H$-bond MO has an energy of $E\left(C, 2 s p^{3}\right)=-15.56407 \mathrm{eV}$ (Eqs. (14.514-14.516)); Eq. (15.29) with $s=1$ and $s=2$, Eq. (15.31), and Eqs. (15.19-15.20)) and the $N$ AO has an energy of $E(N)=-14.53414 \mathrm{eV}$ (Eq. (13.251)). To meet the equipotential condition of the union of the $\mathrm{N}-\mathrm{H}_{2} \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with the $\mathrm{C} 2 s p^{3} \mathrm{HO}$, the hybridization factor $c_{2}$ of Eq. (15.61) for the $N-H-$ bond MO given by Eq. (15.77) is:

$$
\begin{equation*}
c_{2}\left(\text { H to } 2^{\circ} N\right)=\frac{E(N)}{E\left(C, 2 s p^{3}\right)}=\frac{-14.53414 \mathrm{eV}}{-15.56407 \mathrm{eV}}=0.93383 \tag{15.136}
\end{equation*}
$$

The $C-N$ group is solved by hybridizing the $2 s$ and $2 p$ AOs of the $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $N \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. In secondary amines, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $N$ AO has an energy of $E(N)=-14.53414 \mathrm{eV}$. To meet the equipotential condition of the union of the $\mathrm{C}-\mathrm{N} \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $C-N$-bond MO given by Eq. (15.135) is $c_{2}\left(C 2 s p^{3} H O\right.$ to $\left.N\right)=0.91140$.

As given in the Continuous-Chain Alkanes $\left(C_{n} H_{2 n+2}, n=3,4,5 \ldots \infty\right)$ section, each methylene group forms two single bonds, and the energy of each $\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO}$ of each $\mathrm{CH}_{2}$ group alone is given by that in ethylene, -1.13379 eV (Eq. (14.511)). In secondary amines, the $N$ of the $N H$ group also binds to two $C 2 s p^{3} \mathrm{HOs}$ and the corresponding $E_{T}\left(\right.$ atom-atom,msp ${ }^{3}$.AO) of each $C-N$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $N$ atoms to the MO is -1.13379 eV . It is based on the energy match between the $N$ of the $N H$ group to the two $C 2 s p^{3}$ HOs corresponding to the energy contributions to each of the two single bonds that are equivalent to those of independent methylene groups, -1.13379 eV (Eq. (14.511)), where the $N-H$ bond is also energy matched to the $C-N$ bonds. $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-N$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $N$ atoms to the MO is -1.13379 eV . It is based on the energy match between the $N$ of the $N H$ group to two $C 2 s p^{3}$ HOs corresponding to the energy contributions to the single bond that are equivalent to those of methyl groups, -0.72457 eV (Eq. (14.151)), where the $N-H$ bonds are also energy matched to the $C-N$ bond.

The symbols of the functional groups of branched-chain secondary amines are given in Table 15.75. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of secondary amines are given in Tables $15.76,15.77$, and 15.78 , respectively. As in the case of $\mathrm{NH}_{2}$ (Eq. (13.339)), $C_{10}=2 C_{1}$ rather than $C_{1 o}=C_{1}$ in Eq. (15.61) for the $C-N$ bond. The total energy of each secondary amine given in Table 15.79 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.78 corresponding to functional-group composition of the molecule. The bond angle parameters of secondary amines determined using Eqs. (15.88-15.117) are given in Table 15.80. The color scale, translucent view of the charge-density of exemplary secondary amine, dimenthylamine, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.13.

Figure 15.13. (A)-(B) Color scale, translucent views of the charge-density of dimethylamine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## TERTIARY AMINES ( $\left.C_{n} H_{2 n+3} N, n=3,4,5 \ldots \infty\right)$

The tertiary amines, $C_{n} H_{2 n+3} N$, have three $C-N$ bonds to methyl or alkyl groups wherein $C-N$ comprises a functional group. The alkyl portion of the tertiary amine may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in tertiary amines are equivalent to those in branched-chain alkanes.

The $C-N$ group is solved by hybridizing the $2 s$ and $2 p$ AOs of the $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $N \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. In tertiary amines, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $N$ AO has an energy of $E(N)=-14.53414 \mathrm{eV}$. To meet the equipotential condition of the union of the $\mathrm{C}-\mathrm{N} \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $C-N$-bond MO given by Eq. (15.135) is $c_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to N$)=0.91140$.

As given in the Continuous-Chain Alkanes $\left(C_{n} H_{2 n+2}, n=3,4,5 \ldots \infty\right)$ section, the energy of each $C 2 s p^{3}$ HO must be a linear combination of that of the $\mathrm{CH}_{3}$ and $\mathrm{CH}_{2}$ groups that serve as basis elements. Each $\mathrm{CH}_{3}$ forms one $\mathrm{C}-\mathrm{C}$ bond, and each $\mathrm{CH}_{2}$ group forms two. Thus, the energy of each $\mathrm{C} 2 s p^{3} \mathrm{HO}$ of each $\mathrm{CH}_{3}$ and $\mathrm{CH}_{2}$ group alone is given by that in ethane, -0.72457 eV (Eq. (14.151)), and ethylene, -1.13379 eV (Eq. (14.511)), respectively. In order to match the energy of the component HOs and MOs for the entire molecule, the energy $E_{T_{\text {alkene }}}\left(C-C, 2 s p^{3}\right)$ given as a linear combination of these basis elements is -0.92918 eV (Eq. (14.513)). In tertiary amines, the $N$ binds to three $C 2 s p^{3}$ HOs and the corresponding $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of each $C-N$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $N$ atoms to the MO is -0.92918 eV . It comprises a linear combination of the energy for a primary amine, -0.72457 eV and a secondary amine, -1.13379 eV .

The symbols of the functional groups of branched-chain tertiary amines are given in Table 15.81. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of tertiary amines are given in Tables $15.82,15.83$, and 15.84 , respectively. The total energy of each tertiary amine given in Table 15.85 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.84 corresponding to functional-group composition of the molecule. The bond angle parameters of tertiary amines determined using Eqs. (15.88-15.117) are given in Table 15.86. The color scale, translucent view of the charge-density of exemplary tertiary amine, trimethylamine, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.14.

Figure 15.14. Color scale, translucent view of the charge-density of trimethylamine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (A) Top view. (B) Side view.

## ALDEHYDES ( $\left.C_{n} H_{2 n} O, \quad n=1,2,3,4,5 \ldots \infty\right)$

The alkyl aldehydes, $C_{n} H_{2 n} O$, each have a $H C=O$ moiety that comprises a $C=O$ functional group and a $C H$ functional group. The single bond of carbon to the carbonyl carbon atom, $C-C(O) H$, is a functional group. In addition to the $C=O$ functional group, formaldehyde comprises a $\mathrm{CH}_{2}$ functional group. The alkyl portion of the alkyl aldehyde may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in aldehydes are equivalent to those in branched-chain alkanes.

The CH functional group was solved in the Hydrogen Carbide $(\mathrm{CH})$ section except that $E_{\text {mag }}$ is not subtracted since unpaired electrons are not created with fragmentation of the CH functional group of aldehydes. The $\mathrm{CH}_{2}$ functional group of formaldehyde is solved in the Dihydrogen Carbide $\left(\mathrm{CH}_{2}\right)$ section except that the energy of each $\mathrm{C}-\mathrm{H}$ MO is matched to the initial energy of the $C 2 s p^{3}$ HO (Eq. (15.25)). The $C=O$ and $C-C(O) H$ groups are solved by hybridizing the $2 s$ and $2 p$ AOs of each $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3}$ HO and the $O \mathrm{AO}$ or between two $C 2 s p^{3} \mathrm{HOs}$, respectively, to form a MO permits each participating orbital to decrease in radius and energy. In alkyl aldehydes, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)) and the $O$ AO has an energy of $E(O)=-13.61806 \mathrm{eV}$. To meet the equipotential condition of the union of the $\mathrm{C}=\mathrm{O} \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $C=O$-bond MO given by Eq. (15.133) is $c_{2}\left(C 2 s p^{3} H O\right.$ to $\left.O\right)=0.85395$. The unpaired electrons created by bond breakage of the double $C=O$ bond requires that two times the $O 2 p$ AO magnetic energy $E_{\operatorname{mag}}$ (Eq. (15.69)) be subtracted from the total energy to give $E_{D}($ Group $)(\mathrm{eV})$ for $C=O$.
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C=O$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $O$ atoms to the MO is -2.69893 eV which is an energy minimum for the double bond between the pair of $C 2 s p^{3} \mathrm{HO}$ electrons of the $C$ atom and the pair of AO electrons of the $O$ atom. It is given as a linear combination of the energy contributions corresponding to a double bond, -1.13379 eV (Eq. (14.247)), and a triple bond, -1.56513 eV (Eq. (14.342)). The triple bond contribution includes the $C 2 s p^{3} \mathrm{HO}$ electron of the $C-H$ bond in addition to the pair involved directly in the double bond with $O$. $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-C(O) H$ group is equivalent to that of an alkane, -1.85836 eV , where both energy contributions are given by Eq. (14.513). It is based on the energy match between the $C 2 s p^{3} \mathrm{HOs}$ of the aldehyde. In order to match energy between the groups bonded to the $C=O$, electron-density is shared. Due to the interaction in the transition state between the groups based on the sharing, $C_{1 o}=2 C_{1}$ rather than $C_{1 o}=C_{1}$ in Eq. (15.61) for the $C-C(O) H$ bond.

The symbols of the functional groups of alkyl aldehydes are given in Table 15.87. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl aldehydes are given in Tables $15.88,15.89$, and 15.90 , respectively. The total energy of each alkyl aldehyde given in Table 15.91 was calculated as the sum over the integer multiple of each $E_{D}\left(G_{r o u p}\right)$ of Table 15.90 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl aldehydes determined using Eqs. (15.88-15.117) are given in Table 15.92. The color scale, translucent view of the charge-density of exemplary aldehyde, Propanal, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.15.

Figure 15.15. (A)-(B) Color scale, translucent views of the charge-density of propanal showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.87. The symbols of functional groups of alkyl aldehydes.

KETONES ( $\left.C_{n} H_{2 n} O, n=1,2,3,4,5 \ldots \infty\right)$
The alkyl ketones, $C_{n} H_{2 n} O$, each have a $C=O$ moiety that comprises a functional group. Each of the two single bonds of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. The alkyl portion of the alkyl ketone may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in ketones are equivalent to those in branched-chain alkanes.

The $C=O$ and $C-C(O)$ groups are solved by hybridizing the $2 s$ and $2 p$ AOs of each $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $O \mathrm{AO}$ or between two $C 2 s p^{3}$ HOs, respectively, to form a MO permits each participating orbital to decrease in radius and energy. In alkyl ketones, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)) and the $O$ AO has an energy of $E(O)=-13.61806 \mathrm{eV}$. To meet the equipotential condition of the union of the $C=O \mathrm{H}_{2}-$ type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $C=O$-bond MO given by Eq. (15.133) is $c_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to $\left.O\right)=0.85395$. The unpaired electrons created by bond breakage of the double $C=O$ bond requires that two times the $O 2 p$ AO magnetic energy $E_{\text {mag }}$ (Eq. (15.69)) be subtracted from the total energy to give $E_{D}(G r o u p)(e V)$ for $C=O$.

As in the case with aldehydes, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C=O$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $O$ atoms to the MO is -2.69893 eV which is an energy minimum for the double bond between the pair of $C 2 s p^{3} \mathrm{HO}$ electrons of the $C$ atom and the pair of AO electrons of the $O$ atom. It is given as a linear combination of the energy contributions corresponding to a double bond, -1.13379 eV (Eq. (14.247)), and a triple bond, -1.56513 eV (Eq. (14.342)). The triple bond contribution includes the $C 2 s p^{3} \mathrm{HO}$ electron of the $C-C(O)$ bond in addition to the pair involved directly in the double bond with $O$. Consequently, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-C(O)$-bond MO is -1.44915 eV , corresponding to the energy contributions of the two $C 2 s p^{3}$ HOs to the single bond that are equivalent to those of methyl groups, -0.72457 eV (Eq. (14.151)). Since there are two $C-C(O)$ bonds in ketones versus one in aldehydes, $C_{1 o}=C_{1}$ in Eq. (15.61) for each $C-C(O)$ ketone bond.

The symbols of the functional groups of alkyl ketones are given in Table 15.93. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.64)) parameters of alkyl ketones are given in Tables $15.94,15.95$, and 15.96 , respectively. The total energy of each alkyl ketone given in Table 15.97 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.96 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C 2 s p^{3} \mathrm{HO}$ magnetic energy $E_{\operatorname{mag}}$ that is subtracted from the weighted sum of the $E_{D}($ Group $)(e V)$ values based on composition is given by Eq. (15.67). The bond angle parameters of alkyl ketones determined using Eqs. (15.88-15.117) are given in Table 15.98. The color scale, translucent view of the charge-density of exemplary ketone, methyl ethyl ketone, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.16.

Figure 15.16. (A)-(B) Color scale, translucent views of the charge-density of methyl ethyl ketone showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## CARBOXYLIC ACIDS ( $\left.C_{n} H_{2 n} O_{2}, n=1,2,3,4,5 \ldots \infty\right)$

The alkyl carboxylic acids, $\mathrm{C}_{n} \mathrm{H}_{2 n} \mathrm{O}_{2}$, comprise a $\mathrm{C}=\mathrm{O}$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. Formic acid has a $H C=O$ moiety that comprises a more stable $C=O$ functional group and a CH functional group. All carboxylic acids further comprise a $\mathrm{C}-\mathrm{OH}$ moiety that comprises $\mathrm{C}-\mathrm{O}$ and OH functional groups. The alkyl portion of the alkyl carboxylic acid may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in carboxylic acids are equivalent to those in branched-chain alkanes.

The CH functional group was solved in the Hydrogen Carbide $(\mathrm{CH}$ ) section except that the energy of the $C-H \mathrm{MO}$ is matched to the carbon-atom contribution to $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}(\mathrm{AO} / \mathrm{HO})$ and $E_{T}\left(\right.$ atom-atom,msp $\left.{ }^{3} . A O\right)$ of the $C-O$ group. The alkyl carboxylic acid $C=O$ and $C-C(O)$ groups are equivalent to those given in the Aldehydes section except that $\bar{E}_{\text {Kvib }}$ is that of a carboxylic acid, and $C-C(O)$ is equivalent to the n -alkane $C-C$ bond group in the case of conjugated carbonyls wherein the alkene groups when present such as the $C=C$ group are equivalent to those of the corresponding alkene. The formic acid $C=O$ group is solved equivalently to that of the alkyl carboxylic acid group, except that $\Delta E_{H_{2} \mathrm{MO}}(A O / \mathrm{HO})$ and $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . A O\right)$ correspond to a $25 \%$ increase in the donation of charge density from the orbitals of the atoms to the $C=O$ MO due to the presence of a $H$ bound to the carbonyl carbon. Also, $\bar{E}_{K v i b}$ is that corresponding to formic acid. The $C-O$ and $O H$ groups are equivalent to those of alkyl alcohols given in the corresponding section except that the energy of the $C-O \mathrm{MO}$ is matched to that of the $C=O$ group and $\bar{E}_{\text {Kvib }}$ is that of a carboxylic acid. $\Delta E_{\mathrm{H}_{2} M O}(A O / H O)$ of the $C-O$ group is equal to $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the alkyl $C=O$ group in order to match the energies of the corresponding MOs.

As in the case with aldehydes and ketones, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C=O$-bond MO in Eq. (15.61) of alkyl carboxylic acids due to the charge donation from the $C$ and $O$ atoms to the MO is -2.69893 eV which is an energy minimum for the double bond between the pair of $C 2 s p^{3} \mathrm{HO}$ electrons of the $C$ atom and the pair of AO electrons of the carbonyl $O$ atom. It is given as a linear combination of the energy contributions corresponding to a double bond, -1.13379 eV (Eq. (14.247)), and a triple bond, -1.56513 eV (Eq. (14.342)). The triple bond contribution includes the energy match of the carbonyl $C 2 s p^{3} \mathrm{HO}$ electron with the $O$ of the $C-O$-bond MO in addition to the pair involved directly in the double bond with the carbonyl $O$.
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the formic acid $C=O$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $O$ atoms to the MO is -3.58557 eV . This is also an energy minimum for the double bond between the pair of $C 2 s p^{3} \mathrm{HO}$ electrons of the $C$ atom and the pair of AO electrons of the carbonyl $O$ atom. It is given as a linear combination of the energy contributions corresponding to a triple bond, -1.56513 eV (Eq. (14.342)), and a quadruple bond, -2.02043 eV (Eqs. (15.1815.21 ) with $s=4)$ ) where the bond order components are increased by an integer over that of alkyl carboxylic acids due to the presence of a $H$ bound to the carbonyl carbon.
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the carboxylic acid $C-C(O)$ group is equivalent to that of alkanes and aldehydes, -1.85836 eV , where both energy contributions are given by Eq. (14.513). It is based on the energy match between the $C 2 s p^{3}$ HOs of the carboxylic acid. As in the case of aldehydes, $C_{1 o}=2 C_{1}$ in Eq. (15.52).
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the carboxylic acid $C-O$ group is equivalent to that of alkyl alcohols, -1.85836 eV . It is based on the energy match between the $O \mathrm{AO}$ and the $C 2 s p^{3} \mathrm{HO}$ of a methylene group (the maximum hybridization for a single bond) where both energy contributions are given by Eq. (14.513). $E_{T}$ (atom-atom, msp ${ }^{3} . A O$ ) of the $C-O$ group matches that of the $C-C(O)$ group.

The symbols of the functional groups of alkyl carboxylic acids are given in Table 15.99. The geometrical (Eqs. (15.115.5 ) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl carboxylic acids are given in Tables $15.100,15.101$, and 15.102 , respectively. The total energy of each alkyl carboxylic acid given in Table 15.103 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.102 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C 2 s p^{3} \mathrm{HO}$ magnetic energy $E_{\text {mag }}$ that is subtracted from the weighted sum of the $E_{D}(G r o u p)(e V)$ values based on composition is given by Eq. (15.67). The bond angle parameters of alkyl carboxylic acids determined using Eqs. (15.79-15.108) are given in Table
15.104. The color scale, translucent view of the charge-density of exemplary carboxylic acid, Propanoic acid, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.17.

Figure 15.17. (A)-(B) Color scale, translucent views of the charge-density of propanoic acid showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## CARBOXYLIC ACID ESTERS ( $\left.C_{n} H_{2 n} O_{2}, n=1,2,3,4,5 \ldots \infty\right)$

The alkyl carboxylic acid esters, $C_{n} H_{2 n} O_{2}$, comprise a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. Formic acid ester has a $H C=O$ moiety that comprises a more stable $C=O$ functional group and a CH functional group. All carboxylic acid esters further comprise a $C O R$ moiety that comprises a $\mathrm{C}-\mathrm{O}$ functional group and three types of $O-R$ functional groups, one for $R$ comprising methyl, one for $R$ comprising an alkyl ester group of a formate, and one for $R$ comprising an alkyl ester group of an alkyl carboxylate. The alkyl portion of the alkyl carboxylic acid ester may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $\mathrm{C}-\mathrm{C}$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in carboxylic acid esters are equivalent to those in branched-chain alkanes

The $C H$ functional group is equivalent to that of formic acid. The alkyl carboxylic acid ester $C=O$ and $C-C(O)$ groups are equivalent to those given in the Carboxylic Acids section. The formic acid ester $C=O$ group is equivalent to that given in the Carboxylic Acids section except that $\bar{E}_{\text {Kvib }}$ is that corresponding to a formic acid ester. The $C-O$ group is equivalent to that given in the Carboxylic Acids section except that the parameters corresponding to oscillation of the bond in the transition state, $\bar{E}_{D}(e V)$ and $\bar{E}_{K v i b}$, are those of a carboxylic acid ester. As in the case with the alkyl ethers, each $O-C$ group is solved by hybridizing the $2 s$ and $2 p$ AOs of the $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $O \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. To meet the equipotential condition of the union of the $\mathrm{O}-\mathrm{CH} \mathrm{H}_{2}$-type-ellipsoidal-MO with other orbitals of the molecule, the hybridization factor $c_{2}$ of Eq. (15.60) for the $O-C$-bond MO given by Eq. (15.133) is: $c_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to $\left.O\right)=0.85395$.
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ (Eq. (15.61)) of (1) the $C=O$ group of alkyl carboxylic acid esters, (2) the $C=O$ group of formic acid esters, (3) the alkyl carboxylic acid ester $C-C(O)$ group, and (4) the carboxylic acid ester $C-O$ group are equivalent to those of the corresponding carboxylic acids. The values given in the Carboxylic Acids section are -2.69893 eV , $-3.58557 \mathrm{eV},-1.85836 \mathrm{eV}$, and -1.85836 eV , respectively. $E_{T}\left(\right.$ atom - atom, $\left.\mathrm{msp}^{3} . A O\right)$ of the $C-O$ group matches that of the $C-C(O)$ group. Also, as in the case of aldehydes, $C_{1 o}=2 C_{1}$ in Eq. (15.61) for the $C-C(O)$ group.
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $O-C$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $O$ atoms to the MO is -1.13379 eV for the $\mathrm{O}-\mathrm{CH}_{3}$ group of formate and alkyl carboxylates, -1.44915 eV for the $\mathrm{O}-\mathrm{R}$ group of alkyl carboxylates, and -1.85836 eV for the $O-R$ group of alkyl formates, where $R$ is an alkyl group. Each is based on the energy match between the $O$ AO, initially at the Coulomb potential of a proton and an electron (Eqs. (1.257) and (10.162), respectively), the $C 2 s p^{3} \mathrm{HO}$ of the methyl or alkyl ester group, and the carbonyl carbon. The increasing energy contributions to the single bond correspond to the increasing hybridization of linear combinations of increasing bond order. The energy contributions corresponding to one half of a double bond and those of the methyl-methyl and methylene-methylene bonds are -1.13379 eV (Eq. (14.247)), two times -0.72457 eV (Eq. (14.151)), and two times -0.92918 eV (Eq. (14.513)), respectively.

The symbols of the functional groups of alkyl carboxylic acid esters are given in Table 15.105. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl carboxylic acid esters are given in Tables $15.106,15.107$, and 15.108 , respectively. The total energy of each alkyl carboxylic acid ester given in Table 15.109 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.108 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage , the $C 2 s p^{3} \mathrm{HO}$ magnetic energy $E_{\text {mag }}$ that is subtracted from the weighted sum of the $E_{D}($ Group $)(\mathrm{eV})$ values based on composition is given by Eq. (15.67). The bond angle parameters of alkyl carboxylic acid esters determined using Eqs. (15.8815.117) are given in Table 15.110. The color scale, translucent view of the charge-density of exemplary carboxylic acid ester, methyl acetate, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.18.

Figure 15.18. Color scale, translucent view of the charge-density of methyl acetate showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.105. The symbols of functional groups of alkyl carboxylic acid esters.

| Functional Group | Group Symbol |
| :---: | :---: |
| CH (formic acid ester) group | $C-H$ (i) |
| C-C(O) | $C-C(O)$ |
| $C=O$ (formic acid ester) | $C=O$ (i) |
| $C=O$ (alkyl carboxylic acid ester) | $C=O$ (ii) |
| (O) $\mathrm{C}-\mathrm{O}$ | C-O |
| $\mathrm{O}-\mathrm{CH}_{3}$ | $O-C$ (i) |
| $O-R$ (formic acid ester) | $O-C$ (ii) |
| $O-R$ (alkyl acid ester) | $O-C$ (iii) |
| OH group | OH |
| $\mathrm{CH}_{3}$ group | $\mathrm{C}-\mathrm{H}\left(\mathrm{CH}_{3}\right)$ |
| $\mathrm{CH}_{2}$ group | $\mathrm{C}-\mathrm{H}\left(\mathrm{CH}_{2}\right)$ |
| CH (alkyl) group | $C-H$ (ii) |
| $C C$ bond ( $n-C$ ) | $C-C$ (a) |
| $C C$ bond (iso-C) | $C-C$ (b) |
| $C C$ bond (tert-C) | $C-C$ (c) |
| $C C$ (iso to iso-C) | $C-C$ (d) |
| $C C$ ( $t$ to $t$ - $C$ ) | $C-C$ (e) |
| $\underline{C C}(t$ to iso-C) | $C-C$ (f) |

## AMIDES ( $\left.C_{n} H_{2 n+1} N O, n=1,2,3,4,5 \ldots \infty\right)$

The alkyl amides, $C_{n} H_{2 n+1} N O$, comprise a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. Formamide has a $H C=O$ moiety that comprises a more stable $C=O$ functional group and a CH functional group that is equivalent to that of the $C H$ (i) of aldehydes given in the corresponding section. It is also equivalent to that of the iso- CH group of branched-chain-alkyl portion of the alkyl amide except that $E_{\text {mag }}$ (Eq. (15.47)) is not subtracted from $E_{D}($ Group $)$. All amides further comprise a $\mathrm{C}-\mathrm{NH}_{2}$ moiety that comprises a $\mathrm{NH}_{2}$ functional group and two types of $C-N$ functional groups, one for formamide and the other for alkyl amides $\left(R C(O) N H_{2}\right.$ where $R$ is alkyl). The alkyl portion of the alkyl amide may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $\mathrm{C}-\mathrm{C}$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in amides are equivalent to those in branched-chain alkanes.

The $\mathrm{NH}_{2}$ functional group was solved in the Dihydrogen Nitride $\left(\mathrm{NH}_{2}\right)$ section except that the energy of the $\mathrm{N}-\mathrm{H}$
MO is matched to the nitrogen-atom contribution to $\Delta E_{H_{2} M O}(A O / H O)$ and $E_{T}\left(\right.$ atom-atom, msp $\left.{ }^{3} \cdot A O\right)$ of the $C-N$ group. Both alkyl amide $C=O$ groups and the $C-C(O)$ group are equivalent to those given in the Carboxylic Acid Esters section except that $\bar{E}_{K v i b}$ of the $C-C(O)$ group is matched to that of an amide. The $C-N$ groups are equivalent to those of alkyl amines given in the corresponding section except that the energy of the $C-N$ MO is matched to that of the $C=O$ group and $\bar{E}_{\text {Kvib }}$ is that of a amide. $\Delta E_{H_{2} M O}(A O / H O)$ of the $C-N$ group is equal to $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} \cdot A O\right)$ of the alkyl $C=O$ and $C-N$ groups in order to match the energies of the corresponding MOs.

As in the case of primary amines, each $C-N$ group is solved by hybridizing the $2 s$ and $2 p$ AOs of the $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $N \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. To meet the equipotential condition of the union of the $\mathrm{C}-\mathrm{N} \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with other orbitals of the molecule, the hybridization factor $c_{2}$ of Eq. (15.52) for the $C-N$-bond MO given by Eq. (15.133) is $c_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to $\left.N\right)=0.91140$.
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ (Eq. (15.52)) of the $C=O$ group of alkyl amides and the $C=O$ group of formamide are equivalent to those of the corresponding carboxylic acids and esters. The values given in the Carboxylic Acids section are -2.69893 eV and -3.58557 eV , respectively.
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the amide $C-C(O)$ group is the same as alkanes, aldehydes, carboxylic acids, and carboxylic acid esters, -1.85836 eV , where both energy contributions are given by Eq. (14.513). Also, as in the case of aldehydes, $C_{1 o}=2 C_{1}$ in Eq. (15.61).

In order to match energy throughout the chain of the amide molecule, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-N$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $N$ atoms to the MO is -1.65376 eV . It is based on the energy match between the $C 2 s p^{3} \mathrm{HO}$ of the carbonyl and the primary amino group $\mathrm{NH}_{2}$. It is given by the linear combination of -0.92918 eV (Eq. (14.513)) which matches the contiguous $C-C(O)$ or $H C(O)$ group and -0.72457 eV (Eq. (14.151)), the contribution of a primary amino group given in the Primary Amines section.

The symbols of the functional groups of alkyl amides are given in Table 15.111. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl amides are given in Tables $15.112,15.113$, and 15.114 , respectively. The total energy of each alkyl amide given in Table 15.115 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.114 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl amides determined using Eqs. (15.88-15.117) are given in Table 15.116. The color scale, translucent view of the charge-density of exemplary amide, propionamide, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.19.

Figure 15.19. (A)-(B) Color scale, translucent views of the charge-density of propionamide showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.116. The bond angle parameters of alkyl amides and experimental values [1]. In the calculation of $\theta_{v}$, the parameters from the preceding angle were used.

## N-ALKYL AND N,N-DIALKYL-AMIDES ( $\left.C_{n} H_{2 n+1} N O, n=2,3,4,5 \ldots \infty\right)$

The N-alkyl and N,N-dialkyl amides, $C_{n} H_{2 n+1} N O$, comprise a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. Formamide has a $H C=O$ moiety that comprises a more stable $C=O$ functional group and a CH functional group that is equivalent to that of the iso- CH group of branched-chain-alkyl portion of the N -alkyl or $\mathrm{N}, \mathrm{N}$-dialkyl amide. All amides further comprise a $\mathrm{C}-N\left(R_{1}\right) R_{2}$ moiety that comprises two types of $C-N$ functional groups, one for formamide and the other for alkyl amides $\left(R C(O) N\left(R_{1}\right) R_{2}\right.$ where $R$ is alkyl). The N or $\mathrm{N}, \mathrm{N}-$ dialkyl moiety comprises three additional groups depending on the alkyl substitution of the nitrogen. In the case of a single methyl or alkyl substitution, the $\mathrm{NH}-\mathrm{C}$ bond and NH are functional groups, and the $N-C$ bond of a di-substituted nitrogen is the third.

The alkyl portion of the N -alkyl or $\mathrm{N}, \mathrm{N}$-dialkyl amide may comprise at least two terminal methyl groups ( $\mathrm{CH}_{3}$ ) at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carboncarbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and tbutyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in N -alkyl or $\mathrm{N}, \mathrm{N}$-dialkyl amides are equivalent to those in branched-chain alkanes.

The $N H$ functional group was solved in the Hydrogen Nitride $(N H)$ section except that the energy of the $N-H$ MO is matched to the nitrogen-atom contribution to $\Delta E_{H_{2} M O}(A O / H O)$ and $E_{T}\left(\right.$ atom-atom, msp $\left.{ }^{3} \cdot A O\right)$ of the $C-N$ group. The $C-C(O)$ group, both N -alkyl or $\mathrm{N}, \mathrm{N}$-dialkyl amide $C=O$ groups, and both $C-N$ groups are equivalent to those given in the Amides section.

As in the case of primary amines, each $N-C$ group is solved by hybridizing the $2 s$ and $2 p$ AOs of the $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $N \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. To meet the equipotential condition of the union of the $\mathrm{N}-\mathrm{C} \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with other orbitals of the molecule, the hybridization factor $c_{2}$ of Eq. (15.61) for the $\mathrm{N}-\mathrm{C}$ bond MO given by Eq. (15.133) is $c_{2}\left(C 2 s p^{3} H O\right.$ to $\left.N\right)=0.91140$.
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the N -substituted amide $C-C(O)$ group is the same as alkanes, aldehydes, carboxylic acids, carboxylic acid esters, and amides, -1.85836 eV , where both energy contributions are given by Eq. (14.513). Also, as in the case of aldehydes, $C_{1 o}=2 C_{1}$ in Eq. (15.61).
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ (Eq. (15.61)) of the $C=O$ group of N -substituted alkyl amides and the $C=O$ group of Nsubstituted formamide are equivalent to those of the corresponding carboxylic acids, carboxylic esters, and amides. The values given in the Carboxylic Acids section are -2.69893 eV and -3.58557 eV , respectively.
$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of both $C-N$ functional groups are the same as those of the corresponding groups of amides, $-1.65376 \mathrm{eV} . E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)$ of the singly-substituted $\mathrm{NH}-\mathrm{C}$-bond MO in Eq. (15.61) due to the charge donation from the $N$ and $C$ atoms to the MO is -0.92918 eV . It is equivalent to that of tertiary amines and matches the energy of the $N H-C$ group to that of the $C-N$ group wherein $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the latter is a linear combination of -0.92918 eV (Eq. (14.513)) and -0.72457 eV (Eq. (14.151)). $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the doubly-substituted $N-C$ bond MO is -0.72457 eV . It is equivalent to that of the contribution of each atom of a primary amine and also matches the energy of the $N-C$ group to that of the $C-N$ group by matching one of the components of $E_{T}\left(\right.$ atom-atom,msp $\left.{ }^{3} . A O\right)$ of the latter.

The symbols of the functional groups of N -alkyl and $\mathrm{N}, \mathrm{N}$-dialkyl amides are given in Table 15.117. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of Nalkyl and $\mathrm{N}, \mathrm{N}$-dialkyl amides are given in Tables $15.118,15.119$, and 15.120 , respectively. The total energy of each N -alkyl or $\mathrm{N}, \mathrm{N}$-dialkyl amide given in Table 15.121 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.120 corresponding to functional-group composition of the molecule. The bond angle parameters of N -alkyl and $\mathrm{N}, \mathrm{N}$-dialkyl amides determined using Eqs. (15.79-15.108) are given in Table 15.122. The color scale, translucent view of the charge-density of exemplary alkyl-amide, N,N-dimethylacetamide, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.20.

Figure 15.20. Color scale, translucent view of the charge-density of $\mathrm{N}, \mathrm{N}$-dimethylacetamide showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## UREA ( $\mathrm{CH}_{4} \mathrm{~N}_{2} \mathrm{O}$ )

Urea, $\mathrm{CH}_{4} \mathrm{~N}_{2} \mathrm{O}$, comprises a $\mathrm{C}=\mathrm{O}$ functional group and two $\mathrm{C}-\mathrm{NH}_{2}$ moieties that each comprise a $\mathrm{NH}_{2}$ functional group and a $C-N$ functional group. The $C=O$ group is equivalent to that given for formamide in the Amides section except that the energy terms due to oscillation in the transition state are matched to that of urea. The $\mathrm{NH}_{2}$ and $\mathrm{C}-\mathrm{N}$ functional groups are also equivalent to those given in the Amides section. $E_{T}\left(\right.$ atom-atom, $m s p^{3} . A O$ ) (Eq. (15.61)) of the $C=O$ and $C-N$ groups are equivalent to those of formamide. The values given in the Amides section are -3.58557 eV , and -1.65376 eV , respectively.

The symbols of the functional groups of urea are given in Table 15.123. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of urea are given in Tables 15.124, 15.125 , and 15.126 , respectively. The total energy of urea given in Table 15.127 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.126 corresponding to functional-group composition of the molecule. The bond angle parameters of urea determined using Eqs. $(15.88-15.117)$ are given in Table 15.128. The color scale, translucent view of the charge-density of urea comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.21.

Figure 15.21. Color scale, translucent view of the charge-density of urea showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## CARBOXYLIC ACID HALIDES ( $\left.C_{n} H_{2 n-1} O X, X=F, C l, B r, I ; n=1,2,3,4,5 \ldots \infty\right)$

The alkyl carboxylic acid halides, $C_{n} H_{2 n-1} O X$, comprise a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. All carboxylic acid halides further comprise a $C-X$ functional group where $X$ is a halogen atom. The alkyl portion of the alkyl carboxylic acid halide may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straightchain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in carboxylic acids are equivalent to those in branched-chain alkanes.

The alkyl carboxylic acid halide $C=O$ and $C-C(O)$ groups are equivalent to those given in the Aldehydes section and the Ketones section, respectively. The values of $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ given in these sections are -2.69893 eV and -1.44915 eV , respectively.

As in the case of alkyl halides, each $(O) C-X$ group is solved by hybridizing the $2 s$ and $2 p$ AOs of the $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $X$ AO to form a MO permits each participating orbital to decrease in radius and energy. For example, to meet the equipotential condition of the union of the O$) \mathrm{C}-\mathrm{Cl} \mathrm{H} \mathrm{H}_{2}$-type-ellipsoidal-MO with other orbitals of the molecule, the hybridization factor $\mathrm{C}_{2}$ of Eq. (15.61) for the $(O) C-C l$-bond MO given by Eq. (15.130) is $C_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to Cl$)=0.81317$. The solution is equivalent to that of the alkyl chloride bond except that the energy parameters corresponding to oscillation in the transition state are matched to those of a carboxylic acid chloride.

As in the case with the $C-C l$ group of alkyl chlorides, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $(O) C-C l$-bond MO in Eq. (15.61) of alkyl carboxylic acid chlorides due to the charge donation from the $C$ and Cl atoms to the MO is -1.44915 eV where both energy contributions are given by Eq. (14.511). This matches the energy of the $C-C(O)$ functional group with that of the $(O) C-C l$ group within the carboxylic acid chloride molecule.

The symbols of the functional groups of alkyl carboxylic acid chlorides are given in Table 15.129. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl carboxylic acid chlorides are given in Tables $15.130,15.131$, and 15.132 , respectively. The total energy of each alkyl carboxylic acid chloride given in Table 15.133 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.132 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl carboxylic acid chlorides determined using Eqs. (15.88-15.117) are given in Table 15.134. The color scale, translucent view of the charge-density of exemplary carboxylic acid halide, acetyl chloride, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.22.

## CARBOXYLIC ACID ANHYDRIDES ( $\left.C_{n} H_{2 n-2} O_{3}, n=2,3,4,5 \ldots \infty\right)$

The alkyl carboxylic acid anhydrides, $\mathrm{C}_{n} \mathrm{H}_{2 n-2} \mathrm{O}_{3}$, have two $(\mathrm{O}) \mathrm{C}-\mathrm{O}$ moieties that each comprise $\mathrm{C}=\mathrm{O}$ and $\mathrm{C}-\mathrm{O}$ functional groups. The single bond of carbon to the carbonyl carbon atom, $\mathrm{C}-\mathrm{C}(\mathrm{O})$, is also a functional group. The alkyl portion of the alkyl carboxylic acid anhydride may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n -alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in carboxylic acid anhydrides are equivalent to those in branched-chain alkanes.

The alkyl carboxylic acid anhydride $C=O$ and $C-C(O)$ groups are equivalent to those given in the Carboxylic Acid Esters section and the Ketones section, respectively. The values of $E_{T}\left(\right.$ atom-atom, msp $\left.{ }^{3} . A O\right)$ given in these sections are -2.69893 eV and -1.44915 eV , respectively. The $C-O$ group is also equivalent to that given in the Carboxylic Acid Esters section except that $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is equivalent to that of an alkyl ether as given in the corresponding section and the energy terms due to oscillation in the transition state are matched to that of a carboxylic acid anhydride.

For the $C-O$ group, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -1.65376 eV . It is based on the energy match between the $O$ AO and the $C 2 s p^{3} \mathrm{HO}$ of each $C-C(O)$ group and is given by the linear combination of -0.72457 eV (Eq. (14.151)) and -0.92918 eV (Eq. (14.513)), respectively. This matches -0.72457 eV , the energy contribution of each of the $C 2 s p^{3}$ HOs to each $C-C(O)$ functional group, with that of the corresponding energy component of the $C-O$ group and gives a minimum energy within the carboxylic acid anhydride molecule.

The symbols of the functional groups of alkyl carboxylic acid anhydrides are given in Table 15.135. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl carboxylic acid anhydrides are given in Tables 15.136, 15.137, and 15.138, respectively. The total energy of each alkyl carboxylic acid anhydride given in Table 15.139 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.138 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl carboxylic acid anhydrides determined using Eqs. (15.88-15.117) are given in Table 15.140. The color scale, translucent view of the chargedensity of exemplary carboxylic acid anhydride, acetic anhydride, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.23.

Figure 15.23. (A)-(B), color scale, translucent views of the charge-density of acetic anhydride showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## NITRILES ( $\left.C_{n} H_{2 n-1} N, n=2,3,4,5 \ldots \infty\right)$

The nitriles, $C_{n} H_{2 n-1} N$, comprise a $C \equiv N$ functional group, and the single bond of carbon to the nitrile carbon atom, $C-C N$, is also a functional group. The alkyl portion of the nitrile may comprise at least two terminal methyl groups ( $\mathrm{CH}_{3}$ ) at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carboncarbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and tbutyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in nitriles are equivalent to those in branched-chain alkanes.

The nitrile $C \equiv N$ is solved equivalently to acetylene as given in the Acetylene Molecule section except that the energy for $E\left(\begin{array}{l}\text { оо/но }\end{array}\right)$ is two times that given in Eq. (14.343), 16.20002 eV , in order to match the $N$ AOs to that of the nitrile $C 2 s p^{3} \mathrm{HO}$ having a bond order of three. $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C \equiv N$ functional group is -1.56513 eV (Eq. (14.342)) corresponding to the third-order bonded $C 2 s p^{3} \mathrm{HO}$.

The $C-C N$ functional group is equivalent to that of an alkyl $C-C$ group given in the Continuous-Chain Alkanes section except that $E_{T}\left(\mathrm{H}_{2} M O\right)$ and $\bar{E}_{K v i b}$ are those corresponding to a nitrile. As given in the Continuous-Chain Alkanes section, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the alkyl $C-C$ group is -1.85836 eV where both energy contributions are given by Eq. (14.513). It is based on energy matching within the nitrile. It corresponds to the maximum-magnitude energy contributions of a single-bonded and a third-order bonded $C 2 s p^{3} \mathrm{HO}$.

The symbols of the functional groups of nitriles are given in Table 15.141. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of nitriles are given in Tables $15.142,15.143$, and 15.144 , respectively. The total energy of each nitrile given in Table 15.139 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.144 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C 2 s p^{3} \mathrm{HO}$ magnetic energy $E_{\text {mag }}$ that is subtracted from the weighted sum of the $E_{D}($ Group $)(e V)$ values based on composition is given by Eq. (15.67). The bond angle parameters of nitriles determined using Eqs. (15.88-15.117) are given in Table 15.146. The $C$ of the $C \equiv N$ group can further bond with only one atom, and the bond is linear as a minimum of energy as in the case of acetylene and alkynes. The color scale, translucent view of the charge-density of exemplary nitrile, propanenitrile, comprising the concentric shells of atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.24.

Figure 15.24. Color scale, translucent view of the charge-density of propanenitrile showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.146. The bond angle parameters of nitriles and experimental values [1]. In the calculation of $\theta_{v}$, the parameters from the preceding angle were used. $E_{T}$ is

THIOLS ( $\left.C_{n} H_{2 n+2} S_{m}, \quad n=1,2,3,4,5 \ldots \infty\right)$
The alkyl thiols, $C_{n} H_{2 n+2} S_{m}$, comprise a $S H$ functional group and a $C-S$ functional group. The alkyl portion of the alkyl thiol may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n -alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in thiols are equivalent to those in branched-chain alkanes.

The parameters of the $S H$ functional group is solved using Eq. (15.41). As in the case of the $C-H$ bonds of $C H_{n} n=1,2,3$, the $S-H$-bond MO is a partial prolate spheroid in between the sulfur and hydrogen nuclei and is continuous with the $S 3 p$ shell. The energy of the $H_{2}$-type ellipsoidal MO is matched to that of the $S 3 p$ shell and comprises $75 \%$ of a $H_{2}$-type ellipsoidal MO in order to match potential, kinetic, and orbital energy relationships. Since the energy of $S$, $E(S)=-10.36001 \mathrm{eV}$, is less that that of $H$, the linear combination of the $H_{2}$-type ellipsoidal MO with the $S 3 p$ shell further comprises an excess $50 \%$ charge-density donation from $H$ to the $S 3 p$ shell of the $S-H$-bond MO to achieve an energy minimum. The initial total energy of the shell is given by the sum over the four $3 p$ electrons. From Eq. (15.12), the sum $E_{T}(S, 3 p)$ of the energies of $S, S^{+}, S^{2+}$, and $S^{3+}[38]$ is:

$$
\begin{equation*}
E_{T}(S, 3 p)=10.36001 \mathrm{eV}+23.33788 \mathrm{eV}+34.79 \mathrm{eV}+47.222 \mathrm{eV}=115.70989 \mathrm{eV} \tag{15.137}
\end{equation*}
$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius $r_{3 p}$ of the $S 3 p$ shell may be calculated from the Coulombic energy using Eqs. (15.13) and (15.137).

$$
\begin{equation*}
r_{3 p}=\sum_{q=12}^{15} \frac{(Z-q) e^{2}}{8 \pi \varepsilon_{0}(e 115.70989 \mathrm{eV})}=\frac{10 e^{2}}{8 \pi \varepsilon_{0}(\mathrm{e} 115.70989 \mathrm{eV})}=1.17585 a_{0} \tag{15.138}
\end{equation*}
$$

where $Z=16$ for sulfur. Using Eqs. (15.14) and (15.138), the Coulombic energy $E_{\text {Coulomb }}(S, 3 p)$ of the outer electron of the $S 3 p$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}(S, 3 p)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 p}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.17585 a_{0}}=-11.57099 \mathrm{eV} \tag{15.139}
\end{equation*}
$$

The sharing of the electrons between the $S$ and $H$ atoms permits the formation an $S-H$-bond MO that is lowered more in energy than the participating $S 3 p$ orbital which consequently increases in energy. By considering the $50 \%$ electron redistribution in the $S-H$ group as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{S-H 3 p}$ of the $S 3 p$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$
\begin{equation*}
r_{S-H 3 p}=\left(\sum_{n=12}^{15}(Z-n)+2(0.25)\right) \frac{e^{2}}{8 \pi \varepsilon_{0}(e 115.70989 \mathrm{eV})}=\frac{10.5 e^{2}}{8 \pi \varepsilon_{0}(e 115.70989 \mathrm{eV})}=1.23465 a_{0} \tag{15.140}
\end{equation*}
$$

where the $s=-2$ in Eq. (15.18) due to the charge donation from $H$ to $S$. Using Eqs. (15.19) and (15.121), the Coulombic energy $E_{\text {Coulomb }}\left(S_{S-H}, 3 p\right)$ of the outer electron of the $S 3 p$ shell is:

$$
\begin{equation*}
E_{\text {Coulomb }}\left(S_{S-H}, 3 p\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{S-H 3 p}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.23465 a_{0}}=-11.01999 \mathrm{eV} \tag{15.141}
\end{equation*}
$$

Thus, $E_{T}(S-H, 3 p)$, the energy change of each $S 3 p$ shell with the formation of the $S-H$-bond MO is given by the difference between Eq. (15.139) and Eq. (15.141):

$$
\begin{equation*}
E_{T}(S-H, 3 p)=E\left(S_{S-H}, 3 p\right)-E(S, 3 p)=-11.01999 \mathrm{eV}-(-11.57099 \mathrm{eV})=0.55100 \mathrm{eV} \tag{15.142}
\end{equation*}
$$

Then, in Eq. (15.51):

$$
\begin{equation*}
E_{T}(A O / H O)=E(S)-E_{T}(S-H, 3 p)=-10.36001 \mathrm{eV}-0.55100 \mathrm{eV}=-10.91101 \mathrm{eV} \tag{15.143}
\end{equation*}
$$

And, in Eq. (15.65),

$$
\begin{equation*}
E_{T}\left(\text { atom - atom }, \mathrm{msp}^{3} . A O\right)=0.55100 \mathrm{eV} \tag{15.144}
\end{equation*}
$$

Due to the charge donation from $H$ to $S, c_{1}=1$ in both Eqs. (15.51) and (15.65). As in the case of the $C-H$-bond MO, $C_{1}=0.75$ based on the orbital composition. In alkyl thiols, the energy of sulfur is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{2}$ in Eq. (15.61) is also one, and the energy matching condition is determined by the $C_{2}$ parameter. Using the energy of $S, E(S)=-10.36001 \mathrm{eV}$ in Eq. (15.74), the hybridization factor $C_{2}$ of Eq. (15.61) for the $S-H$-bond MO is:

$$
\begin{equation*}
C_{2}(S 3 p \text { to } H)=\frac{E(S, 3 p)}{E(H)}=\frac{-10.36001 \mathrm{eV}}{-13.60580 \mathrm{eV}}=0.76144 \tag{15.145}
\end{equation*}
$$

Since the energy of $S$ is matched to the Coulombic energy between the electron and proton of $H, E\left(H\left(a_{0}\right)\right)$, $E_{\text {initial }}\left(c_{4} A O / H O\right)=E\left(H\left(a_{0}\right)\right)=-13.60580 \mathrm{eV}, E_{\text {initial }}\left(c_{5} A O / H O\right)=E(H)=-13.59844 \mathrm{eV}$, and $E_{\text {mag }}$ is that corresponding to $E\left(H\left(a_{0}\right)\right)$ given by Eq. (15.67). $E_{D}$ (Group) for hydrogen sulfide is equivalent to that of the $S H$ functional group, and the $E_{D}($ Group $)(\mathrm{eV})$ for dihydrogen sulfide follows the same derivation as that for the $S H$ functional group except that the parameters correspond to $n_{1}=2$ rather than $n_{1}=1$ in Eqs. (15.51) and (15.65).

Furthermore, with the energy of $S$ matched to the Coulombic energy between the electron and proton of $H$, the energy of the $C-S$-bond MO is the sum of the component energies of the $H_{2}$-type ellipsoidal MO given in Eq. (15.51) with $E(A O / H O)=0$ and $E_{T}(A O / H O)=\Delta E_{H_{2} M O}(A O / H O)$. Then, the solution of the $C-S$ functional group comprises the hybridization of the $2 s$ and $2 p$ AOs of $C$ to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $S \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. Since the energy of sulfur is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264), $c_{2}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $C_{2}$ parameter. Then, $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $S$ AO has an energy of $E(S)=-10.36001 \mathrm{eV}$. To meet the equipotential condition of the union of the $C-S H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $C_{2}$ of Eq. (15.60) for the $C-S$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
C_{2}\left(C 2 s p^{3} H O \text { to } \mathrm{S}\right)=\frac{E(S)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(C 2 s p^{3} H O\right)=\frac{-10.36001 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.91771)=0.64965 \tag{15.146}
\end{equation*}
$$

Since the sulfur is energy matched to $E\left(H\left(a_{0}\right)\right)$ in the $S-H$-bond MO, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-S$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $S$ atoms to the MO is -0.72457 eV corresponding to the energy contribution equivalent to that of a methyl group (Eq. (14.151)).

The symbols of the functional groups of branched-chain alkyl thiols are given in Table 15.147. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl thiols are given in Tables 15.148, 15.149, and 15.150, respectively. The total energy of each alkyl thiol given in Table 15.151 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.150 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C 2 s p^{3}$ HO magnetic energy $E_{\text {mag }}$ that is subtracted from the weighted sum of the $E_{D}($ Group $)(\mathrm{eV})$ values based on composition is given by Eq. (15.67). The $C-C$ bonds to the $H C S H$ group (one $H$ bond to $C$ ) were each treated as an iso $C-C$ bond. The $C-C$ bonds to the $C S H$ group (no $H$ bonds to $C$ ) were each treated as a tert-butyl $C-C . E_{m a g}$ was subtracted for each t-butyl group. The bond angle parameters of alkyl thiols determined using Eqs. (15.88-15.117) are given in Table 15.152. The color scale, translucent view of the charge-density of exemplary thiol, ethanethiol, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.25.

Figure 15.25. Color scale, translucent view of the charge-density of ethanethiol showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.147. The symbols of functional groups of alkyl thiols.

| Functional Group | Group Symbol |

## SULFIDES ( $\left.C_{n} H_{2 n+2} S_{m}, n=2,3,4,5 \ldots \infty\right)$

The alkyl sulfides, $C_{n} H_{2 n+2} S_{m}$, comprise two types of $C-S$ functional groups, one for t-butyl groups corresponding to the $C$ and the other for the remaining general alkyl groups including methyl. The alkyl portion of the alkyl sulfide may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in sulfides are equivalent to those in branched-chain alkanes.

Each $C-S$ group is solved by hybridizing the $2 s$ and $2 p$ AOs of the $C$ atom to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the $S \mathrm{AO}$ to form a MO permits each participating orbital to decrease in radius and energy. Since the energy of sulfur is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264), $c_{2}$ in Eq. (15.61) is one, and the energy matching condition is determined by the $C_{2}$ parameter. As in the case of thiols, $C_{2}$ of Eq. (15.61) for the $C-S$-bond MO given by Eq. (15.146) is $C_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to S$)=0.64965$.

The $C-S$ group of alkyl sulfides is equivalent to that of thiols where $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -0.72457 eV (Eq. (14.151)). The t-butyl- $C-S$ group is also equivalent to that of thiols except that the energy parameters corresponding to the oscillation in the transition state are matched to those of the t-butyl group.

The symbols of the functional groups of branched-chain alkyl sulfides are given in Table 15.153. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl sulfides are given in Tables $15.154,15.155$, and 15.156 , respectively. Consider that the $C-S$ bond is along the x axis in the xy plane. The $S$ nucleus is at the focus +c and the $C$ nucleus is at the focus -c. The elliptic angle $\theta^{\prime}$ is taken as counterclockwise from the x-axis for $S$ and as clockwise from the -x-axis for $C$. The total energy of each alkyl sulfide given in Table 15.157 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.156 corresponding to functional-group composition of the molecule. $E_{\text {mag }}$ given by Eq. (15.67) was subtracted for each t-butyl group. The bond angle parameters of alkyl sulfides determined using Eqs. (15.88-15.117) are given in Table 15.158. The color scale, translucent view of the chargedensity of exemplary sulfide, dimethyl sulfide, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.26.

Figure 15.26. Color scale, translucent view of the charge-density of dimethyl sulfide showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## DISULFIDES ( $\left.C_{n} H_{2 n+2} S_{2 m}, \quad n=2,3,4,5 \ldots \infty\right)$

The alkyl disulfides, $C_{n} H_{2 n+2} S_{2 m}$, comprise $C-S$ and $S-S$ functional groups. The alkyl portion of the alkyl disulfide may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne ( CH ) functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in disulfides are equivalent to those in branched-chain alkanes.

Each $C-S$ group is equivalent to that of general alkyl sulfides given in the corresponding section. As in the case of thiols and sulfides, $C_{2}$ of Eq. (15.61) for the $C-S$-bond MO given by Eq. (15.146) is $C_{2}\left(C 2 s p^{3} H O\right.$ to S$)=0.64965$ and $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)$ is -0.72457 eV (Eq. (14.151)).

The $S-S$ group is solved as an $H_{2}$-type-ellipsoidal-MO that is energy matched to the energy of sulfur, $E(S)=-10.36001 \mathrm{eV}$, such that $E(A O / H O)=-10.36001 \mathrm{eV}$ in Eq. (15.51) with $E_{T}(A O / H O)=E(A O / H O)$. The $S-S-$ bond MO is further energy matched to the $C 2 s p^{3} \mathrm{HO}$ of the $C-S$-bond MO. $C_{2}$ of Eq. (15.61) for the $S-S$-bond MO given by Eq. (15.146) is also $C_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to S$)=0.64965$. In order to match $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} \cdot A O\right)$ of the $C-S$ group $\left(-0.72457 \mathrm{eV}\right.$ (Eq. (14.151))), $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $S-S$-bond MO is determined using a linear combination of the AOs corresponding to -0.72457 eV and 0 eV in Eq. (15.29), Eq. (15.31), and Eqs. (15.19-15.20). The result corresponding to bond order 1/2I in Table 15.2 is $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=-0.36229 \mathrm{eV}$.

The symbols of the functional groups of branched-chain alkyl disulfides are given in Table 15.159. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl disulfides are given in Tables $15.160,15.161$, and 15.162 , respectively. The total energy of each alkyl disulfide given in Table 15.163 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.162 corresponding to functionalgroup composition of the molecule. $E_{\operatorname{mag}}$ given by Eq. (15.67) was subtracted for each t-butyl group. The bond angle parameters of alkyl disulfides determined using Eqs. (15.88-15.117) are given in Table 15.164. The color scale, translucent view of the charge-density of exemplary disulfide, dimethyl disulfide, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.27.

Figure 15.27. Color scale, translucent view of the charge-density of dimethyl disulfide showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## SULFOXIDES ( $\left.C_{n} H_{2 n+2}(S O)_{m}, n=2,3,4,5 \ldots \infty\right)$

The alkyl sulfoxides, $C_{n} H_{2 n+2}(S O)_{m}$, comprise a $C-S O-C$ moiety that comprises $C-S$ and $S O$ functional groups. The alkyl portion of the alkyl sulfoxide may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isop.ropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in sulfoxides are equivalent to those in branched-chain alkanes.

The electron configuration of oxygen is $1 s^{2} 2 s^{2} 2 p^{4}$, and the orbital arrangement given by Eq. (10.154) has two unpaired electrons corresponding to the ground state ${ }^{3} P_{2}$. The $S O$ functional group comprises a double bond between the two unpaired electrons of $O$. The sulfur atom is energy matched to the $C 2 s p^{3} \mathrm{HO}$. In alkyl sulfoxides, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $S$ AO has an initial energy of $E(S)=-10.36001 \mathrm{eV}$ [38]. To meet the equipotential condition of the union of the $S=O H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $S=O$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
c_{2}\left(O \text { to } S 3 s p^{3} \text { to } C 2 s p^{3} H O\right)=\frac{E(O)}{E(S)} c_{2}\left(C 2 s p^{3} H O\right)=\frac{-13.61806 \mathrm{eV}}{-10.36001 \mathrm{eV}}(0.91771)=1.20632 \tag{15.147}
\end{equation*}
$$

The $S$ atom also forms a single bond with each of the $C 2 s p^{3}$ HOs of the two $C-S$ groups. The formation of these bonds is permitted by the hybridization of the four electrons of the $S 3 p$ shell to give the orbital arrangement:
$3 \mathrm{sp}^{3}$ state

$$
\begin{equation*}
\frac{\uparrow}{0,0} \quad \frac{\uparrow}{1,-1} \quad \frac{\uparrow}{1,0} \quad \frac{\uparrow}{1,1} \tag{15.148}
\end{equation*}
$$

where the quantum numbers ( $\ell, m_{\ell}$ ) are below each electron. The $3 s$ shell remains unchanged. Then, the Coulombic energy $E_{\text {Coulomb }}\left(S, 3 s p^{3}\right)$ of the outer electron of the $S 3 s p^{3}$ shell given by Eq. (15.137) with $r_{3 s p^{3}}=1.17585 a_{0}$ (Eq. (15.138)) is -11.57099 eV . Using Eq. (15.16) with the radius of the sulfur atom $r_{16}=1.32010 a_{0}$ given by Eq. (10.341), the energy $E\left(S 3 s p^{3}\right)$ of the outer electron of the $S 3 s p^{3}$ shell is given by the sum of $E_{\text {Coulomb }}\left(S 3 s p^{3}\right)$ and $E$ (magnetic):

$$
\begin{align*}
E\left(S 3 s p^{3}\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{3 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r_{16}^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 1.17585 a_{0}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(1.32010 a_{0}\right)^{3}}  \tag{15.149}\\
& =-11.57099 \mathrm{eV}+0.04973=-11.52126 \mathrm{eV}
\end{align*}
$$

Then, the hybridization energy $E_{\text {hybridiation }}\left(S 3 s p^{3}\right)$ of the $S 3 s p^{3}$ HO is

$$
\begin{equation*}
E_{\text {hybridization }}\left(S 3 s p^{3}\right)=E\left(S 3 s p^{3}\right)-E(S)=-11.52126 \mathrm{eV}-10.36001 \mathrm{eV}=-1.16125 \mathrm{eV} \tag{15.150}
\end{equation*}
$$

The $S O$ group is matched to the $C-S$ group with which it shares the common hybridized $S$ atom. Consequently, $E_{\text {hybridization }}\left(S 3 s p^{3}\right)$ is subtracted from $E_{T}($ Group $)$ in the determination of $E_{D}$ (Group) (Eq. (15.65)). Furthermore, the energy of the $S=O$-bond MO is the sum of the component energies of the $H_{2}$-type ellipsoidal MO given in Eq. (15.51) with the energy matched to the final energy of the hybridized $S$ atom such that $E(A O / H O)=E\left(S 3 s p^{3}\right)=-11.52126 \mathrm{eV}$ and $\Delta E_{\mathrm{H}_{2} M O}$ $(A O / H O)=E_{\text {hybridization }}\left(S 3 s p^{3}\right)=-1.16125 \mathrm{eV}$. Then, $E_{T}(A O / H O)=E(S)=-10.36001 \mathrm{eV}$. Also, $E_{T}\left(\right.$ atom - atom,$\left.m s p^{3} . A O\right)$ of the $S=O$ bond is zero since there are no bonds with a $C 2 s p^{3} \mathrm{HO}$

The $C-S$ group is solved as anergy minimum by hybridizing the $2 s$ and $2 p$ AOs of the $C$ atom to form a single $2 s p^{3}$ shell and by hybridizing the four $S 3 p$ electrons to form a $S 3 s p^{3}$ shell, and the sharing of electrons between the $C 2 s p^{3}$ HO and the $S 3 s p^{3} \mathrm{HO}$ to form a MO permits each participating orbital to decrease in radius and energy. Using the Coulombic energy of the $S 3 s p^{3}$ shell, $E_{\text {Coulomb }}\left(S 3 s p^{3}\right)$ given by Eq. (15.139) in Eq. (15.72), the $S 3 s p^{3}$-shell hybridization factor, $c_{2}\left(S 3 s p^{3}\right)$, is:

$$
\begin{equation*}
c_{2}\left(S 3 s p^{3}\right)=\frac{E_{\text {Coulomb }}\left(S 3 s p^{3}\right)}{E(H)}=\frac{-11.57099 \mathrm{eV}}{-13.60580 \mathrm{eV}}=0.85045 \tag{15.151}
\end{equation*}
$$

As in the case of thiols, sulfides, and disulfides, the energy of sulfur is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{1}$ and $c_{2}$ are equal to one in Eq. (15.61), and the energy matching condition is determined by the $C_{2}$ parameter. In alkyl sulfoxides, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)) and the $S 3 s p^{3}$ HO has an energy of $E\left(S 3 s p^{3}\right)=-11.52126 \mathrm{eV}$ (Eq. (15.149)). To meet the equipotential condition of the union of the $C-S H_{2}$-type-ellipsoidalMO with these orbitals, the hybridization factor $C_{2}$ of Eq. (15.61) for the $C-S$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
C_{2}\left(C 2 s p^{3} H O \text { to } S 3 s p^{3}\right)=\frac{E\left(S 3 s p^{3}\right)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(S 3 s p^{3}\right)=\frac{-11.52126 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.85045)=0.66951 \tag{15.152}
\end{equation*}
$$

As in the case of thiols, sulfides, and disulfides, with the energy of $S$ matched to the Coulombic energy between the electron and proton of $H$, the energy of the $C-S$-bond MO is the sum of the component energies of the $H_{2}$-type ellipsoidal MO given in Eq. (15.51) with $E(A O / H O)=0$ and $E_{T}(A O / H O)=\Delta E_{\mathrm{H}_{2} M O}(A O / H O)$. For sulfoxides, $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}(\mathrm{AO} / \mathrm{HO})=-0.72457 \mathrm{eV}$. Further equivalently, $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)=-0.72457 \mathrm{eV}$ (Eq. (14.151)).

The symbols of the functional groups of branched-chain alkyl sulfoxides are given in Table 15.165. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl sulfoxides are given in Tables $15.166,15.167$, and 15.168 , respectively. Consider that the $C-S$ bond is along the x axis in the xy-plane. The $S$ nucleus is at the focus +c and the $C$ nucleus is at the focus -c . The elliptic angle $\theta^{\prime}$ is taken as counterclockwise from the x -axis for $S$ and as clockwise from the -x-axis for $C$. The total energy of each alkyl sulfoxide given in Table 15.169 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.168 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl sulfoxides determined using Eqs. (15.8815.117) are given in Table 15.170. The color scale, translucent view of the charge-density of exemplary sulfoxide, dimethyl sulfoxide, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.28.

Figure 15.28. (A)-(B) Color scale, translucent views of the charge-density of dimethyl sulfoxide showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.169. The total bond energies of alkyl sulfoxides calculated using the functional group composition and the energies of Table 15.168 compared to the experimental values [3].

## DIMETHYL SULFOXIDE DIHEDRAL ANGLE

The dihedral angle $\theta_{\angle S=O / C S C}$ between the plane defined by the $C S C$ MO comprising a linear combination of two $S-C$-bond MOs and a line defined by the $S=O$-bond MO where $S$ is the central atom is calculated using the results given in Table 15.170 and Eqs. (15.114-15.117). The distance $d_{1}$ along the bisector of $\theta_{\angle C S C}$ from $S$ to the internuclear-distance line between $C$ and $C, 2 c^{\prime}{ }_{C-C}$, is given by:

$$
\begin{equation*}
d_{1}=2 c^{\prime}{ }_{S-C} \cos \frac{\theta_{\angle C S C}}{2}=4.9800 a_{0} \cos \frac{96.20^{\circ}}{2}=2.23423 a_{0} \tag{15.153}
\end{equation*}
$$

where $2 c^{\prime}{ }_{S-C}$ is the internuclear distance between $S$ and $C$. The atoms $C, C$, and $O$ define the base of a pyramid. Then, the pyramidal angle $\theta_{\angle C O C}$ can be solved from the internuclear distances between $C$ and $C, 2 c^{\prime}{ }_{C-C}$, and between $C$ and $O$, $2 c^{\prime}{ }_{C-O}$, using the law of cosines (Eq. (15.115)):

Then, the distance $d_{2}$ along the bisector of $\theta_{\angle C O C}$ from $O$ to the internuclear-distance line $2 c^{\prime}{ }_{C-C}$, is given by:

$$
\begin{equation*}
d_{2}=2 c_{C-O}^{\prime} \cos \frac{\theta_{\angle C O C}}{2}=4.95984 a_{0} \cos \frac{60.27^{\circ}}{2}=4.28952 a_{0} \tag{15.155}
\end{equation*}
$$

The lengths $d_{1}, d_{2}$, and $2 c^{\prime}{ }_{S=O}$ define a triangle wherein the angle between $d_{1}$ and the internuclear distance between $O$ and $S$, $2 c_{S=O}^{\prime}$, is the dihedral angle $\theta_{\angle S=O / C S C}$ that can be solved using the law of cosines (Eq. (15.117)).

$$
\begin{equation*}
\theta_{\angle S=O / C S C}=\cos ^{-1}\left(\frac{d_{1}^{2}+\left(2 c_{S=O}^{\prime}\right)^{2}-d_{2}^{2}}{2 d_{1}\left(2 c_{S=O}^{\prime}\right)}\right)=\cos ^{-1}\left(\frac{(2.23423)^{2}+(2.81792)^{2}-(4.28952)^{2}}{2(2.23423)(2.81792)}\right)=115.74^{\circ} \tag{15.156}
\end{equation*}
$$

The experimental [1] dihedral angle $\theta_{\angle S=O / C S C}$ is

$$
\begin{equation*}
\theta_{\angle S=O / C S C}=115.5^{\circ} \tag{15.157}
\end{equation*}
$$

SULFONES ( $\left.C_{n} H_{2 n+2}\left(\mathrm{SO}_{2}\right)_{m}, n=2,3,4,5 \ldots \infty\right)$
The alkyl sulfones, $\mathrm{C}_{n} \mathrm{H}_{2 n+2}\left(\mathrm{SO}_{2}\right)_{m}$, comprise a $\mathrm{C}-\mathrm{SO}_{2}-\mathrm{C}$ moiety that comprises $\mathrm{C}-\mathrm{S}$ and $\mathrm{SO}_{2}$ functional groups. The alkyl portion of the alkyl sulfone may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $\mathrm{C}-\mathrm{C}$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in sulfones are equivalent to those in branched-chain alkanes.

The two unpaired electrons of each $O$ atom form a MO with two unpaired electrons of the sulfur atom such that the MO comprises a linear combination of two bonds, each of bond order two involving the sulfur HOs and oxygen AOs of both oxygen atoms. Due to the bonding between unpaired electrons of different oxygen atoms $E_{\text {mag }}$ (Eq. (15.68)) is subtracted from the total energy. Otherwise, the $\mathrm{SO}_{2}$-bond MO of sulfones is solved in the same manner as the SO -bond MO of sulfoxides given in the corresponding section wherein $n_{1}$ in Eqs. (15.51) and (15.61) is four versus two. Also, the $C-S$-bond MO is equivalent to that of sulfoxides having $E_{T}\left(\right.$ atom -atom, $\left.m s p^{3} . A O\right)=-0.72457 \mathrm{eV}$ (Eq. (14.151)).

The symbols of the functional groups of branched-chain alkyl sulfones are given in Table 15.171. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl sulfones are given in Tables $15.172,15.173$, and 15.174 , respectively. The total energy of each alkyl sulfone given in Table 15.165 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.174 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl sulfones determined using Eqs. (15.88-15.117) are given in Table 15.176. The color scale, translucent view of the charge-density of exemplary sulfone, dimethyl sulfone, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.29.

Figure 15.29. (A)-(B) Color scale, translucent views of the charge-density of dimethyl sulfone showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.176. The bond angle parameters of alkyl sulfones and experimental values [1]. In the calculation of $\theta_{v}$, the parameters from the preceding angle were used. $E_{T}$ is $E_{T}\left(\right.$ atom - atom,$\left.m s p^{3} \cdot A O\right)$.

SULFITES ( $\left.\mathrm{C}_{n} \mathrm{H}_{2 n+2}\left(\mathrm{SO}_{3}\right)_{m}, n=2,3,4,5 \ldots \infty\right)$
The alkyl sulfites, $\mathrm{C}_{n} \mathrm{H}_{2 n+2}\left(\mathrm{SO}_{3}\right)_{m}$, comprise a $\mathrm{C}-\mathrm{O}-\mathrm{SO}-\mathrm{O}-\mathrm{C}$ moiety that comprises two types $\mathrm{C}-\mathrm{O}$ functional groups, one for methyl and one for alkyl, and $O-S$ and $S O$ functional groups. The alkyl portion of the alkyl sulfite may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene ( $\mathrm{CH}_{2}$ ), and methylyne ( CH ) functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in sulfites are equivalent to those in branched-chain alkanes.

The $S O$ functional group is equivalent to that of sulfoxides with $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=0$ as given in the Sulfoxides section. The methyl and alkyl $C-O$ functional groups having $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=-1.44915 \mathrm{eV}$ and $E_{T}\left(\right.$ atom - atom,$\left.m s p^{3} . A O\right)=-1.65376 \mathrm{eV}$, respectively, are equivalent to the corresponding ether groups given in the Ethers section except for the energy terms corresponding to oscillation of the bond in the transition state.

The electron configuration of oxygen is $1 s^{2} 2 s^{2} 2 p^{4}$, and the orbital arrangement given by Eq. (10.154) has two unpaired electrons corresponding to the ground state ${ }^{3} P_{2}$. The $S O$ functional group comprises a double bond between the $S$ atom and the two unpaired electrons of $O$. The $S$ atom also forms single bonds with two additional oxygen atoms that are each further bound to methyl or alkyl groups. The first bond-order bonding in the $O-S$ groups is between the sulfur atom and a $O 2 p$ AO of each oxygen of the two bonds. The formation of these four bonds with the sulfur atom is permitted by the hybridization of the four electrons of the $S 3 p$ shell to give the orbital arrangement given by Eq. (15.148). Then, the Coulombic energy $E_{\text {Coulomb }}\left(S, 3 s p^{3}\right)$ of the outer electron of the $S 3 s p^{3}$ shell given by Eq. (15.139) with $r_{3 s p^{3}}=1.17585 a_{0}$ (Eq. (15.138)) is -11.57099 eV . Using Eq. (15.16) with the radius of the sulfur atom $r_{16}=1.32010 a_{0}$ given by Eq. (10.341), the energy $E\left(S 3 s p^{3}\right)$ of the outer electron of the $S 3 s p^{3}$ shell given by the sum of $E_{\text {Coulomb }}\left(S 3 s p^{3}\right)$ and $E$ (magnetic) is $E\left(S 3 s p^{3}\right)=-11.52126 \mathrm{eV}($ Eq. (15.149)).

Thus, the $O-S$ group is solved as an energy minimum by hybridizing the four $S 3 p$ electrons to form a $S 3 s p^{3}$ shell, and the sharing of electrons between the $O 2 p \mathrm{AO}$ and the $S 3 s p^{3} \mathrm{HO}$ to form a MO permits each participating orbital to decrease in radius and energy. As in the case of thiols, sulfides, disulfides, and sulfoxides, the energy of sulfur is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{1}$ and $c_{2}$ are equal to one in Eq. (15.61), and the energy matching condition is determined by the $C_{2}$ parameter. Each $C 2 s p^{3}$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), and the $S$ HO has an energy of $E\left(S 3 s p^{3}\right)=-11.52126 \mathrm{eV}$. To meet the equipotential condition of the union of the $O-S H_{2}$-type-ellipsoidal-MO with these orbitals with the oxygen that further bonds to a $C 2 s p^{3} \mathrm{HO}$, the hybridization factor $C_{2}$ of Eq. (15.61) for the $O-S$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
C_{2}\left(S 3 s p^{3} \text { to } O \text { to } C 2 s p^{3} H O\right)=\frac{E\left(S, 3 s p^{3}\right)}{E(O, 2 p)} c_{2}\left(C 2 s p^{3} H O\right)=\frac{-11.52126 \mathrm{eV}}{-13.61806 \mathrm{eV}}(0.91771)=0.77641 \tag{15.158}
\end{equation*}
$$

As in the case of thiols, sulfides, disulfides, and sulfoxides, with the energy of $S$ matched to the Coulombic energy between the electron and proton of $H$, the energy of the $O-S$-bond MO is the sum of the component energies of the $H_{2}$-type ellipsoidal MO given in Eq. (15.51) with $E(A O / H O)=0$ and $E_{T}(A O / H O)=\Delta E_{H_{2} M O}(A O / H O)$. For sulfites, $\Delta E_{H_{2} M O}(A O / H O)=-0.92918 \mathrm{eV}$ and equivalently, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=-0.92918 \mathrm{eV}$ (Eq. (14.513)) due to the maximum energy match with the oxygen AO as in the case with carboxylic acid esters.
The symbols of the functional groups of branched-chain alkyl sulfites are given in Table 15.177. The geometrical (Eqs. (15.115.5 ) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl sulfites are given in Tables 15.178, 15.179, and 15.180, respectively. The total energy of each alkyl sulfite given in Table 15.175 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.180 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl sulfites determined using Eqs. (15.88-15.117) are given in Table 15.182. The color scale, translucent view of the charge-density of sulfite, dimethyl sulfite, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.30.

Figure 15.30. Color scale, translucent view of the charge-density of dimethyl sulfite showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

SULFATES $\left(C_{n} H_{2 n+2}\left(S O_{4}\right)_{m}, n=2,3,4,5 \ldots \infty\right)$
The alkyl sulfates, $\mathrm{C}_{n} \mathrm{H}_{2 n+2}\left(\mathrm{SO}_{4}\right)_{m}$, comprise a $\mathrm{C}-\mathrm{O}-\mathrm{SO}_{2}-\mathrm{O}-\mathrm{C}$ moiety that comprises two types $\mathrm{C}-\mathrm{O}$ functional groups, one for methyl and one for alkyl, and $\mathrm{O}-\mathrm{S}$ and $\mathrm{SO}_{2}$ functional groups. The alkyl portion of the alkyl sulfate may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne ( CH ) functional groups as well as $C$ bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n -alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in sulfates are equivalent to those in branched-chain alkanes.

The methyl and alkyl $C-O$ functional groups having $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=-1.44915 \mathrm{eV}$ and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=-1.65376 \mathrm{eV}$, respectively, are equivalent to the corresponding groups given in the Sulfites section. The $O-S$ functional group having $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=-0.92918 \mathrm{eV}$ is equivalent to that given in the Sulfites section. The $\mathrm{SO}_{2}$ functional group is equivalent to that of sulfones with $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=0$ as given in the Sulfones section.

The symbols of the functional groups of branched-chain alkyl sulfates are given in Table 15.183. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl sulfates are given in Tables 15.184, 15.185, and 15.186, respectively. The total energy of each alkyl sulfate given in Table 15.187 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.186 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl sulfates determined using Eqs. ( $15.88-15.117$ ) are given in Table 15.188 . The color scale, translucent view of the charge-density of exemplary sulfate, dimethyl sulfate, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.31.

Figure 15.31. (A)-(B) Color scale, translucent views of the charge-density of dimethyl sulfate showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.183. The symbols of functional groups of alkyl sulfates.

| Functional Group | Group Symbol |
| :---: | :---: |

## NITROALKANES $\left(C_{n} H_{2 n+2-m}\left(N O_{2}\right)_{m}, n=1,2,3,4,5 \ldots \infty\right)$

The nitroalkanes, $C_{n} H_{2 n+2-m}\left(\mathrm{NO}_{2}\right)_{m}$, comprise a $\mathrm{NO}_{2}$ functional group and a $\mathrm{C}-\mathrm{N}$ functional group. The alkyl portion of the nitroalkane may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne ( CH ) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $\mathrm{C}-\mathrm{C}$ bond is the same as that of straight-chain alkanes. In addition, the $\mathrm{C}-\mathrm{C}$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and tbutyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $\mathrm{C}-\mathrm{C}$ bonds comprise functional groups. The branched-chain-alkane groups in nitroalkanes are equivalent to those in branched-chain alkanes.

The electron configuration of oxygen is $1 s^{2} 2 s^{2} 2 p^{4}$, and the orbital arrangement given by Eq. (10.154) has two unpaired electrons corresponding to the ground state ${ }^{3} P_{2}$. The electron configuration of nitrogen is $1 s^{2} 2 s^{2} 2 p^{3}$, and the orbital arrangement given by Eq. (10.134) has three unpaired electrons corresponding to the ground state ${ }^{4} S_{3 / 2}^{0}$. The bonding in the nitro $\left(\mathrm{NO}_{2}\right)$ functional group is similar to that in the $\mathrm{SO}_{2}$ group given previously. It also has similarities to the bonding in the carbonyl functional group. In the $\mathrm{NO}_{2}$ group, the two unpaired electrons of the $O$ atoms form a MO with two unpaired electrons of the nitrogen atom such that the MO comprises a linear combination of two bonds, each of bond order two involving the nitrogen AOs and oxygen AOs of both oxygen atoms. The nitrogen atom is then energy matched to the $C 2 s p^{3} \mathrm{HO}$. In nitroalkanes, the $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)), the $N$ AO has an energy of $E(N)=-14.53414 \mathrm{eV}$, and the $O$ AO has an energy of $E(O)=-13.61806 \mathrm{eV}$ [38]. To meet the equipotential condition of the union of the $N=O H_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $N=O$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
c_{2}\left(O \text { to } N 2 p \text { to } C 2 s p^{3} H O\right)=\frac{E(O)}{E(N)} c_{2}\left(C 2 s p^{3} H O\right)=\frac{-13.61806 \mathrm{eV}}{-14.53414 \mathrm{eV}}(0.91771)=0.85987 \tag{15.159}
\end{equation*}
$$

Since there are two $O$ atoms in a linear combination that comprises the bonding of the $\mathrm{NO}_{2}$ group, the unpaired electrons of each $O$ cancel each others effect such that $E_{\text {mag }}$ is not subtracted from the total energy of $N O_{2}$. Additionally, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=-3.71673 \mathrm{eV}=4(-0.92918 \mathrm{eV})$ (Eq. (14.513)) is the maximum given the bonding involves four electrons comprising two bonds, each having a bond order of one.

The $C-N$ group is equivalent to that of primary amines except that the energies corresponding to vibration in the transition state are matched to a nitroalkane and $\Delta E_{H_{2} M O}(A O / H O)=-0.72457 \mathrm{eV}$ for nitroalkane and $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}(\mathrm{AO} / \mathrm{HO})=-1.44915 \mathrm{eV}$ for primary amines. Whereas, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . \mathrm{AO}\right)=-1.44915 \mathrm{eV}$ for both functional groups. This condition matches the energy of the $\mathrm{C}-\mathrm{N}$ group with the $\mathrm{NO}_{2}$ having $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}(\mathrm{AO} / \mathrm{HO})=0$.

The symbols of the functional groups of branched-chain nitroalkanes are given in Table 15.189. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of nitroalkanes are given in Tables $15.190,15.191$, and 15.192 , respectively. The total energy of each nitroalkane given in Table 15.193 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.192 corresponding to functional-group composition of the molecule. $E_{\text {mag }}$ given by Eq. (15.67) was subtracted for each t-butyl group. The bond angle parameters of nitroalkanes determined using Eqs. (15.88-15.117) are given in Table 15.194. The color scale, translucent view of the chargedensity of exemplary nitroalkane, nitroethane, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.32.

Figure 15.32. Color scale, translucent view of the charge-density of nitroethane showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## ALKYL NITRITES ( $\left.C_{n} H_{2 n+2-m}\left(\mathrm{NO}_{2}\right)_{m}, n=1,2,3,4,5 \ldots \infty\right)$

The alkyl nitrites, $C_{n} H_{2 n+2-m}\left(\mathrm{NO}_{2}\right)_{m}$, comprise a $\mathrm{RC}-\mathrm{O}-\mathrm{NO}$ moiety that comprises $\mathrm{C}-\mathrm{O}, \mathrm{O}-\mathrm{N}$, and NO functional groups. The alkyl portion of the alkyl nitrite may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl nitrites are equivalent to those in branched-chain alkanes.

The electron configuration of oxygen is $1 s^{2} 2 s^{2} 2 p^{4}$, and the orbital arrangement given by Eq. (10.154) has two unpaired electrons corresponding to the ground state ${ }^{3} P_{2}$. The electron configuration of nitrogen is $1 s^{2} 2 s^{2} 2 p^{3}$, and the orbital arrangement given by Eq. (10.134) has three unpaired electrons corresponding to the ground state ${ }^{4} S_{3 / 2}^{0}$. The bonding in the nitro ( $N O$ ) functional group is similar to that in the $S O$ group given previously. It also has similarities to the bonding in the carbonyl functional group. In the $N O$ group, the two unpaired electrons of the $O$ atom form a MO with two unpaired electrons of the nitrogen atom such that the MO comprises a double bond. The nitrogen atom is then energy matched to the $O-N$ functional group that is further energy matched to the $C 2 s p^{3} \mathrm{HO}$ of the $C-O$ functional group. To meet the equipotential condition of the union of the $\mathrm{N}=\mathrm{O} \mathrm{H}_{2}$-type-ellipsoidal-MO with other orbitals of the molecule, the hybridization factor $c_{2}$ of Eq. (15.60) for the $N=O$-bond MO given by Eq. (15.159) is $c_{2}\left(O\right.$ to $N 2 p$ to $\left.C 2 s p^{3} H O\right)=0.85987$.

As in the case of the carbonyl group, two unpaired $O$ electrons result upon bond breakage of the $N=O$ bond which requires that two times $E_{m a g}$ of oxygen (Eq. (15.68)) be subtracted from the total energy of $N O$. Additionally, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ and $\Delta E_{H_{2} M O}(A O / H O)$ are equal to -0.92918 eV (Eq. (14.513)) which matches the energy of the $N=O$ bond with the contiguous $O-N$ bond and matches the energy contribution of an oxygen atom.

The $O-N$ functional group comprise a single-bond, $H_{2}$-type-ellipsoidal-MO between the remaining unpaired nitrogen electron and an unpaired electron of the second oxygen atom which further forms a single bond with the $C 2 s p^{3} \mathrm{HO}$ of the $C-O$ functional group. In alkyl nitrites, the hybridization factor $c_{2}$ of Eq. (15.61) for the $C-O$-bond MO given by Eq. (15.133) is $c_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to $\left.O\right)=0.85395$. The hybridization factor $c_{2}$ of Eq. (15.61) for a $C-N$-bond MO given by Eq. (15.135) is $c_{2}\left(C 2 s p^{3} \mathrm{HO}\right.$ to $\left.N\right)=0.91140$. Thus, the hybridization factor $c_{2}$ of Eq. (15.61) for $O-N$ that bridges the $C-O$ and $N=O$ bonds given by Eq. (15.78) is:

$$
\begin{equation*}
c_{2}(N 2 p \text { to } O 2 p)=\frac{c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } \mathrm{N}\right)}{c_{2}\left(C 2 s p^{3} \mathrm{HO} \text { to } O\right)}=\frac{0.91140}{0.85395}=1.06727 \tag{15.160}
\end{equation*}
$$

$E_{T}\left(\right.$ atom-atom,$\left.m s p^{3} . A O\right)=-0.92918 \mathrm{eV}$ in order to match the energy of the NO group and $E(A O / H O)=-15.35946 \mathrm{eV}$ in order to match the $C-O$ functional group.

The $C-O$ functional group is equivalent to that of an ether as given in the corresponding section except that $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)$ and $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}(\mathrm{AO} / \mathrm{HO})$ are both -0.72457 eV which matches the energy contribution of an independent $C 2 s p^{3} \mathrm{HO}$ (Eq. (14.151)). Also, the energy terms corresponding to the oscillation of the bond in the transition state are matched to a nitrite.

The symbols of the functional groups of branched-chain alkyl nitrites are given in Table 15.195. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl nitrites are given in Tables $15.196,15.197$, and 15.198 , respectively. The total energy of each alkyl nitrite given in Table 15.199 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.198 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl nitrites determined using Eqs. (15.88-15.117) are given in Table 15.200 . The color scale, translucent view of the charge-density of exemplary alkyl nitrite, methyl nitrite, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.33.

Figure 15.33. (A)-(B) Color scale, translucent views of the charge-density of methyl nitrite showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

ALKYL NITRATES ( $\left.\mathrm{C}_{n} \mathrm{H}_{2 n+2-m}\left(\mathrm{NO}_{3}\right)_{m}, \quad n=1,2,3,4,5 \ldots \infty\right)$
The alkyl nitrates, $\mathrm{C}_{n} \mathrm{H}_{2 n+2-m}\left(\mathrm{NO}_{3}\right)_{m}$, comprise a $\mathrm{RC}-\mathrm{O}-\mathrm{NO}_{2}$ moiety that comprises $\mathrm{C}-\mathrm{O}, \mathrm{O}-\mathrm{N}$, and $\mathrm{NO}_{2}$ functional groups. The alkyl portion of the alkyl nitrate may comprise at least two terminal methyl groups $\left(\mathrm{CH}_{3}\right)$ at each end of the chain, and may comprise methylene $\left(\mathrm{CH}_{2}\right)$, and methylyne $(\mathrm{CH})$ functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)$ and t-butyl $\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}\right)$ groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl nitrates are equivalent to those in branched-chain alkanes.

The $\mathrm{NO}_{2}$ functional group is equivalent to that of nitro alkanes with the exception that $\Delta E_{\mathrm{H}_{2} \mathrm{NO}}(\mathrm{AO} / \mathrm{HO})$ as well as $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is equal to -3.71673 eV in order to match the group energy to that of the contiguous $O-N$ bond. Furthermore, the $O-N$ group with $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=-0.92918 \mathrm{eV}$ is equivalent to that of nitrites as given in the corresponding section.

The $C-O$ functional group is equivalent to that of an ether as given in the corresponding section except that $E_{T}\left(\right.$ atom-atom,$\left.m s p^{3} . A O\right)$ and $\Delta E_{H_{2} M O}(A O / H O)$ are both -0.92918 eV which matches the energy contribution of an independent $C 2 s p^{3} \mathrm{HO}$ (Eq. (14.513)). Also, the energy terms corresponding to the oscillation of the bond in the transition state are matched to a nitrate.

The symbols of the functional groups of branched-chain alkyl nitrates are given in Table 15.201. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl nitrates are given in Tables 15.202, 15.203, and 15.204, respectively. The total energy of each alkyl nitrate given in Table 15.205 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.204 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl nitrates determined using Eqs. (15.88-15.117) are given in Table 15.206. The color scale, translucent view of the charge-density of exemplary alkyl nitrate, ethyl nitrate, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.34.

Figure 15.34. (A)-(B) Color scale, translucent views of the charge-density of ethyl nitrate showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## CYCLIC AND CONJUGATED ALKENES ( $C_{n} H_{2 n+2-2 m-2 c}, n=3,4,5 \ldots \infty, m=1,2,3 \ldots, c=0$ or 1 )

The cyclic and conjugated alkenes are represented by the general formula $C_{n} H_{2 n+2-2 m-2 c}, n=3,4,5 \ldots \infty, m=1,2,3 \ldots, c=0$ or 1 where $m$ is the number of double bonds and $c=0$ for a straight-chain alkene and $c=1$ for a cyclic alkene. They have at least one carbon-carbon double bond comprising a functional group that is solved equivalently to the double bond of ethylene. Consider the cyclic and conjugated alkenes 1,3-butadiene, 1,3-pentadiene, 1,4-pentadiene, 1,3-cyclopentadiene, and cyclopentene. Based on the condition of energy matching of the orbital, any magnetic energy due to unpaired electrons in the constituent fragments, and differences in oscillation in the transition state, five distinct $C-C$ functional groups can be identified as given in Table 15.208. The designation of the structure of the groups are shown in Figures 15.35A-E. In addition, $\mathrm{CH}_{2}$ of any $-\mathrm{C}=\mathrm{CH}_{2}$ moiety is a conjugated alkene functional group. The alkyl portion of the cyclic or conjugated alkene may comprise at least one terminal methyl group $\left(\mathrm{CH}_{3}\right)$, and may comprise methylene ( $\mathrm{CH}_{2}$ ), and methylyne ( CH ) functional groups that are equivalent to those of branched-chain alkanes.

The solution of the functional groups comprises the hybridization of the $2 s$ and $2 p$ AOs of each $C$ to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ HOs to form a MO permits each participating hybridized orbital to decrease in radius and energy. The $C-C$ groups are solved in the same manner as those of the branched-chain alkanes given in the corresponding section. For example, the cyclopentene $C_{a}-C_{b}$ group is equivalent to the $\mathrm{n}-C-C$ alkane group. Many of the corresponding energies of the molecules of this class are similar, and they can be related to one another based on the structure. For example, cyclopentadiene is formed by ring closure of 1,3-pentadiene with the elimination of $H$ from the terminal methyl and methylene groups. Thus, the energy of each of the corresponding carbon-carbon bonds in cyclopentadiene is the same as that in 1,3-pentadiene except that the difference between the energies of the 1,3pentadiene $C_{c}-C_{d}$ and the cyclopentadiene $C_{a}-C_{b}$ groups is the magnetic energy (Eq. (15.67)) which is subtracted from the $C_{a}-C_{b}$ total bond energy according to Eqs. (13.524-13.527) due to the formation of a CH group from the methylene group. The color scale, translucent view of the charge-density of exemplary cyclic and conjugated alkene, 1,3-butadiene, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.35.

Figure 15.35. Color scale, translucent view of the charge-density of 1,3 -butadiene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C=C$-bond MO in Eq. (15.61) due to the charge donation from the $C$ atoms to the MO is equivalent to that of ethylene, -2.26759 eV , given by Eq. (14.247). $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ of each $C-C$-bond MO in Eq. (15.61) is -2.26759 eV or -1.85836 eV based on the energy match between the $C 2 s p^{3} \mathrm{HOs}$ corresponding to the energy contributions equivalent to those of alkene, -1.13379 eV (Eq. (14.247)), or methylene, -0.92918 eV (Eq. (14.513)), groups, respectively, that are contiguous with the $C-C$-bond carbons. In the former case, the total energy of the $C-C$ bond MO is matched to that of the alkane energy in the determination of the bond length. The charge density of 0.5 e must be donated to the $C-C$ bond in order to match the energy of the adjacent flanking double bonds. This further lowers the total energy of the $C-C$-bond MO and increases the $C-C$ bond energy. This additional lowering of the $C-C$-bond energy by additional charge donation over that of an alkane bond due to adjacent double bonds is called conjugation.

The symbols of the functional groups of cyclic and conjugated alkenes are given in Table 15.207. The structures of 1,3butadiene, 1,3-pentadiene, 1,4-pentadiene, 1,3-cyclopentadiene, and cyclopentene are shown in Figures 15.35A-E, respectively. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of cyclic and conjugated alkenes are given in Tables $15.208,15.209$, and 15.210 , respectively. The total energy of each cyclic or conjugated alkenes given in Table 15.211 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of

Table 15.210 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C 2 s p^{3} \mathrm{HO}$ magnetic energy $E_{\text {mag }}$ that is subtracted from the weighted sum of the $E_{D}($ Group $)(e V)$ values based on composition is given by Eq. (15.67). The bond angle parameters of cyclic and conjugated alkenes determined using Eqs. (15.88-15.117) are given in Table 15.212.

## AROMATIC AND HETEROCYCLIC COMPOUNDS

Aromatic and heterocyclic molecules comprise at least one of an aromatic or a cyclic conjugated alkene functional group. The latter was described in the Cyclic and Conjugated Alkenes section. The aromatic bond is uniquely stable and requires the sharing of the electrons of multiple $H_{2}$-type MOs. The results of the derivation of the parameters of the benzene molecule given in the Benzene Molecule $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ section can be generalized to any aromatic functional group(s) of aromatic and heterocyclic compounds.
$\mathrm{C}_{6} \mathrm{H}_{6}$ can be considered a linear combination of three ethylene molecules wherein a $\mathrm{C}-\mathrm{H}$ bond of each $\mathrm{CH}_{2}$ group of $\mathrm{H}_{2} \mathrm{C}=\mathrm{CH}_{2}$ is replaced by a $\mathrm{C}=\mathrm{C}$ bond to form a six-member ring of carbon atoms. The solution of the ethylene molecule is given in the Ethylene Molecule $\left(\mathrm{CH}_{2} \mathrm{CH}_{2}\right)$ section. The radius $r_{\text {ethylene } 2 s p^{3}}\left(0.85252 a_{0}\right)$ of the $C 2 s p^{3}$ shell of ethylene calculated from the Coulombic energy is given by Eq. (14.244). The Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {ethylene }}, 2 s p^{3}\right)(-15.95955 \mathrm{eV})$ of the outer electron of the $C 2 s p^{3}$ shell is given by Eq. (14.245). The energy $E\left(C_{\text {ethylene }}, 2 s p^{3}\right)(-15.76868 \mathrm{eV})$ of the outer electron of the $C 2 s p^{3}$ shell is given by Eq. (14.246). $E_{T}\left(C=C, 2 s p^{3}\right)(-1.13380 \mathrm{eV})$ (Eq. (14.247)), the energy change of each $C 2 s p^{3}$ shell with the formation of the $C=C$-bond MO is given by the difference between $E\left(C_{\text {ethylene }}, 2 s p^{3}\right)$ and $E\left(C, 2 s p^{3}\right) . C_{6} H_{6}$ can be solved using the same principles as those used to solve ethylene wherein the $2 s$ and $2 p$ shells of each $C$ hybridize to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. Each $2 s p^{3} \mathrm{HO}$ of each carbon atom initially has four unpaired electrons. Thus, the $6 H$ atomic orbitals (AOs) of benzene contribute six electrons and the six $s p^{3}$-hybridized carbon atoms contribute twenty-four electrons to form six $C-H$ bonds and six $C=C$ bonds. Each $C-H$ bond has two paired electrons with one donated from the $H \mathrm{AO}$ and the other from the $C 2 s p^{3} \mathrm{HO}$. Each $C=C$ bond comprises a linear combination of a factor of 0.75 of four paired electrons (three electrons) from two sets of two $C 2 s p^{3} \mathrm{HOs}$ of the participating carbon atoms. Each $C-H$ and each $C=C$ bond comprises a linear combination of one and two diatomic $H_{2}$ type MOs developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section, respectively. Consider the case where three sets of $C=C$-bond MOs form bonds between the two carbon atoms of each molecule to form a six-member ring such that the six resulting bonds comprise eighteen paired electrons. Each bond comprises a linear combination of two MOs wherein each comprises two $C 2 s p^{3} \mathrm{HOs}$ and $75 \%$ of a $H_{2}$-type ellipsoidal MO divided between the $C 2 s p^{3}$ HOs:

$$
\begin{equation*}
\binom{3\left(2{\mathrm{C} 2 s p^{3}}^{3}+0.75 \mathrm{H}_{2} \mathrm{MO}\right) \rightarrow 3\left(C_{=}^{4 e} \mathrm{C}\right) \text {-ethylene-type-bond MO}}{\rightarrow 6\left(C^{3 e}=C\right) \text {-bond MO of benzene }} \tag{15.161}
\end{equation*}
$$

The linear combination of each $H_{2}$-type ellipsoidal MO with each $C 2 s p^{3}$ HO further comprises an excess of $25 \%$ chargedensity contribution per bond from each $C 2 s p^{3} \mathrm{HO}$ to the $C=C$-bond MO to achieve an energy minimum. Thus, the dimensional parameters of each bond $C=C$-bond are determined using Eqs. (15.51) and (15.1-15.5) in a form that are the same equations as those used to determine the same parameters of the $C=C$-bond MO of ethylene (Eqs. (14.242-14.268)) while matching the boundary conditions of the structure of benzene.

Hybridization with $25 \%$ electron donation to each $C=C$-bond gives rise to the $C_{\text {benzene }} 2 s p^{3}$ HO-shell Coulombic energy $E_{\text {Coulomb }}\left(C_{\text {benzene }}, 2 s p^{3}\right)$ given by Eq. (14.245). To meet the equipotential condition of the union of the six $C 2 s p^{3} \mathrm{HOs}, c_{2}$ and $C_{2}$ of Eq. (15.51) for the aromatic $C \stackrel{3 e}{=} C$-bond MO is given by Eq. (15.71) as the ratio of 15.95955 eV , the magnitude of $E_{\text {Coulomb }}\left(C_{\text {benzene }}, 2 s p^{3}\right)$ (Eq. (14.245)), and 13.605804 eV , the magnitude of the Coulombic energy between the electron and proton of $H$ (Eq. (1.264)):

$$
\begin{equation*}
C_{2}\left(\text { benzene } C 2 s p^{3} \mathrm{HO}\right)=c_{2}\left(\text { benzene } C 2 s p^{3} \mathrm{HO}\right)=\frac{13.605804 \mathrm{eV}}{15.95955 \mathrm{eV}}=0.85252 \tag{15.162}
\end{equation*}
$$

The energies of each $C \stackrel{3 e}{=} C$ bond of benzene are also determined using the same equations as those of ethylene (Eqs. (14.251-14.253) and (14.319-14.333)) with the parameters of benzene. Ethylene serves as a basis element for the $C=C$ bonding of benzene wherein each of the six $C=C$ bonds of benzene comprises $(0.75)(4)=3$ electrons according to Eq. (15.161). The total energy of the bonds of the eighteen electrons of the $C=\frac{3 e}{=} C$ bonds of benzene, $E_{T}\left(C_{6} H_{6}, C=C\right)$, is given by (6)(0.75) times $E_{T+o s c}(C=C)(E q .(14.492))$, the total energy of the $C \stackrel{3 e}{=} C$-bond MO of benzene including the Doppler term, minus eighteen times $E\left(C, 2 s p^{3}\right)$ (Eq. (14.146)), the initial energy of each $C 2 s p^{3} \mathrm{HO}$ of each $C$ that forms the $C^{3 e}=C$ bonds of bond order two.

Thus, the total energy of the six $C \stackrel{3 e}{=} C$ bonds of benzene with three electron per aromatic bond given by Eq. (14.493) is:

$$
\begin{align*}
E_{T}\left(C_{6} H_{6}, C \stackrel{3 e}{=} C\right) & =(6)(0.75) E_{T+\text { osc }}(C=C)-(6)(3) E\left(C, 2 s p^{3}\right) \\
& =(6)(0.75)(-66.05796 \mathrm{eV})-18(-14.63489 \mathrm{eV})  \tag{15.163}\\
& =-297.26081 \mathrm{eV}-(-263.42798 \mathrm{eV})=-33.83284 \mathrm{eV}
\end{align*}
$$

The results of benzene can be generalized to the class of aromatic and heterocyclic compounds. $E_{h v}$ of an aromatic bond is given by $E_{T}\left(H_{2}\right)$ (Eqs. (11.212) and (14.486)), the maximum total energy of each $H_{2}$-type MO such that:

$$
\begin{equation*}
\bar{E}_{\text {osc }}=n_{1}\left(\bar{E}_{D}+\bar{E}_{\text {Kvib }}\right)=n_{1}\left(-31.63536831 \mathrm{eV} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right) \tag{15.164}
\end{equation*}
$$

The factor of 0.75 corresponding to the three electrons per aromatic bond of bond order two given in the Benzene Molecule $\left(C_{6} H_{6}\right)$ section modifies Eqs. (15.61-15.65). Multiplication of the total energy given by Eq. (15.64) by $f_{1}=0.75$ with the substitution of Eq. (15.164) gives the total energy of the aromatic bond:

The total bond energy of the aromatic group $E_{D}($ Group $)$ is the negative difference of the total energy of the group (Eq. (15.165)) and the total energy of the starting species given by the sum of $c_{4} E_{\text {initial }}\left(c_{4} \mathrm{AO} / \mathrm{HO}\right)$ and $c_{5} E_{\text {initial }}\left(c_{5} \mathrm{AO} / \mathrm{HO}\right)$ :

$$
E_{D}(\text { Group })=-\binom{\binom{E(\text { basis energies })+E_{T}\left(\text { atom }- \text { atom }, m s p^{3} . A O\right)}{f_{1}\left(\begin{array}{l}
2 \hbar \sqrt{\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{0} R^{3}}}  \tag{15.166}\\
-31.63536831 \mathrm{eV} \\
\frac{m_{e}}{m_{e} c^{2}}
\end{array}+n_{1} \bar{E}_{K v i b}+c_{3} \frac{8 \pi \mu_{0} \mu_{B}^{2}}{r^{3}}\right.}}{-\left(c_{4} E_{\text {initial }}(A O / H O)+c_{5} E_{\text {initial }}\left(c_{5} A O / H O\right)\right)}
$$

Since there are three electrons per aromatic bond, $c_{4}$ is three times the number of aromatic bonds.
Benzene can also be considered as comprising chemical bonds between six CH radicals wherein each radical comprises a chemical bond between carbon and hydrogen atoms. The solution of the parameters of CH is given in the Hydrogen Carbide $(\mathrm{CH})$ section. Those of the benzene are given in the Benzene Molecule $\left(\mathrm{C}_{6} H_{6}\right)$ section. The energy components of $V_{e}, V_{p}, T$, $V_{m}$, and $E_{T}$ are the same as those of the hydrogen carbide radical, except that $E_{T}\left(C=C, 2 s p^{3}\right)=-1.13379 \mathrm{eV}$ (Eq. (14.247)) is subtracted from $E_{T}(C H)$ of Eq. (13.495) to match the energy of each $C-H$-bond MO to the decrease in the energy of the corresponding $C 2 s p^{3} \mathrm{HO}$. In the corresponding generalization of the aromatic CH group, the geometrical parameters are determined using Eq. (15.51) and Eqs. (15.1-15.5) with $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=-1.13379 \mathrm{eV}$.

The total energy of the benzene $C-H$-bond MO, $E_{T_{\text {beresere }}}(C-H)$, given by Eq. (14.467) is the sum of $0.5 E_{T}\left(C=C, 2 s p^{3}\right)$, the energy change of each $C 2 s p^{3}$ shell per single bond due to the decrease in radius with the formation of the corresponding $C=\stackrel{3 e}{=} C$-bond MO (Eq. (14.247)), and $E_{T_{\text {berecene }}}(C H)$, the $\sigma$ MO contribution given by Eq. (14.441). In the corresponding generalization of the aromatic $C H$ group, the energy parameters are determined using Eqs. (15.165-15.166) with $f_{1}=1$ and $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)=\frac{-1.13379 \mathrm{eV}}{2}$. Thus, the energy contribution to the single aromatic CH bond is one half that of the $C \stackrel{3 e}{=} C$ double bond contribution. This matches the energies of the $C H$ and $C=C$ aromatic groups, conserves the electron number with the equivalent charge density as that of $s=1$ in Eqs. (15.18-15.21), and further gives a minimum energy for the molecule. Breakage of the aromatic $C \stackrel{3 e}{=} C$ bonds to give $C H$ groups creates unpaired electrons in these fragments that corresponds to $c_{3}=1$ in Eq. (15.65) with $E_{\text {mag }}$ given by Eq. (15.67).

Each of the $C-H$ bonds of benzene comprises two electrons according to Eq. (14.439). From the energy of each $C-H$ bond, $-E_{D_{\text {benzene }}}\left({ }^{12} \mathrm{CH}\right)$ (Eq. (14.477)), the total energy of the twelve electrons of the six $C-H$ bonds of benzene, $E_{T}\left(C_{6} H_{6}, C-H\right)$, given by Eq. (14.494) is:

$$
\begin{equation*}
E_{T}\left(C_{6} H_{6}, C-H\right)=(6)\left(-E_{D_{\text {benzene }}}\left({ }^{12} \mathrm{CH}\right)\right)=6(-3.90454 \mathrm{eV})=-23.42724 \mathrm{eV} \tag{15.167}
\end{equation*}
$$

The total bond dissociation energy of benzene, $E_{D}\left(C_{6} H_{6}\right)$, given by Eq. (14.495) is the negative sum of $E_{T}\left(C_{6} H_{6}, C \stackrel{3 e}{=} C\right)$ (Eq. (14.493)) and $E_{T}\left(C_{6} H_{6}, C-H\right)$ (Eq. (14.494)):

$$
\begin{equation*}
E_{D}\left(C_{6} H_{6}\right)=-\left(E_{T}\left(C_{6} H_{6}, C \stackrel{3 e}{=} C\right)+E_{T}\left(C_{6} H_{6}, C-H\right)\right)=-((-33.83284 \mathrm{eV})+(-23.42724 \mathrm{eV}))=57.2601 \mathrm{eV} \tag{15.168}
\end{equation*}
$$

Using the parameters given in Tables 15.214 and 15.216 in the general equations (Eqs. (15.51), (15.1-15.5), and (15.165-15.166)) reproduces the results for benzene given in the Benzene Molecule $\left(C_{6} H_{6}\right)$ section as shown in Tables 15.214 and 15.216.

The symbols of the functional groups of aromatics and heterocyclics are given in Table 15.213. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of aromatics and heterocyclics are given in Tables $15.214,15.215$, and 15.216 , respectively. The total energy of benzene given in Table 15.217 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.216 corresponding to functional-group composition of the molecule. The bond angle parameters of benzene determined using Eqs. (15.88-15.117) are given in Table 15.218. The color scale, translucent view of the charge-density of exemplary aromatic, benzene, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.36.

Figure 15.36. Color scale, translucent view of the charge-density of benzene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.217. The total bond energies of benzene calculated using the functional group composition and the energies of Table 15.216 compared to the experimental values [3]

## NAPHTHALENE

Naphthalene has the formula $C_{10} H_{8}$ and comprises a planar molecule with two aromatic rings that share a common $C-C$ group. In order to be aromatic, the total number of bonding electrons must be a multiple of 3 since the number of electrons of the aromatic bond is $(0.75)(4)=3$ as shown in the Benzene section. In the case of naphthalene, the peripheral 10 carbons form the aromatic MO with the center bridged by a $C-C$ single bond. Then, 30 electrons of the 48 available form aromatic bonds, two electrons form the bridging $C-C$ single bond, and 16 electrons form the eight $C-H$ single bonds. The energies of the aromatic carbons are given by the same equations as those of benzene (Eqs. (15.51), (15.1-15.5), and (15.165-15.166)), except that there are 10 in naphthalene versus six in benzene. Since there are three electrons per aromatic bond, $c_{4}$ is three times ten, the number of aromatic bonds. Similarly, the aromatic $C-H$ group of naphthalene is equivalent to that of benzene.

To meet the equipotential condition of the union of the ten $C 2 s p^{3}$ HOs bridged by the $C-C$ single bond, the parameters $c_{1}, C_{2}$, and $C_{2 o}$ of Eq. (15.51) are one for the $C-C$ group, $C_{1 o}$ and $C_{1}$ are 0.5 , and $c_{2}$ given by Eq. (15.161) is $c_{2}\left(C 2 s p^{3} H O\right)=0.85252$. Otherwise, the solutions of the $C-C$ bond parameters are equivalent to those of the replaced $C-H$ groups with $E(A O / H O)=-14.63489 \mathrm{eV}$ and $\Delta E_{H_{2} M O}(A O / H O)=-1.13379 \mathrm{eV}$ per carbon in Eq. (15.51). Similarly, the energy parameters are determined using Eqs. (15.61-15.65) with $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)=\frac{-1.13379 \mathrm{eV}}{2}$.

The symbols of the functional groups of naphthalene are given in Table 15.219. The corresponding designation of the structure is shown in Figure 15.37B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of naphthalene are given in Tables 15.220, 15.221, and 15.222, respectively. The total energy of naphthalene given in Table 15.223 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.222 corresponding to functional-group composition of the molecule. The bond angle parameters of naphthalene determined using Eqs. (15.88-15.117) are given in Table 15.224. The color scale, translucent view of the chargedensity of naphthalene, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.37A. The polycyclic aromatic hydrocarbon pentacene was imaged by atomic force microscopy using a single CO molecule as the probe [53]. The resulting breakthrough in resolution revealed that in contrast to the fuzzy images touted by quantum theoreticians as proof of the cloud model of the electron, the images showed localized bonding MOs and AOs in agreement with the classical solution as shown in Figure 15.38.

Figure 15.37. (A) Color scale, translucent view of the charge-density of naphthalene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of naphthalene.

## TOLUENE

Toluene has the formula $C_{7} H_{8}$ and comprises the benzene molecule with one hydrogen atom replaced by a methyl group corresponding to a $\mathrm{CH}_{3}$ functional group and a $\mathrm{C}-\mathrm{C}$ functional group. The aromatic $C=\stackrel{3 e}{=} C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The $\mathrm{CH}_{3}$ functional group is the same as that of continuous and branched-chain alkanes given in the corresponding sections.

The bond between the methyl and aromatic ring comprises a $C-C$ functional group that is solved using the same principles as those used to solve the alkane functional groups wherein the $2 s$ and $2 p$ AOs of each $C$ hybridize to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ HOs to form a MO permits each participating hybridized orbital to decrease in radius and energy. To match energies within the MO that bridges methyl and aromatic carbons, $E(A O / H O)$ and $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}(\mathrm{AO} / \mathrm{HO})$ in Eq. (15.50) are -15.35946 eV (Eq. (14.155)) and $\frac{-1.13379 \mathrm{eV}}{2}$, respectively.

To meet the equipotential condition of the union of the aromatic and methyl $C 2 s p^{3} \mathrm{HOs}$ of the $C-C$ single bond, the parameters $c_{1}, C_{2}$, and $C_{2 o}$ of Eq. (15.51) are one for the $C-C$ group, $C_{1 o}$ and $C_{1}$ are 0.5 , and $c_{2}$ given by Eq. (13.430) is $c_{2}\left(C 2 s p^{3} H O\right)=0.91771$. To match the energies of the functional groups, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} \cdot A O\right)$ of the $C-C$-bond MO in Eq. (15.61) due to the charge donation from the $C$ atoms to the MO is -1.13379 eV which is the same energy per $C 2 s p^{3} \mathrm{HO}$ as that of the replaced $C-H$ group.

The symbols of the functional groups of toluene are given in Table 15.225. The corresponding designation of the structure is shown in Figure 15.39B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of toluene are given in Tables 15.226, 15.227, and 15.228, respectively. The total energy of toluene given in Table 15.229 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.228 corresponding to functional-group composition of the molecule. The bond angle parameters of toluene determined using Eqs. (15.88-15.117) are given in Table 15.230. The color scale, translucent view of the charge-density of toluene comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.39A.

## HALOBENZENES

Halobenzenes have the formula $C_{6} H_{6-m} X_{m} \quad X=F, C l, B r, I$ and comprise the benzene molecule with at least one hydrogen atom replaced by a halogen atom corresponding to a $C-X$ functional group. The aromatic $C={ }^{3 e} C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The hybridization factors of the aryl $C-X$ functional groups are equivalent to those of the corresponding alkyl halides as given in Tables $15.30,15.36,15.42$, and 15.48 , and are solved using the same principles as those used to solve the alkyl halide functional groups as given in the corresponding sections. In each case, the $2 s$ and $2 p$ AOs of each $C$ hybridize to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and $X$ AO to form a MO permits each participating hybridized orbital to decrease in radius and energy. Therefore, the MO is energy matched to the $C 2 s p^{3} \mathrm{HO}$ such that $E(A O / H O)$ in Eq. (15.51) is $-14.63489 \mathrm{eV} . E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of each $C-X$ functional group given in Table 15.234 that achieves matching of the energies of the AOs and HOs within the functional groups of the MOs are those of alkanes and alkenes given in Tables 15.1 and 15.2. To further match energies within each MO that bridges the halogen AO and aromatic carbon $C 2 s p^{3} \mathrm{HO}$, $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}(\mathrm{AO} / \mathrm{HO})$ in Eq. (15.51) is $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . \mathrm{AO}\right)$ of the alkene $C=C$ functional group, -2.26759 eV given by Eq. (14.247), plus the maximum possible contribution of $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-X$ functional group to minimize the energy of the MO as given in Table 15.234. $E_{\text {initial }}\left(c_{4} A O / H O\right)$ is -14.63489 eV (Eq. (15.25)), except for $C-I$ due to the low ionization potential of the $I \mathrm{AO}$. In order to achieve an energy minimum with energy matching within iodo-aryl molecules, $E_{\text {initial }}\left(c_{4} \mathrm{AO} / \mathrm{HO}\right)$ of the $C-I$ functional group is -15.76868 eV (Eq. (14.246)), and $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}{ }^{3} . \mathrm{AO}\right)$ is -1.65376 eV given by the linear combination of -0.72457 eV (Eq. (14.151)) and -0.92918 eV (Eq. (14.513)), respectively.

The small differences between energies of ortho, meta, and para-dichlorobenzene is due to differences in the energies of vibration in the transition state that contribute to $E_{o s c}$. Two types of $\mathrm{C}-\mathrm{Cl}$ functional groups can be identified based on symmetry that determine the parameter $R$ in Eq. (15.57). One corresponds to the special case of $1,3,5$ substitution and the other corresponds to other cases of single or multiple substitutions of Cl for H . P-dichlorobenzene is representative of the bonding with $R=a$. 1,2,3-trichlorobenzene is the particular case wherein $R=b$. Also, beyond the binding of three chlorides $E_{\operatorname{mag}}$ is subtracted for each additional Cl due to the formation of an unpaired electrons on each $\mathrm{C}-\mathrm{Cl}$ bond.

The symbols of the functional groups of halobenzenes are given in Table 15.231. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of halobenzenes are given in Tables $15.232,15.233$, and 15.234 , respectively. The total energy of each halobenzene given in Table 15.235 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.234 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C 2 s p^{3} \mathrm{HO}$ magnetic energy $E_{\text {mag }}$ that is subtracted from the weighted sum of the $E_{D}($ Group $)(\mathrm{eV})$ values based on composition is given by Eq. (15.67). The bond angle parameters of halobenzenes determined using Eqs. (15.88-15.117) are given in Table 15.236. The color scale, translucent view of the charge-density of chlorobenzene comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.40.

Figure 15.40. Color scale, translucent view of the charge-density of chlorobenzene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## PHENOL

Phenol has the formula $\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}$ and comprises the benzene molecule with one hydrogen atom replaced by a hydroxyl corresponding to an $O H$ functional group and a $C-O$ functional group. The aromatic $C=\frac{3 e}{=} C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The $O H$ functional group is the same as that of alcohols given in the corresponding section.

The bond between the hydroxyl and aromatic ring comprises a $C-O$ functional group that is solved using the same principles as those used to solve the alcohol functional groups wherein the $2 s$ and $2 p$ AOs of each $C$ hybridize to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and $O$ AO to form a MO permits each participating hybridized orbital to decrease in radius and energy. In aryl alcohols, the aromatic $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.85252 (Eq. (15.162)) with an initial energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)) and the $O$ AO has an energy of $E(O)=-13.61806 \mathrm{eV}$. To meet the equipotential condition of the union of the $\mathrm{C}-\mathrm{O} \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.61) for the $C-O$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{equation*}
c_{2}\left(\text { arylC2sp }{ }^{3} \mathrm{HO} \text { to } O\right)=\frac{E(O)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(\operatorname{arylC} 2 s p^{3} \mathrm{HO}\right)=\frac{-13.61806 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.85252)=0.79329 \tag{15.169}
\end{equation*}
$$

$E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ of the $C-O$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $O$ atoms to the MO is -1.49608 eV . It is based on the energy match between the OH group and the $C 2 s p^{3} \mathrm{HO}$ of an aryl group and is given by the linear combination of -0.92918 eV (Eq. (14.513)) and -1.13379 eV (Eq. (14.247)), respectively.

The symbols of the functional groups of phenol are given in Table 15.237. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of phenol are given in Tables $15.238,15.239$, and 15.240 , respectively. The total energy of phenol given in Table 15.241 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.240 corresponding to functional-group composition of the molecule. The bond angle parameters of phenol determined using Eqs. (15.88-15.117) are given in Table 15.242. The color scale, translucent view of the charge-density of phenol comprising the concentric shells of atoms with the outer shell bridged by one or more $\mathrm{H}_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.41.

Figure 15.41. Color scale, translucent view of the charge-density of phenol showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## ANILINE

Aniline and methyl aniline have the formula $\mathrm{C}_{6} \mathrm{H}_{7} \mathrm{~N}$ and $\mathrm{C}_{7} \mathrm{H}_{9} \mathrm{~N}$, respectively. They comprise the benzene and toluene molecules with one hydrogen atom replaced by an amino group corresponding to an $\mathrm{NH}_{2}$ functional group and a $\mathrm{C}-\mathrm{N}$ functional group. The aromatic $C \stackrel{3 e}{=} C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The $\mathrm{C}-\mathrm{C}$ and $\mathrm{CH}_{3}$ functional groups of methyl anilines are equivalent to those of toluene given in the corresponding section.

The aryl amino $\left(\mathrm{NH}_{2}\right)$ functional group was solved using the procedure given in the Dihydrogen Nitride $\left(\mathrm{NH}_{2}\right)$ section. Using the results of Eqs. (13.245-13.368), the aryl amino parameters in Eq. (15.60) are $n_{1}=2, C_{1}=0.75, C_{2}=0.93613$ (Eqs. (13.248-13.249)), $C_{1 o}=1.5$, and $c_{1}=0.75$. In the determination of the hybridization factor $c_{2}$ of Eq. (15.61) for the $N-H-$ bond MO of aryl amines, the $C 2 s p^{3} \mathrm{HO}$ of the $\mathrm{C}-\mathrm{NH}_{2}$-bond MO has an energy of $E\left(C, 2 s p^{3}\right)=-15.76868 \mathrm{eV}$ (Eq. (15.18)) corresponding to $s=2$ in Eqs. (15.18-15.20), and the $N \mathrm{AO}$ has an energy of $E(N)=-14.53414 \mathrm{eV}$. To meet the equipotential condition of the union of the $\mathrm{N}-\mathrm{H}_{2} \quad \mathrm{H}_{2}$-type-ellipsoidal-MO with the $\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO}$, the hybridization factor $c_{2}$ given by Eq. (15.77) is:

$$
\begin{equation*}
c_{2}(H \text { to aniline } N)=\frac{E(N)}{E\left(C, 2 s p^{3}\right)}=\frac{-14.53414 \mathrm{eV}}{-15.76868 \mathrm{eV}}=0.92171 \tag{15.170}
\end{equation*}
$$

The bond between the amino and aromatic ring comprises a $C-N$ functional group that is the same as that of $2^{\circ}$ amines (methylene) except that the energies corresponding to oscillation in the transition state are those of aniline. The group is solved using the same principles as those used to solve the primary and secondary-amine functional groups wherein the $2 s$ and $2 p$ AOs of each $C$ hybridize to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3}$ HO and $N \mathrm{AO}$ to form a MO permits each participating hybridized orbital to decrease in radius and energy. The hybridization is determined in a similar manner to that of the $C-O$ group of phenol. In anilines, the aromatic $C 2 s p^{3} \mathrm{HO}$ has a hybridization factor of 0.85252 (Eq. (15.162)) with an initial energy of $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$ (Eq. (15.25)) and the $N$ AO has an energy of $E(N)=-14.53414 \mathrm{eV}$. To meet the equipotential condition of the union of the $\mathrm{C}-\mathrm{N} \mathrm{H}_{2}$-type-ellipsoidal-MO with these orbitals, the hybridization factor $c_{2}$ of Eq. (15.60) for the $C-N$-bond MO given by Eqs. (15.77) and (15.79) is:

$$
\begin{align*}
c_{2}\left(\text { arylC } 2 s p^{3} \mathrm{HO} \text { to } \mathrm{N}\right) & =\frac{E(N)}{E\left(C, 2 s p^{3}\right)} c_{2}\left(\text { arylC } 2 s p^{3} \mathrm{HO}\right) \\
& =\frac{-14.53414 \mathrm{eV}}{-14.63489 \mathrm{eV}}(0.85252)  \tag{15.171}\\
& =0.84665
\end{align*}
$$

$E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-N$-bond MO in Eq. (15.61) due to the charge donation from the $C$ and $N$ atoms to the MO is -1.13379 eV (Eq. (14.247)). It is based on the energy match between the $\mathrm{NH}_{2}$ group and the $\mathrm{C} 2 \mathrm{sp}{ }^{3} \mathrm{HO}$ of the aryl group and is twice that of the aryl $C-H$ group that it replaces.

The symbols of the functional groups of aniline and methyl-substituted anilines are given in Table 15.243. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of aniline and methyl-substituted anilines are given in Tables 15.244, 15.245, and 15.246, respectively. The total energy of each aniline and methyl-substituted aniline given in Table 15.247 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.246 corresponding to functional-group composition of the molecule. The bond angle parameters of aniline and methyl-substituted anilines determined using Eqs. (15.88-15.117) are given in Table 15.248. The color scale, translucent view of the charge-density of aniline comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.42.

Figure 15.42. Color scale, translucent view of the charge-density of aniline showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## ARYL NITRO COMPOUNDS

Aryl nitro compounds have a hydrogen of an aryl group replaced by a nitro corresponding to an $\mathrm{NO}_{2}$ functional group and a $C-N$ functional group. Examples include nitrobenzene, nitrophenol, and nitroaniline with formulas $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NO}_{2}, \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NO}_{3}$, and $C_{6} H_{6} N_{2} O_{2}$, respectively. The aromatic $C \stackrel{3 e}{=} C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The $O H$ and $C-O$ functional groups of nitrophenols are the same as those of phenol given in the corresponding section. The $\mathrm{NH}_{2}$ and $\mathrm{C}-\mathrm{N}$ functional groups of nitroanilines are the same as those of aniline given in the corresponding section. The differences between the total bond energies of the nitroanilines given in Table 15.252 are due to differences in the $E_{\text {osc }}$ term. For simplicity and since the differences are small, the $E_{\text {osc }}$ terms for nitroanilines were taken as the same.

The $\mathrm{NO}_{2}$ group is the same as that given in the Nitroalkanes section. The bond between the nitro and aromatic ring comprises a $C-N$ functional group that is the same as that of nitroalkanes given in the corresponding section except that $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ is -0.72457 eV , one half of that of the $C-N$-bond MO of nitroalkanes and equivalent to that of methyl (Eq. (14.151)) in order to maintain the independence and aromaticity of the benzene functional group. In addition, the energy terms due to oscillation in the transition state correspond to those of an aryl nitro compound.

The symbols of the functional groups of aryl nitro compounds are given in Table 15.249. The geometrical (Eqs. (15.115.5 ) and (15.42)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of aryl nitro compounds are given in Tables $15.250,15.251$, and 15.252 , respectively. The total energy of each aryl nitro compound given in Table 15.253 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.252 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C 2 s p^{3}$ HO magnetic energy $E_{\text {mag }}$ that is subtracted from the weighted sum of the $E_{D}$ (Group) (eV) values based on composition is given by Eq. (15.67). The bond angle parameters of aryl nitro compounds determined using Eqs. (15.88-15.117) are given in Table 15.254. The color scale, translucent view of the charge-density of exemplary aryl nitro, nitrobenzene, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.43.

Figure 15.43. Color scale, translucent view of the charge-density of nitrobenzene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

## BENZOIC ACID COMPOUNDS

Benzoic acid compounds have a hydrogen of an aryl group replaced by a carboxylic acid group corresponding to an $C-C(O)-O H$ moiety that comprises $C=O$ and $O H$ functional groups that are the same as those of carboxylic acids given in the corresponding section. The single bond of aryl carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. This group is also equivalent to the same group of carboxylic acids except that $\Delta E_{H_{2} M O}(A O / H O)$ in Eq. (15.51) and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ in Eq. (15.61) are both -1.29147 eV which is a linear combination of $\frac{-1.13379 \mathrm{eV}}{2}$, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C-H$ group that the $C-C(O)$ group replaces, and that of an independent $C 2 s p^{3} \mathrm{HO}$, -0.72457 eV (Eq. (14.151)).

Examples include benzoic acid, chlorobenzoic acid, and aniline carboxylic acid with formulas $\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{2}, \mathrm{C}_{7} \mathrm{H}_{5} \mathrm{O}_{2} \mathrm{Cl}$, and $\mathrm{C}_{7} \mathrm{H}_{7} \mathrm{NO}_{2}$, respectively. The aromatic $\mathrm{C}=\mathrm{C}=\mathrm{C}$ and $\mathrm{C}-\mathrm{H}$ functional groups are equivalent to those of benzene given in Aromatic and Heterocyclic Compounds section. The $\mathrm{NH}_{2}$ and $\mathrm{C}-\mathrm{N}$ functional groups of aniline carboxylic acids are the same as those of aniline given in the corresponding section. The $\mathrm{C}-\mathrm{Cl}$ functional group of 2-chlorobenzoic acids corresponding to meta substitution is equivalent to that of chlorobenzene given in the corresponding section. The $\mathrm{C}-\mathrm{Cl}$ functional group of 3 or 4 -chlorobenzoic acids corresponding to ortho and para substitution is also equivalent to that of chlorobenzene, except that $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ in Eq. (15.61) is -0.92918 eV (Eq. (14.513)) for both cases since each of these positions can form a resonance structure with the carboxylic acid group which is permissive of greater charge donation from the $C 2 s p^{3} \mathrm{HO}$.

The symbols of the functional groups of benzoic acid compounds are given in Table 15.255. The corresponding designations of benzoic acid is shown in Figure 15.44B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.8015.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of benzoic acid compounds are given in Tables $15.256,15.257$, and 15.258 , respectively. The total energy of each benzoic acid compound given in Table 15.259 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.258 corresponding to functional-group composition of the molecule. The bond angle parameters of benzoic acid compounds determined using Eqs. (15.88-15.117) are given in Table 15.260. The color scale, translucent view of the charge-density of benzoic acid comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.44A.

Figure 15.44. (A) Color scale, translucent view of the charge-density of benzoic acid showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of benzoic acid.

Table 15.255. The symbols of functional groups of benzoic acid compounds.

| Functional Group | Group Symbol |
| :--- | :--- |
| CC (aromatic bond) | $\mathrm{C}=\mathrm{C}$ |
| CH (aromatic) | CH (i) |
| $\mathrm{C}-\mathrm{C}(\mathrm{O})$ | $\mathrm{C}-\mathrm{C}(\mathrm{O})$ |
| $\mathrm{C}=\mathrm{O}$ (aryl carboxylic acid) | $\mathrm{C}=\mathrm{O}$ |

## ANISOLE

Anisole has the formula $\mathrm{C}_{7} \mathrm{H}_{8} \mathrm{O}$ and comprises the phenol molecule with the hydroxyl hydrogen atom replaced by the moiety $-\mathrm{O}-\mathrm{CH}_{3}$ to form an ether comprising aromatic and methyl functional groups as well as two types of $\mathrm{C}-\mathrm{O}$ functional groups, one for aryl carbon to oxygen and one for methyl carbon to oxygen. The aromatic $C=C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The $\mathrm{CH}_{3}$ and methyl $\mathrm{C}-\mathrm{O}$ functional groups are the same as those of the corresponding ether groups given in the corresponding section.

The $C-O$ functional group comprising the bond between the ether oxygen and aromatic ring is equivalent to that of the methyl ether $C-O$ functional group except that $\Delta E_{\mathrm{H}_{2} M O}(A O / H O)$ in Eq. (15.51) and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ in Eq. (15.61) are both -1.13379 eV (Eq. (14.247)). $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . \mathrm{AO}\right)$ is based on the energy match between the $\mathrm{OCH}_{3}$ group and the $C 2 s p^{3} \mathrm{HO}$ of the aryl group and is twice that of the aryl $C-H$ group that it replaces.

The symbols of the functional groups of anisole are given in Table 15.261. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of anisole are given in Tables $15.262,15.263$, and 15.264 , respectively. The total energy of anisole given in Table 15.265 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.264 corresponding to functional-group composition of the molecule. The bond angle parameters of anisole determined using Eqs. (15.88-15.117) are given in Table 15.266. The color scale, translucent view of the charge-density of anisole comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.45.

Figure 15.45. Color scale, translucent view of the charge-density of anisole showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

$0 \square 1 \mathrm{e} / \AA^{2}$

Table 15.261. The symbols of functional groups of anisole.

| Functional Group | Group Symbol |
| :--- | :--- |

## PYRROLE

Pyrrole having the formula $\mathrm{C}_{4} \mathrm{H}_{5} \mathrm{~N}$ comprises the conjugated alkene 1,3-butadiene that forms a cyclic structure by terminalatom bonding to a $N H$ functional group. The two symmetrical carbon-to-nitrogen bonds comprise the $C-N-C$ functional group. The 1,3 -butadiene moiety comprises $C-C, C=C$, and $C H$ functional groups. The $C-C$ and $C=C$ groups are equivalent to the corresponding groups of 1,3-butadiene given in the Cyclic and Conjugated Alkenes section except that the energy terms corresponding to oscillation in the transition state match pyrrole. Furthermore, the conjugated double bonds have the same bonding as in 1,3-butadiene except that the hybridization terms $c_{2}$ of the $C-C$ and $C=C$ groups and $C_{2}$ and $C_{2 o}$ of the $C=C$ group in Eqs. (15.51) and (15.61) become that of benzene given by Eq. (15.162), $\left(C_{2}\left(\right.\right.$ benzene $\left.2 s p^{3} \mathrm{HO}\right)=c_{2}\left(\right.$ benzene $\left.C 2 s p^{3} \mathrm{HO}\right)=0.85252$ ), in the cyclic pyrrole MO which has aromatic character. The bonding in pyrrole, furan, and thiophene are the same except for the energy match to the corresponding heteroatoms. The hybridization permits double-bond character in the carbon-heteroatom bonding.

The $N H$ group is solved equivalently to that of a secondary amine as given in the corresponding section except that the hybridization term $c_{2}$ is that of the amino group of aniline in order provide double-bond character to match the group to the other orbitals of the molecule. Similarly, the CH functional group is equivalent to that of 1,3-butadiene, except that $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}(\mathrm{AO} / \mathrm{HO})=-2.26758 \mathrm{eV}$ (Eq. (14.247)) in Eq. (15.51) in order to provide matching double-bond character.

The solution of the $C-N-C$ functional group comprises the hybridization of the $2 s$ and $2 p$ AOs of each $C$ to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ HOs and the nitrogen atom to form a MO permits each participating hybridized orbital to decrease in radius and energy. Thus, the $C-N-C$-bond MO comprising a linear combination of two single bonds is solved in the same manner as a double bond with $n_{1}=2$ in Eqs. (15.51) and (15.61). The hybridization factor $c_{2}\left(\operatorname{arylC} 2 s p^{3} \mathrm{HO}\right.$ to $\left.N\right)=0.84665$ (Eq. (15.171)) matches the double-bond character of the $C 2 s p^{3}$ HOs to the $N$ atom of the $N H$ group, and $C_{2}$ and $C_{20}$ in Eqs. (15.51) and (15.61) become that of benzene given by Eq. (15.162), $C_{2}\left(\right.$ benzene $\left.C 2 s p^{3} H O\right)=0.85252$. Furthermore, $\Delta E_{H_{2} M O}(A O / H O)$ in Eq. (15.51) and $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ in Eq. (15.61) are both -0.92918 eV (Eq. (14.513)) per atom corresponding to -3.71673 eV in total. This is the maximum energy for a single bond and corresponds to methylene character as given in the Continuous-Chain Alkanes section.
The symbols of the functional groups of pyrrole are given in Table 15.267. The structure of pyrrole is shown in Figure 15.46B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of pyrrole are given in Tables $15.268,15.269$, and 15.270 , respectively. The total energy of pyrrole given in Table 15.271 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.270 corresponding to functional-group composition of the molecule. The bond angle parameters of pyrrole determined using Eqs. (15.88-15.117) are given in Table 15.272. The color scale, translucent view of the charge-density of pyrrole comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.46A.

Figure 15.46. (A) Color scale, translucent view of the charge-density of pyrrole showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of pyrrole.

Table 15.271. The total bond energies of pyrrole calculated using the functional group composition and the energies of Table 15.270 compared to the experimental values [3].

## FURAN

Furan having the formula $\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}$ comprises the conjugated alkene 1,3-butadiene that forms a cyclic structure by terminal-atom bonding to an oxygen atom. The two symmetrical carbon-to-oxygen bonds comprise the $C-O-C$ functional group. The 1,3butadiene moiety comprises $C-C, C=C$, and $C H$ functional groups. The $C H, C-C$, and $C=C$ groups are equivalent to the corresponding groups of pyrrole given in the corresponding section.

The $C-O-C$ functional group of furan is solved in a similar manner as that of the $C-N-C$ group of pyrrole. The solution of the $C-O-C$ functional group comprises the hybridization of the $2 s$ and $2 p$ AOs of each $C$ to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ HOs and the oxygen atom to form a MO permits each participating hybridized orbital to decrease in radius and energy. Thus, the $C-O-C$-bond MO comprising a linear combination of two single bonds is solved in the same manner as a double bond with $n_{1}=2$ in Eqs. (15.51) and (15.61). The hybridization factor $c_{2}\left(\right.$ arylC2sp ${ }^{3} \mathrm{HO}$ to O$)=0.79329$ (Eq. (15.169)) matches the double-bond character of the $C 2 s p^{3}$ HOs to the $O$ atom, and $C_{2}$ and $C_{2 o}$ in Eqs. (15.51) and (15.61) become that of benzene given by Eq. (15.162), $C_{2}\left(\right.$ benzene $\left.C 2 s p^{3} \mathrm{HO}\right)=0.85252$. Furthermore, $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ in Eq. (15.61) is -0.92918 eV (Eq. (14.513)) per atom corresponding to -3.71673 eV in total.

The symbols of the functional groups of furan are given in Table 15.273. The structure of furan is shown in Figure 15.47B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of furan are given in Tables $15.274,15.275$, and 15.276 , respectively. The total energy of furan given in Table 15.277 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.276 corresponding to functional-group composition of the molecule. The bond angle parameters of furan determined using Eqs. (15.88-15.117) are given in Table 15.278. The color scale, translucent view of the charge-density of furan comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.47A.

Figure 15.47. (A) Color scale, translucent view of the charge-density of furan showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of furan.

## THIOPHENE

Thiophene having the formula $\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{~S}$ comprises the conjugated alkene 1,3-butadiene that forms a cyclic structure by terminalatom bonding to an oxygen atom. The two symmetrical carbon-to-sulfur bonds comprise the $C-S-C$ functional group. The 1,3-butadiene moiety comprises $C-C, C=C$, and $C H$ functional groups. The $C H, C-C$, and $C=C$ groups are equivalent to the corresponding groups of pyrrole and furan given in the corresponding sections.

The $C-S-C$ functional group of thiophene is solved in a similar manner as that of the $C-N-C$ group of pyrrole and the $C-O-C$ group of furan. The solution of the $C-S-C$ functional group comprises the hybridization of the $2 s$ and $2 p$ AOs of each $C$ to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between two $C 2 s p^{3}$ HOs and the sulfur atom to form a MO permits each participating hybridized orbital to decrease in radius and energy. Thus, the $C-S-C$-bond MO comprising a linear combination of two single bonds is solved in the same manner as a double bond with $n_{1}=2$ in Eqs. (15.51) and (15.61).

In thiophene, the energy of sulfur is less than the Coulombic energy between the electron and proton of $H$ given by Eq. (1.264). Thus, $c_{2}$ in Eq. (15.61) is $c_{2}\left(\right.$ benzene $\left.C 2 s p^{3} \mathrm{HO}\right)=0.85252$ to match the double-bond character of the $C 2 s p^{3} \mathrm{HOs}$, and the energy matching condition is further determined by the $C_{2}$ parameter. Using the energy of $S, E(S)=-10.36001 \mathrm{eV}$ in Eq. (15.77) and the $C 2 s p^{3}$ HO energy of $E\left(C, 2 s p^{3}\right)=-15.76868 \mathrm{eV}$ (Eq. (15.18)) corresponding to $s=2$ in Eqs. (15.18-15.20), the hybridization factor $C_{2}$ of Eq. (15.61) for the $C-S-C$-bond MO is:

$$
\begin{equation*}
C_{2}\left(S 3 p \text { to aryl-type } C 2 s p^{3} \mathrm{HO}\right)=\frac{E(S, 3 p)}{E\left(C, 2 s p^{3}\right)}=\frac{-10.36001 \mathrm{eV}}{-15.76868 \mathrm{eV}}=0.65700 \tag{15.172}
\end{equation*}
$$

$C_{1 o}$ is also given by Eq. (15.172). Furthermore, $\Delta E_{H_{2} M O}(A O / H O)$ of the $C-S-C$-bond MO in Eq. (15.51) and $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . \mathrm{AO}\right)$ in Eq. (15.61) are both -0.72457 eV per atom corresponding to -2.89830 eV in total. The energy contribution equivalent to that of a methyl group (Eq. (14.151)) and that of the $C-S$-bond MO of thiols given in the corresponding section matches the energy of the sulfur atom to the $C 2 s p^{3} \mathrm{HOs}$.

The symbols of the functional groups of thiophene are given in Table 15.279. The structure of thiophene is shown in Figure 15.48B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of thiophene are given in Tables $15.280,15.281$, and 15.282 , respectively. The total energy of thiophene given in Table 15.283 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.282 corresponding to functional-group composition of the molecule. The bond angle parameters of thiophene determined using Eqs. (15.88-15.117) are given in Table 15.284. The color scale, translucent view of the charge-density of thiophene comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.48A.

## IMIDAZOLE

Imidazole having the formula $\mathrm{C}_{3} \mathrm{H}_{4} N_{2}$ comprises a conjugated system that is equivalent to pyrrole with one of the conjugated CH groups replaced by a nitrogen atom. The $\mathrm{CH}, \mathrm{NH}$, and $\mathrm{C}=\mathrm{C}$ groups are equivalent to the corresponding groups of pyrrole, furan, and thiophene where present. In addition, the nitrogen substitution creates a $C-N=C$ moiety comprising $C-N$ and $N=C$ functional groups. The $C-N$ bonding is the same as that of a tertiary amine except that the hybridization term $c_{2}$ in Eqs. (15.51) and (15.61) is that of the amino group of aniline, $c_{2}\left(\operatorname{arylC} 2 s p^{3} \mathrm{HO}\right.$ to $\left.N\right)=0.84665$ (Eq. (15.171)). The hybridization factor provides double-bond character to match the group to the other orbitals of the molecule. $\Delta E_{\mathrm{H}_{2} \mathrm{MO}}(\mathrm{AO} / \mathrm{HO})$ in Eq. (15.51) and $E_{T}\left(\right.$ atom-atom, $\left.\mathrm{msp}^{3} . A O\right)$ in Eq. (15.61) are both -0.92918 eV (Eq. (14.513)). This matches the energy of the group to that of the contiguous $N=C$ group wherein $\Delta E_{H_{2} M O}(A O / H O)$ in Eq. $(15.51)$ and $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ in Eq. (15.61) are both -0.92918 eV (Eq. (14.513)) per atom of the double bond with aromatic character as in the case of the prior heterocyclic compounds. As in the prior cases of pyrrole, furan, and thiophene, $n_{1}=2$ and $C_{2}$ and $C_{20}$ are the same as $C_{2}\left(\right.$ benzene $\left.C 2 s p^{3} H O\right)=0.85252$ (Eq. (15.162)) in Eqs. (15.51) and (15.61). To match the energy of the nitrogen to the $C 2 s p^{3}$ $\mathrm{HO}, c_{2}$ of the $N=C$-bond MO is also given by Eq. (15.171). These parameters also provide an energy match to the $C-N-C$ group.

As in the case of pyrrole, the $C-N-C$-bond MO comprising a linear combination of two single bonds is solved in the same manner as a double bond with $n_{1}=2$ in Eqs. (15.51) and (15.61). The hybridization factor $c_{2}\left(\operatorname{arylC} 2 s p^{3} \mathrm{HO}\right.$ to $\left.N\right)=0.84665$ (Eq. (15.171)) matches the double-bond character of the $C 2 s p^{3}$ HOs to the $N$ atom of the NH group, and $C_{2}$ and $C_{2 o}$ in Eqs. (15.51) and (15.61) become that of benzene given by Eq. (15.162), $C_{2}\left(\right.$ benzene $\left.C 2 s p^{3} H O\right)=0.85252$. Furthermore, $\Delta E_{H_{2} M O}(A O / H O)$ in Eq. (15.51) and $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3} . A O\right)$ in Eq. (15.61) are both -0.92918 eV (Eq. (14.513)) per atom corresponding to -3.71673 eV in total.

The symbols of the functional groups of imidazole are given in Table 15.285. The structure of imidazole is shown in Figure 15.49B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of imidazole are given in Tables 15.286, 15.287, and 15.288, respectively. The total energy of imidazole given in Table 15.289 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.288 corresponding to functional-group composition of the molecule. The bond angle parameters of imidazole determined using Eqs. (15.88-15.117) are given in Table 15.290 . The color scale, translucent view of the charge-density of imidazole, comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.49A.

Figure 15.49. (A) Color scale, translucent view of the charge-density of imidazole showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). ## PYRIDINE

Pyridine has the formula $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$ and comprises the benzene molecule with one CH group replaced by a nitrogen atom which gives rise to a $C \stackrel{3 e}{=} N$ functional group. The aromatic $C \stackrel{3 e}{=} C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section with the aromaticity maintained by the electrons from nitrogen in the $C \stackrel{3 e}{=} N$ group, which is also aromatic.

As in the case of the aromatic carbons of benzene, each pyridine $C 2 s p^{3} \mathrm{HO}$ initially has four unpaired electrons. Each $C-H$ bond has two paired electrons with one donated from the $H \mathrm{AO}$ and the other from the $C 2 s p^{3} \mathrm{HO}$. In pyridine the three $N 2 p$ electrons are donated to the aromatic bond. Thus, as in the case of the $C \stackrel{3 e}{=} C$ group, each $C=N$ bond comprises a linear combination of a factor of 0.75 of four paired electrons (three electrons) from the $C 2 s p^{3} \mathrm{HO}$ and the $N 2 p$ AO of the participating carbon and nitrogen atoms, respectively.

The solution of the $C \stackrel{3 e}{=} N$ functional group comprises the hybridization of the $2 s$ and $2 p$ AOs of each $C$ to form a single $2 s p^{3}$ shell as an energy minimum, and the sharing of electrons between the $C 2 s p^{3} \mathrm{HO}$ and the nitrogen atom to form a MO permits each participating hybridized orbital to decrease in radius and energy. The $C=N$-bond MO is solved as a double bond with $n_{1}=2$ in Eqs. (15.51) and (15.166). The hybridization factor $c_{2}\left(C 2 s p^{3} H O\right.$ to $\left.N\right)=0.91140$ (Eq. (15.135)) matches the double-bond character of the $C 2 s p^{3} \mathrm{HO}$ to the $N$ atom, and $C_{2}$ and $C_{2 o}$ in Eqs. (15.51) and (15.166) are also given by Eq. (15.135) in order to match the nitrogen to the aromatic $C 2 s p^{3} \mathrm{HO}$ such that $\Delta E_{H_{2} M O}(A O / H O)=0$ in Eq. (15.51). Furthermore, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$ of the $C \stackrel{3 e}{=} N$-bond MO in Eq. (15.166) due to the charge donation from the $C$ and $N$ atoms to the MO is -1.44915 eV corresponding to an energy contribution from each atom that is equivalent to that of an independent methyl group, -0.72457 eV (Eq. (14.151)). The contributions are also the same as those for a primary amine group as given in the corresponding section. As in the case of benzene, the aromatic $E_{T}$ (Group $)$ and $E_{D}$ (Group) are given by Eqs. (15.165) and (15.166), respectively, with $f_{1}=0.75$. The breakage of the $C N C$ bonds results in three unpaired electrons on the $N$ atom. Thus, the corresponding $E_{\text {mag }}$ given by Eq. (15.69) was normalized for the two bonds per atom and for $f_{1}=0.75$ and was subtracted from the total energy of the $C \stackrel{3 e}{=} N$-bond MO in Eq. (15.166). The pyridine vibrational energies are similar to those of benzene [63]; thus, the value for benzene was used.

The symbols of the functional groups of pyridine are given in Table 15.291. The corresponding designation of the structure is shown in Figure 15.50B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of pyridine are given in Tables 15.292, 15.293, and 15.294, respectively. The total energy of pyridine given in Table 15.295 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.294 corresponding to functional-group composition of the molecule. The bond angle parameters of pyridine determined using Eqs. (15.88-15.117) are given in Table 15.296. The color scale, translucent view of the charge-density of pyridine comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.50A.

Figure 15.50. (A) Color scale, translucent view of the charge-density of pyridine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of pyridine.

## PYRIMIDINE

Pyrimidine has the formula $\mathrm{C}_{4} \mathrm{H}_{4} N_{2}$ and comprises the pyridine molecule with one additional CH group replaced by a nitrogen atom, which gives rise to a second $C \stackrel{3 e}{=} N$ functional group that is equivalent to that of pyridine given in the corresponding section. The aromatic $C \stackrel{3 e}{=} C$ and $C-H$ functional groups are also equivalent to those of pyridine and benzene given in the Aromatic and Heterocyclic Compounds section with the aromaticity maintained by the electrons from nitrogen in the $C=N$ group which is also aromatic.

The symbols of the functional groups of pyrimidine are given in Table 15.297. The corresponding designation of the structure is shown in Figure 15.51B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of pyrimidine are given in Tables 15.298, 15.299, and 15.300, respectively. The total energy of pyrimidine given in Table 15.301 was calculated as the sum over the integer multiple of each $E_{D}($ Group $)$ of Table 15.300 corresponding to functional-group composition of the molecule. The bond angle parameters of pyrimidine determined using Eqs. (15.88-15.117) are given in Table 15.302. The color scale, translucent view of the chargedensity of pyrimidine comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.51A.

Figure 15.51. (A) Color scale, translucent view of the charge-density of pyrimidine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of pyrimidine.

## PYRAZINE

Pyrazine has the formula $\mathrm{C}_{4} \mathrm{H}_{4} N_{2}$ and comprises the pyrimidine molecule with para rather than ortho aromatic nitrogen atoms. The $C \stackrel{3 e}{=} N$ functional group is equivalent to that of pyrimidine and pyridine given in the corresponding sections. The aromatic $C \stackrel{3 e}{=} C$ and $C-H$ functional groups are also equivalent to those of pyrimidine, pyridine, and benzene given in the Aromatic and Heterocyclic Compounds section with the aromaticity maintained by the electrons from nitrogen in the $C=N$ group, which is also aromatic.

The symbols of the functional groups of pyrazine are given in Table 15.303. The corresponding designation of the structure is shown in Figure 15.52B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of pyrazine are given in Tables 15.304, 15.305, and 15.306, respectively. The total energy of pyrazine given in Table 15.307 was calculated as the sum over the integer multiple of each $E_{D}$ (Group) of Table 15.306 corresponding to functional-group composition of the molecule. The bond angle parameters of pyrazine determined using Eqs. (15.88-15.117) are given in Table 15.308. The color scale, translucent view of the charge-density of pyrazine comprising the concentric shells of atoms with the outer shell bridged by one or more $H_{2}$-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.52A.

Figure 15.52. (A) Color scale, translucent view of the charge-density of pyrazine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each $H$ or $H_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of pyrazine.
